§ 1. Continuous and discrete manifoldnesses. Defined parts of a manifoldness are called Quanta. Division of the theory of continuous magnitude into the theories

(1) Of mere region-relations, in which an independence of magnitudes from position is not assumed;

(2) Of size-relations, in which such an independence must be assumed.

§ 2. Construction of the notion of a one-fold, two-fold, n-fold extended magnitude.

§ 3. Reduction of place-fixing in a given manifoldness to quantity-fixings. True character of an n-fold extended magnitude.

II. Measure-relations of which a manifoldness of n dimensions is capable on the assumption that lines have a length independent of position, and consequently that every line may be measured by every other.

§ 1. Expression for the line-element. Manifoldnesses to be called Flat in which the line-element is expressible as the square-root of a sum of squares of complete differentials.

§ 2. Investigation of the manifoldness of n-dimensions in which the line-element may be represented as the square root of a quadric differential. Measure of its deviation from flatness (curvature) at a given point in a given surface-direction. For the determination of its measure-relations it is allowable and sufficient that the curvature be arbitrarily given at every point in $n\frac{n-1}{2}$ surface directions.

§ 3. Geometric illustration.

§ 4. Flat manifoldnesses (in which the curvature is everywhere $= 0$) may be treated as a special case of manifoldnesses with constant curvature. These can also be defined as admitting an independence of n-fold extents in them from position (possibility of motion without stretching).

§ 5. Surfaces with constant curvature.

III. Application to Space.

§ 1. System of facts which suffice to determine the measure-relations of space assumed in geometry.

§ 2. How far is the validity of these empirical determinations probable beyond the limits of observation towards the infinitely great?

§ 3. How far towards the infinitely small? Connection of this question with the interpretation of nature.

THE DEVELOPMENT THEORY IN GERMANY*

III.

Chorology: or, the Geographical Distribution of Living Beings

THE importance of the theory of Evolution does not consist in its accounting for this or that particular fact, but in its explaining all biological facts collectively. It is found to be confirmed in every detail by the mode of distribution of the various organisms on the surface of the earth. This distribution had already been studied by Alexander von Humboldt and Fr. Schouw for plants, by Berghaus and Schmarda for animals. But previous to Darwin and Wallace, this study had produced only a collection of unsystematised facts; Haeckel has attempted to create out of it a special science under the name of *Chorology*.

With the exception of the monocellular protozoa, which, on account of their simplicity, have been able to appear at the same time or at several times in different places; with the exception also of species which owe their origin to a hybrid or bastard generation, and which it has been possible to reproduce in different circumstances wherever the parent species have previously spread, it must be admitted that each of the other species has only been originated a single time and in a single place. But, once produced, they must, as a consequence of the struggle for existence, and in virtue of the laws of population, or rather of excess of population, tend to spread to the widest possible extent. Animals and plants migrate as well as man, both actively and passively.

In the case of animals, which have, more than plants, freedom of movement, active migration plays the principal part. The more easy locomotion is in the case of any species, the more rapidly is the species bound to spread. This is why birds and insects, furnished with wings, although referable to a less number of orders or natural groups than other animals, yet present a very great diversity of species slightly distinguishable from one another; this is to be ascribed to the fact that the facility with which they can move from place to place has subjected them to the modifying influences of the most varied localities. After birds and insects the swiftest runners among the denizens of the land, the best swimmers among the inhabitants of the water have been subject to the widest extension. With regard to animals which are fixed or immovable while being developed, corals, tubicolæ, tunicata, crinoids, &c., they usually enjoy during their youth so much of the power of movement as admits of their displacement. A great number of floating plants are also transported to great distances by water.

But the spread of a large number of plants and of certain animals can be explained only by a passive migration. The wind sweeps to great distances, sometimes over seas, eggs of small animals, seeds, and sometimes even minute organisms; this explains the well-known phenomena of showers of frogs. These eggs, these seeds, these small organisms, sometimes fall into the water, which transports them to still greater distances. Trunks of trees, which traverse the ocean under the direction of the currents, and those which the tempest hurls from the mountain tops, can carry with them, hidden in their interstices, in the moss or the parasitical plants with which they are covered, in the earth which adheres to their roots, innumerable germs to be developed in new regions. The icebergs of the polar sea have landed foxes and bears even on the shores of Iceland and Britain. Birds, insects, mammals which are removed, carry with them thousands of parasites, microscopic beings, eggs or germs. Man himself carries them about more abundantly still along with the varied materials he employs for his works and his industry.

The fact of the distribution of certain species which cannot be explained by migration, either active or passive, may be accounted for by geological facts. In consequence of the im-

* Continued from vol. vii. p. 434.

perceptible but unceasing change of the level of the seas, in consequence of the phenomena of subsidence and elevation of the land, lands at one time united have been divided, watercourses which communicated have been separated, thus accounting for the fact that fishes of the same species are found in different rivers, that islands are tenanted by the same mammals as the continents. England has been united to Europe at two different times; at a certain epoch our continent must have been united by land to N. America. The South-sea Islands are the remains of what was at one time a single land; so in the Indian Ocean land has at one time stretched along the South of Asia from Sunda to Africa; this great continent which Sclater has called *Lemuria*, on account of the apes which were peculiar to it, is probably the cradle where the human race was developed from the anthropoid apes. Mr. Wallace has proved that the Malay Archipelago consisted of two entirely different parts: one, comprehending Borneo, Java, and Sumatra, was united to Asia by the peninsula of Malacca, while the other, comprehending the Celebes, the Moluccas, New Guinea, the Salomon Isles, &c., was immediately attached to Australia.

Another cause which has favoured the dispersion of species all over the globe, was the uniformity of temperature which prevailed up to the tertiary geological period. Previous to the freezing of the polar regions, species found everywhere a climate equally warm and agreeable, favourable to migrations in all directions; since that period, on the contrary, a new difficulty of existence has arisen,—organisms have to undergo acclimatisation; those which have the power of adapting themselves to the lower temperature of regions at a distance from the equator, have been transformed by selection into new species; while those which have found such adaptation impossible, have been compelled, under pain of extinction, to remove to more favourable climates. When, at a later period, occurred that strange phenomenon—of which, as yet, no satisfactory explanation has been given—known as the Glacial Period, animals and plants were compelled to migrate anew; the living population of the earth, condensing itself between the tropics, a terrible struggle for existence took place between the old inhabitants of these regions and those that fled thither for refuge; many species were bound to disappear, while many new ones were originated. There is still another chorological phenomenon which is to be accounted for by the glacial period, viz., the resemblance of many of the inhabitants of mountains to those of the Polar regions; as those animals and those plants are not found in the intermediate countries, it is absolutely necessary to suppose a migration which, considering the habits of these creatures, could only have taken place at the glacial epoch. It is probable that at this period the gentians, the saxifrages, the Polar hare and fox, inhabited the central part of Europe; but as the temperature rose, some of these creatures retired towards the north, while the remainder found a refuge upon the summits of the European mountains.

When plants or animals migrate to new regions, they are subjected to new conditions of existence to which they must adapt themselves. The new climate, new food, relations with new organisms, all this obliges the emigrants to submit to modifications under pain of annihilation, and, as a consequence, to form new varieties or new species; it is in these circumstances, in fact, that natural selection acts with the greatest intensity. In ordinary circumstances, individuals which have changed breed with individuals who have not changed, and the products of such crossings have a tendency to revert to the primitive type; but when a migration has taken place, when modified individuals are separated from the others by mountains or by seas, they can no longer interbreed, and this isolation insures the preservation of the newly acquired forms. It is of course evident that these considerations apply only to species in which the sexes are separate.

There still remain three other chorological phenomena which furnish an important proof of the truth of the evolution theory. There is first the likeness of form, the family resemblance which exists among the local species characteristic of each region, and the extinct and fossil species of the same region; in the second the no less striking family resemblance which exists among the inhabitants of certain groups of those of the neighbouring continents, whence the population of these islands must have come; and lastly, the special character presented by the collective fauna and flora of the islands. All the facts adduced by Darwin, Wallace,* and Moritz Wagner,† as well as all those other facts which geographical and topographical dispersion of organisms present to us are simply and completely explained by the theory of selection and migration, while it would be impossible to explain them without it.

* "Malay Archipelago."

† The "Darwinian Theory and the Law of Migration of Organisms" Leipzig, 1868).

Palæontology

Thanks to the theory of evolution, the natural classification of animals and plants, which was previously only a record of names for arranging the different forms in an artificial order, or a record of facts expressing summarily the degree of resemblance among them, tends to become the genealogical tree of organisms. In order to construct it the student has only to combine the data furnished by the three parallel developments referred to above—the palæontological development, the embryological development, and the systematic development in the order of perfection or of comparative anatomy. The writer in the *Révue Scientifique* here gives a table presenting a view of the geological and palæontological doctrines of Haeckel. Between the stages generally admitted by geologists, Haeckel intercalates others which he calls inferior or intermediate stages in relation to the superior stages. Haeckel accepts completely the system of gradual and continuous evolution as propounded by Lyell, and rejects the system of sudden catastrophes which has been advocated by Cuvier and his disciples. He places the probable appearance of man in the Miocene, and his certain existence in the Pliocene. Many attempts have been made to determine approximately how many thousand years each geological period has lasted; these conjectures are principally framed on the relative thickness of the different beds. The total thickness of the Archæolithic or Primordial beds, in which Haeckel includes the Laurentian, Cambrian, and Silurian, is 70,000 ft.; that of the Primary, from the Devonian to the Permian, 42,000 ft.; that of the Secondary, 15,000 ft.; that of the Tertiary, 3,000 ft.; while the thickness of the beds of the "Anthrooolithic" or Quaternary age is only from 500 to 700 ft. From these figures, the following relative duration of the successive ages may be deduced:—

Primordial Age . . .	53·6
Primary ,, . . .	32·1
Secondary ,, . . .	11·5
Tertiary ,, . . .	2·3
Quaternary ,, . . .	0·5

Thus the Primordial age has existed longer than the other four put together. As to the number of centuries or of millenniums necessary for the deposition of one bed only one foot thick, that depends on circumstances so variable that it is impossible to give any measure: it is longer in the depths of mid-ocean, in the beds of very long rivers, in lakes which receive no affluents; it is shorter on the sea-margins, at the mouths of great rivers whose course is long and straight, in lakes which receive many tributary streams. It results from such considerations that every estimate of the duration of a geological epoch must be relative.

It will be necessary, moreover, to take into consideration, elevations and depressions of the ground, which, according to Haeckel, will be alternative, and will correspond to the mineralogical and palæontological differences which exist between two systems of beds and between two formations of these systems. When a certain region, after having remained for many thousand centuries beneath the water, emerges for a certain time, and is again submerged, it will be readily admitted that the bed which is deposited after such an interval ought to present characteristics different from those of the lower bed: for time is bound to accomplish change of all organic and inorganic conditions. This theory has been disputed by Huxley, who finds it inconsistent with the existence of a large number of beds, in which are found united organic forms, holding a middle place between those of adjacent formations; the English naturalist adduces, for example, the beds of Saint Cassian, in which are found mingled the forms of the primary and secondary formations.

It is certain that even yet our knowledge of palæontology is very imperfect, and far from enabling us to write, with anything like exactness, the history of the production of organic species. We know with what difficulties this study is surrounded. The fossil remains of the most remote ages appear to have been destroyed by the great heat of the lower beds in which they were deposited. *Eozoon Canadense* is the only fossil which has hitherto been found in the formations of the Laurentian period; while the beds of carbon and of crystallised lime (graphite and marble) give us the assurance that in them have existed animal and vegetable petrifactions. Another difficulty lies in the fact that hitherto the field of geological exploration has been very re-

stricted. Outside of England, Germany, and France, very few formations have been seriously studied; almost the only successful explorations have been in railway-cuttings. One indication of what may be discovered elsewhere is furnished by the remarkable petrifactions which have resulted from some researches prosecuted in Africa and Asia, in the neighbourhood of the Cape, and on the Himalayas: forms have been discovered which fill up important gaps in palæontological classification. It must be remembered also that only the hard and solid parts of organisms have been preserved, that entire forms, such as the Medusæ, shell-less molluscs, many articulata, nearly all worms, could leave no trace behind. The most important parts of plants, the flowers, have completely disappeared. Moreover, terrestrial organisms have been petrified only in accidental instances, where they have fallen into the water and been covered with mud; it is not to be wondered at then if the number of fossils of this kind is relatively much less considerable than that of those kinds which have inhabited the sea or fresh water. This explains also the apparently strange fact that of many fossil mammals, especially those of the secondary, we recognise only the lower jaw. This arises from the fact that that bone is easily separated from the dead body; while the rest swims on the surface of the water and is carried to the bank, the jaw falls to the bottom, and is buried in the mud, where it is petrified. The traces of those which have been found in different beds of sandstone, and especially in the red sandstone of Connecticut, belong to organisms whose bodies are entirely unknown to us, and prove that we are far from possessing remains of all actual forms. What gives us reason to think that an immense number must remain unknown is the fact that of those whose fossil remains we possess, only one or two examples have come to light. It is only ten years since a bird of the highest importance was discovered in the Jura; till then no intermediate form was known between the birds proper and reptiles, which are, nevertheless, the class most closely related to the former. Now this fossil bird, which possesses the tail, not of an ordinary bird, but of a lizard, confirms the hypothesis that birds are descended from the saurians. A couple of small teeth which have been found in the Keuper of the Trias are, up to the present, the only proof that mammals have existed from the Triassic period, and that they did not appear only in the Jurassic period, as was previously believed.

Fortunately we are able to supplement the insufficient data of palæontology by those of embryology, since individual development is, as it were, a reproduction or recapitulation brief and rapid, by means of heredity and adaptation of the development of species. Embryology is especially valuable for the light which it throws on the more ancient forms of the primordial period; by it alone do we learn that these primitive forms must have been simple cells, similar to eggs; that these cells, by their segmentation, their conformation, and their division of labour, have given birth to the infinite variety of the most complicated organisms.

To the valuable data respecting the relations of organisms furnished by palæontology and embryology must be added those derived from comparative anatomy. When organisms, whose exterior is very different, resemble each other in their interior construction, we may conclude with certainty that this resemblance is due to heredity, while the differences are a result of adaptation. If, for example, we compare the limbs or extremities of different mammifers, the arm of man, the wing of the bat, the anterior members of the mole adapted for digging, those of other mammifers made for leaping, climbing, or running; if we consider, besides, that in all these members variously formed, the same bones are found, equal in number, in the same place, disposed in the same manner, are we not forced to admit the close relationship of organisms? This homology can be explained only by heredity, by descent from common ancestors. And to go still further, if we find in the wing of the bird, in the anterior members of reptiles and amphibia, the same bones as in the arms of man, or in the anterior limbs of other mammifers, can we not affirm with certainty the common descent of all these vertebrate animals?

SCIENTIFIC SERIALS

Ocean Highways, May.—The first paper in this number is an article on Mexico, by Mr. Maurice Kingsley, accompanied by a map showing the course of the Vera Cruz and Mexico Railway. This is followed by a very interesting article on "Railway Communication between London and Calcutta," with a map showing the proposed line from Ostende, by Vienna, Constantinople, Diabeker, Herat, Cabul, Lahore, Delhi, Cawnpore, and Calcutta. By this route the land journey would amount to 6,336 miles, with only 73 miles of sea, which could be accomplished in 214 hours, or about 9 days; while by the present shortest route, the sea-journey amounts to 3,941 miles, and the time taken is 492 hours, or upwards of 20 days. Dr. Robert Brown contributes a paper entitled "A Cruise with the Whalers in Baffin's Bay," which is followed by "Notes on Mr. Stanley's Work," by Capt. R. F. Burton, in which that gentleman points out several things in Stanley's book that he thinks are capable of amendment. Burton thinks Stanley "wants only study and discipline, to make him a first-rate traveller." This is followed by a very valuable paper on "The Steppes to the North of Bokhara," by A. Vámbéry. Then follow the usual reviews, notes, reports of societies, &c.

SOCIETIES AND ACADEMIES

London

Chemical Society, May 1.—Dr. Odling, F.R.S., president, in the chair.—Dr. H. Sprengel, "On a new class of explosives." gave an account of some new explosives consisting of two liquids inexplosive by themselves, but which when mixed and fired with a detonating charge are as effective as nitroglycerine.—Prof. Abel of the Royal Arsenal, Woolwich, drew attention to the great difference produced by variations in the mechanical state of the explosive.—On Zirconia, by Mr. J. B. Hannay.—On Pyrogallate of lead and lead salts, by Mr. W. H. Deering.

Royal Horticultural Society, April 16.—General meeting, Sir Coutts Lindsay, Bart., in the chair. The Rev. M. J. Berkeley commented on the plants exhibited, and remarked that the unused archways of railways might be profitably employed for the production of mushrooms.—Mr. W. A. Lindsay (the secretary) enumerated the concessions which the Council had made for this year to Her Majesty's commissioners for the Exhibition, including a passage-way across the gardens: the society would receive in return the sum of 1000*l*.—Scientific committee—Prof. Westwood, F.L.S., in the chair. The Rev. M. J. Berkeley commented on an article in the recent number of the journal of the Royal Agricultural Society on the injury suffered by horses fed upon mouldy oats. There was an evident error with respect to the fungus figured as *Aspergillum* (sic) which was clearly the common bread-mould *Ascophora Mucedo*. With respect to the diseased coffee-plants from Natal brought forward at the last meeting he was disposed to think that climatic conditions were the cause, of their malady. The differences between the summer and winter temperatures had been too slight to check the growth of the coffee trees. There are often three flowerings instead of one, or at all events two. It seemed on the whole probable that growth was over-estimated, and that, consequently, when the drought came, the plants were unable to support it. There was a minute immature black fungus, which might be referred to *Depazea*, on the twigs. Prof. Thiselton Dyer read a letter addressed to Dr. Hooker from Dr. Henderson in charge of the Calcutta Botanic Garden, describing the disease of the opium poppy. This appeared to be favoured by moist weather, and the plants affected were infested with *Peronospora arborescens*, and also with a fungus (which Mr. Berkeley identified as *Macrosporium cheiranthi*, a peculiar form of *Cladosporium herbarum*.) The places attacked were black, and the disease progressed from below, upwards. If the plant has not flowered when attacked, it never does so; but if it is on the point of flowering. the sepals, petals, and stamens, do not drop off as they would do in healthy plants. The effect of guano, even in very small quantities, was remarkable in increasing the crop.

Institution of Civil Engineers, April 29.—Mr. T. Hawksley, president, in the chair.—"On the Rigi Railway," by Dr. William Pole, F.R.S., M. Inst. C.E. The object of this railway was to convey passengers to the top of the Rigi, a mountain near Lucerne, from which there was a view so celebrated as to attract large numbers of visitors in the summer months. The line commenced at Vitznau, on the Lake of Lucerne, and was about four miles long. The works are mostly formed by cutting and benching on the rocky slope of the mountain. There was but one short tunnel, and only one iron bridge over a ravine. The gauge was 4 feet 8½ inches.

Glasgow

Geological Society, April 10.—Mr. John Young, vice-president, in the chair.—The chairman exhibited a specimen

of carboniferous limestone from Braidwood, near Carluke, containing in great abundance the tests or shells of a species of Foraminifer, *Saccimina carteri*. Similar organisms had been found in a limestone from the Elf Hills, Northumberland, and described by Dr. H. B. Brady in 1871. They had also been found once or twice in the limestones of the east of Scotland, but so far as he was aware, this was the first instance in which it had been recognised in the limestones of the Lanarkshire coal field.—Mr. J. Thompson, F.G.S., read a paper which he had prepared in conjunction with Mr. Henry Caunter, on the geology of the neighbourhood of Stornoway, island of Lewis. The authors briefly described the relations of the gneissic or Laurentian rocks to the Cambrian strata of the island. The junction of the two formations is seen in the bed of a small stream that flows into the sea in the harbour of Stornoway; also in Garabost Bay, about seven miles to the east. The Laurentians dip N.W., while the lower members of the Cambrian dip at an angle of 23° to the N.E. These beds have been termed by Sir R. Murchison, Upper Cambrian. The authors next described the more recent deposits of the island, beginning with the boulder drift, with its transported striated erratics, all of which belong to the Laurentian system, and are traceable to the west and north-west. They then referred to the gravels and drift-sand which overlie the remains of an extensive bed of peat seen in Stornoway Bay, where it attains a depth of 15 feet. At the lower extremity of this bed, and only seen at extreme low tides, are numerous stumps of trees of considerable dimensions, the roots of which rest upon and pass down through a bed of clay which forms the subsoil. From this it would seem that there has been an extensive subsidence of the island at a comparatively recent period, and that the climatal conditions must have been very different during the time when such trees grew from those which prevail at the present day.

Paris

Academy of Sciences, April 28.—M. de Quatrefages, president, in the chair.—The following papers were read.—On the actions produced in capillary spaces by molecular attractions, by M. Becquerel. The author described the various results produced by inserting solutions contained in cracked vessels into other vessels containing solutions capable of producing precipitates in them, *e.g.* baric nitrate and potassic sulphate. After a few days the solutions communicate by the crack and electric currents are started.—On the heat disengaged by the reactions between the alkalis and water: potassic and sodic hydrates by M. Berthelot. The results obtained lead the author to suppose that there is a potassic hydrate intermediate between the ordinary fused and crystallised hydrates.—On the combinations produced by the electric discharge between marsh gas and carbonic anhydride, and between carbonic oxide and hydrogen, by MM. P. and A. Thenard.—On certain particular spectroscopic observations by Father A. Secchi.—On the application of the pandynamometer to the measurement of the work performed by a steam engine, by M. G. A. Hirn.—On the application of the mathematical theory of elasticity to the study of articulated systems formed by elastic rods, by M. Maurice Levy.—On the composition of the thermic mineral waters of Vichy, Bourbon l'Archambault, and Neris, as regards those substances which invariably exist in water in minute proportions, by M. de Gouvernain.—An examination of the difference produced in the spectrum of chlorophyll by different solvents, by M. J. Chautard.—On the unwholesome nature of the Versailles water supply, by M. E. Decaisne.—On the awakening of the Phylloxera in the month of April 1873, by M. Faucon.—On nebulæ discovered and observed at the Marseilles observatory, by M. E. Stephan.—On characteristics in the theory of conics, on planes, and in space, and on second order surfaces, by M. Halphen.—On the vapour emitted at the same temperature by the same body in two states, by M. J. Moutier.—On the spectrum of erbia, by M. Lecocq de Boisbaudran. The author has found that erbia and erbic phosphate give, when heated, different band spectra, of which the author exhibited plates and tables. These spectra he has carefully investigated, and finding it impossible to attribute either of them to another body, he concluded that they were both due to erbium in different states of combination.—Observations on M. du Moncel's late note on the history of the silent discharge, by M. Arn. Thenard.—On the Manufacture of ammonic sulphate from nitrogenous waste products, by M. L'Hote.—On the conditions of formation of extra silicious pig in blast furnaces, by M. S. Jordan. Experiments on the effects of dynamite, by MM. Roux and Jarrou.—On necrobiosis and gangrene, an experimental study on the phenomena of mortification and putrefaction as they occur in the living body, by M. Chauveau.—On the geology of Mount Léberon, by M. A. Gaudry.

DIARY

THURSDAY, May 8.

Royal Society, at 8.30.—Contributions to the Study of the Errant Annelides of the older Palæozoic Rocks: Prof. Alleyne Nicholson.—Researches in Spectrum Analysis in Connection with the Spectrum of the Sun: J. Norman Lockyer.—The Action of Light on the Electrical Resistance of Selenium: Lieut. Sale.

Mathematical Society, at 8.—On Bicursal Curves, and Plan of a Curve-tracing Apparatus: Prof. Cayley.—On an application of the Theory of Unicursal Curves: M. Hermite.

Society of Antiquaries, at 8.30.

Royal Institution, at 3.—Light: Prof. Tyndall.

FRIDAY, May 9.

Royal Institution, at 3.—A Fortnight in Asia Minor: Mr. Grant Duff, M.P.

Astronomical Society, at 8.

Quekett Club, at 8.

SATURDAY, May 10.

Royal Institution, at 3.—Ozone: Prof. Odling.

MONDAY, May 12.

Royal Geographical Society, at 8.30.

London Institution, at 4.—Elementary Botany: Prof. Bentley.

TUESDAY, May 13.

Royal Institution, at 3.—Roman History and Architecture: J. H. Parker.

Photographic Society, at 8.—On instantaneous Landscape Photography: F. R. Elwell.—Improvements in Carbon Printing: A. Marion.

WEDNESDAY, May 14.

Society of Arts, at 8.—Improvements in Rifles: Capt. O'Hea.

Geological Society, at 8.—Notes on Structure in the Chalk of the Yorkshire Wolds: J. R. Mortimer.—On the genus *Palæocoryne*, Duncan and Jenkins, and its affinities: Prof. P. Martin Duncan.—On *Platysiagum sclerocephalum* and *Palæospinax priscus*, Egerton: Sir Philip de M. Grey-Egerton.—On a new genus of Silurian Asteridæ: Dr. Thomas Wright.

Archæological Association, at 8.—Anniversary.

London Institution, at 7.—Paper and Discussion.

Society of Telegraph Engineers, at 7.30.—On the Block System of Working Railways: W. H. Preece and Capt. Mallock.

THURSDAY, May 15.

Royal Society, at 8.30.

Society of Antiquaries, at 8.30.

Chemical Society, at 8.—On Isomerism: Dr. H. E. Armstrong.

Numismatic Society, at 7.

Royal Institution, at 3.—Light: Prof. Tyndall.

BOOKS RECEIVED

English.—Comet's Tails no longer a Mystery: T. A. R. (Reeves and Son).—Manual for Medical Officers of Health: E. Smith (Knight & Co.).—Manchester Science Lectures, 1871–73. 3rd Series: J. Heywood & Co.—Tropical World. New Edition: Dr. G. Hartwig (Longmans).—The Life of von Humboldt, Vols. i. and ii.: Bruhns, translated by Lassell (Longmans).—Astronomical Plates from the Observatory of Harvard College (Trübner).—Text-books of Science: Electricity, and Magnetism: F. Jenkin (Longmans).—Critiques and Addresses: Thomas Huxley (Macmillan & Co.)—The Familiar History of British Fishes: Frank Buckland (published by the Society for promoting Christian Knowledge).—The Cruise of the *Curacoa* among the South Sea Islands, 1865: J. C. Brenchley (Longmans).

Foreign.—Zeitschrift fur Biologie, Part 1, Vol. ix.—Zoologische Botanische Gesellschaft in Wien, Vol. xxii., 1872.—Die Naturkräfte, Munich. Edited by Dr. K. A. Zittel.

THURSDAY, MAY 15, 1873

A VOICE FROM CAMBRIDGE
II.

THE questions raised by the Cambridge Memorial to which we referred last week are so important that no excuse is necessary for recurring to them. In the first place it may be remarked that the answer of Mr. Gladstone to the Cambridge memorialists, is quite such as any reasonable man might have looked for. University reform is not at present a political question in the vulgar sense of that word. The heart of the masses is not stirred by proposals concerning the tenure of fellowships. The religious element, or rather the sectarian element, has now been largely eliminated from the matter; there remains scarcely anything at stake save the interests of learning and science; and these, as we know, are things of very little value in the eyes of the present Government.

The more one looks at the matter the more it is difficult to see what good the Cambridge Reformers expected to result from their respectable document. No fault can be found with the propositions of the memorial so far as they go. They are just such sound steady-going sober proposals as would naturally come from a body of quiet moderate officials who, on the whole, content with the general state of things, desired to see some practical amendments introduced, but dreaded to agitate, had a wholesome fear of radical changes, and above all, were not clear about the broad features of the necessities which have to be met, or of the changes which have to be brought about.

Until the public mind, to say nothing of the University mind, has gained some clear definite notions about the functions of a University, all attempts at reform must be partial or complete failures.

The prevalent theories concerning the office of a University may be put in three categories.

The first regards the University as an ecclesiastical nursery. This was the original view, but now-a-days is passing out of mind, though tenaciously clung to by some resident members at either University. It only needs to be mentioned to be dismissed.

The second looks upon Oxford and Cambridge as places where the young Tartars of modern English society are covered with a varnish of "culture," and polished into gentlemen. Dr. Lyon Playfair said in the House the other day that the Scotch University taught a man how to make a thousand a year, the English University how to spend it; and in saying this he simply put into forcible language the ideas which are prevalent among many members of the Universities. They distinctly and emphatically discard the idea that it is the duty of the University to equip a man for the struggle for a livelihood, to train him for business, for the arts, for the professions. Their token is "culture," not culture in the sense of higher learning, but in the sense of personal varnish, in the sense of a mental equipment which does not pay, and which is of no use to the owner in practical life, which is a luxury and not a need, a sort of evening dress of the mind, which may be ornamental under the artificial lights of society, but is ill suited for every-day work. Now this sort of culture is not much sought after; for by hard-headed fathers whose sons have to get or to keep their living by their own exertions, it is sought for less and less year by year. The advocates of the view we are dealing with see this very clearly, and accordingly they contend, very logically, that since the world does not care greatly for this kind of culture, and will not send its sons to a University for that only, some other inducements must be provided. And these are found in the prize fellowships, more especially in the non-resident fellowships. A lad of parts whose friends would not send him to Oxford simply to gain that liberal education, "which softens the character and prevents its being strong," goes there because by show of possessing that culture which he despises or even hates, he gains a good round sum of money which it is worth his while to waste three or four years in getting.

The third view, which at present has but few advocates, teaches that the University is a place where anyone and everyone may be trained for any and every respectable path of life, and where at the same time all the interests of higher learning and science are cared for. The advocates of this view say, Do not bribe men by fellowships to come to a University from which they will go carrying with them a very little learning, and that for the most part useless, and an artificial culture of doubtful value. Make it worth their while to come to the University, teach them there what they want to be taught, train them there as they desire to be trained, and there will be no need to bribe them with fellowships. They will then come to Oxford and to Cambridge as they are now going to Owens College, to London, to Newcastle, and to Germany. Take care at the same time that the teaching be not narrow and professional, broaden it with the diligent nurture of higher learning and science, and then there will be every hope of seeing true culture and useful education going hand in hand. Let the youth of the University have the opportunity of seeing the master-minds of the age at their work, so that they may be inspired by them to the highest reaches of thought.

It appears to us that many of those who signed the Cambridge memorial had no clear ideas as to which of the above views they adhered; and hence the uncertain sound of their trumpet. Apparently the document was so loose that supporters of all three views signed it conscientiously; no wonder it fell without effect.

It is unnecessary for us to say that the third view we have mentioned is one which we ourselves support. The real difficulty lies in this, how to change the old Universities to suit these new views, how to ring out the old ecclesiasticism and false culture and ring in useful training with high science and deep active learning and research. The difficulty of this task cannot be exaggerated. Long years of misrule have left suckers of jobbery, like bindweed in an old garden, which come up refreshed with every stirring of the soil. There is a mass of powerful conservatism which has to be striven against. There is a careless public and a still more careless Government which has to be roused. There are plenty of difficulties in the way. If the memorialists really have the reform of the old universities at heart, they will cease to memorialise feebly a feeble administration, and search dili-

gently for some broad scheme of reform which may be introduced without danger, which will render all fellowships unnecessary, which will at once provide for the professional student and the original investigator, and that in such a way that an ignorant Parliament shall have no excuse for tampering with it. And if they do this quickly, they may do it before the Association for Academical Organisation has begun to stretch its limbs.

LONGMANS' TEXT-BOOKS OF SCIENCE

Electricity and Magnetism. By Fleeming Jenkin, F.R.SS. L. and E., M.I.C.E., Professor of Engineering in the University of Edinburgh. (London: Longmans and Co., 1873.)

THE author of this text-book tells us with great truth that at the present time there are two sciences of electricity—one that of the lecture-room and the popular treatise; the other that of the testing-office and the engineer's specification. The first deals with sparks and shocks which are seen and felt, the other with currents and resistances to be measured and calculated. The popularity of the one science depends on human curiosity; the diffusion of the other is a result of the demand for electricians as telegraph engineers.

The text-book before us, which is the work of an engineer eminent in telegraphy, is designed to teach the practical science of electricity and magnetism, by setting before the student as early as possible the measurable quantities of the science, and giving him complete instructions for actually measuring them.

"The difference between the electricity of the schools and of the testing office has been mainly brought about by the absolute necessity in practice for definite measurement. The lecturer is content to say, under such and such circumstances, a current flows or a resistance is increased. The practical electrician must know how much resistance, or he knows nothing; the difference is analogous to that between quantitative and qualitative analysis."

It is not without great effort that a science can pass out of one stage of its existence into another. To abandon one hypothesis in order to embrace another is comparatively easy, but to surrender our belief in a mysterious agent, making itself visible in brilliant experiments, and probably capable of accounting for whatever cannot be otherwise explained; and to accept the notion of electricity as a measurable commodity, which may be supplied at a potential of so many Volts at so much a Farad, is a transformation not to be effected without a pang.

It is true that in the last century Henry Cavendish led the way in the science of electrical measurement, and Coulomb invented experimental methods of great precision. But these were men whose scientific ardour far surpassed that of ordinary mortals, and for a long time their results remained dormant on the shelves of libraries. Then came Poisson and the mathematicians, who raised the science of electricity to a height of analytical splendour, where it was even more inaccessible than before to the uninitiated.

And now that electrical knowledge has acquired a commercial value, and must be supplied to the telegraphic world in whatever form it can be obtained, we are perhaps in some danger of forgetting the debt we owe to those mathematicians who, from the mass of their uninterpretable symbolical expressions, picked out such terms as "potential," "electromotive force" and "capacity," representing qualities which we now know to be capable of direct measurement, and which we are beginning to be able to explain to persons not trained in high mathematics.

Prof. Jenkin has, we think, made great progress in the important work of reducing the cardinal conceptions of electromagnetism to their most intelligible form, and presenting them to the student in their true connection.

The distinction between free electricity and latent, bound, combined, or dissimulated electricity, which occurs so frequently, especially in continental works on electricity, is not, so far as we can see, even alluded to in these pages; so that the student who takes Prof. Jenkin as his sole guide will not have his mind infected with a set of notions which did much harm in their day. On the other hand, terms which are really scientific—the use of which has led to a clearer understanding of the subject—are carefully defined and rendered familiar by well-chosen illustrations.

Thus we find that men of the most profound scientific acquirements were labouring forty years ago to discover the relation between the nature of a wire and the strength of the current induced in it. By the introduction of the term "electromotive force" to denote that which produces or tends to produce a current, the phenomena can now be explained to the mere beginner by saying that the electromotive force is determined by the alterations of the state of the circuit in the field, and is independent of the nature of the wire, while the current produced is measured by the electromotive force divided by the resistance of the circuit. To impress on the mind of the student terms which lead him in the right track, and to keep out of his sight those which have only led our predecessors, if not ourselves, astray, is an aim which Prof. Jenkin seems to have kept always in view.

To the critical student of text-books in general, there may appear to be a certain want of order and method in the first part of this treatise, the different facts being all thrown into the student's mind at once, to be defined and arranged in the chapters which follow. But when we consider the multiplicity of the connexions among the parts of electrical science, and the supreme importance of never losing sight of electrical science as a whole, while engaged in the study of each of its branches, we shall see that this little book, though it may appear at first a mighty maze, is not without a plan, and though it may be difficult to determine in which chapter we are to look for any particular statement, we have an excellent index at the end to which we may refer.

The descriptions of scientific and telegraphic instruments have all the completeness and more than the conciseness which we should look for from a practical engineer, and in a small compass contain a great deal not to be found in other books. The preface contains an outline of the whole subject, traced in a style so vigorous, that we feel convinced that the author could, with a little pains bestowed here and there, increase the force of his reasoning by several "Volts," and at the same time diminish by

an "Ohm" or two the apparent stiffness of some of the paragraphs, so as to render the book more suitable to the capacities of the "Microfarads" of the present day.

ZOOLOGICAL MYTHOLOGY

Zoological Mythology; or, the Legends of Animals. By Angelo De Gubernatis, Professor of Sanskrit and Comparative Literature in the Istituto di Studii Superiori e di Perfezionamento at Florence. 2 vols. (London: Trübner and Co., 1872.)

THE claims which these volumes make to our consideration as students of Nature is that their stories of birds, beasts, and fishes are treated as being Natural History, not indeed in an ordinary, but in an extraordinary sense. It is asserted that they are descriptions in mythical language of the great phenomena of the earth and sky. To no small extent this assertion is indisputably true. In ancient poetry or story, it often happens that the teller of a myth incidentally lets us know what his underlying meaning is. Thus many a passage from the Veda shows that the minds of that poetic race of herdsmen, the ancient Aryans, were so moulded to the dominant ideas of the pasture and the stall, that they saw throughout all heaven and earth the analogues of their beloved herds. The winds chasing the clouds seem, to their fancy, bulls rushing among the cows. The sky is a beneficent cow, giving rain for milk. Indra, the Heaven-god, is a bull of bulls, whose horns are the thunderbolts, who smites in storm the mountain cavern where the cloud-cows are imprisoned, and sets them free. The sun may be fancied a herdsman, as in this ancient Vedic riddle: "I have seen a shepherd who never set down his foot, and yet went and disappeared on the roads; and who, taking the same and yet different roads, goes round and round amidst the worlds." Horses, too, as we moderns know by the classic chariot of the sun, figure in mythic astronomy. Prof. De Gubernatis gives us the beautiful little Russian nature-tale of the maiden Basiliça, who, on her way to the old witch's house, sees a black horseman all in black on a black horse, and then night falls; then she sees a white horseman on a white horse, and day dawns; then a red horseman on a red horse, and the sun rises. The story has been told already in England, but deserves telling again for its absolute certainty of meaning, which hardly requires the old witch's explanation that the black, white, and red horsemen are mythic personifications of night, day, and sun. If, then, we meet with stories very like unquestionable nature-myths, there is a strong case for the mythologists who say these stories are also nature-myths, whose original meaning has been forgotten, so that they have fallen into the state of mere fanciful tales. Thus, in an Esthonian story quoted by our author, this same notion appears of the three horsemen who are personifications of the great periods of light and darkness. The hero comes to deliver the princess from the glass mountain where she sleeps, and he comes dressed first in bronze colour on a bronze-coloured horse, next in silver on a silver-coloured horse, and lastly in golden garb on a golden horse. This certainly looks like a story suggested by the victorious noonday sun coming at last with glowing rays to accomplish the task he had failed to perform in darkness or twilight, to deliver the Spring from the icy fortress of Winter, or, as our nursery tale has it, to awaken the Sleeping Beauty in the Palace where the spell of Winter has bound her and hers in numbness and silence. *Valeat quantum.*

The scientific study of mythology will be advanced by the collection of mythic episodes made with extraordinary earning by Prof. De Gubernatis. It is a museum of material, and a good many of the author's rationalisations of old legends seem plausible. For instance, he adds new versions to the group of tales (to which belong "Tom Thumb" and "Little Red Ridinghood") in which the night is dramatised as a wolf or other monster, which swallows and afterwards releases the hero who represents the sun or day. He goes on to interpret in the same way the stories where the hero is shut up in the sack or chest and cast into the water, but comes safe to land after all, as the sun, shrouded in the shades of evening, crosses the ocean and reappears at morning. The value of such interpretations as these depends, of course, on careful comparison of evidence. Unhappily, however, the general method of the book is unscientific. The author has no strict logic in him. His argument is substantially this: natural phenomena often suggest to tale-tellers or poets ideas which they shape into cock-and-bull stories; therefore, the way to interpret cock-and-bull stories in general is to guess at some natural phenomena which may have suggested them. The consequence of such a principle of interpretation is a network of tangled guesses, which often only mystify the legends they pretend to explain. The ease with which such a method can be applied, and the worthlessness of its results when it is applied, are shown in the author's treatment of common proverbs. As a rule, proverbs really require no explanation; their origin is intelligible at a glance, as it always was; we feel we might have made them ourselves, if we had been clever enough, and proverb-making had been still in fashion. Not so our author. "The black cow gives white milk" means to him that the night produces the dawn, or the moon, or the Milky Way (we are allowed to take our choice which we like best). "Though the cow's tail waggles, it does not fall," seems to us to require no recondite explanation; but to Prof. De Gubernatis it connects itself with a whole fabric of speculations about the night-monster running after the dawn-cow's tail to clutch it. On the whole, we can hardly better characterise the work before us, in its combination of curious material and absurd argument, than by quoting the following piece of amazing nonsense, ending in a parenthesis with a little fact which will be new to most of our readers, and which shows that modern Italy has so kept up old classic customs, that the proverb "Ab ovo usque ad mala" still explains itself, just as we might now say, "From soup to dessert":—

"The hen of the fable and the fairy tales, which lays golden eggs, is the mythical hen (the earth or the sky) which gives birth every day to the sun. The golden egg is the beginning of life in Orphic and Hindoo cosmogony; by the golden egg the world begins to move, and movement is the principle of good. The golden egg brings forth the luminous, laborious, and beneficent day. Hence it is an excellent augury to begin with the egg, which represents the principle of good, whence the equivocal Latin proverb, 'Ad ovo ad malum,' which signified 'From good to evil,' but which properly meant 'From

the egg to the apple,' the Latins being accustomed to begin their dinners with hard-boiled eggs, and to end them with apples (a custom which is still preserved among numerous Italian families)."

It is clear that a theorist who can thus turn the practical sense of his own dinner-table into mythological nonsense about sky-hens and sun-eggs, is no fit guide to students of Comparative Mythology. But his book will be useful to those who can profit by his learning and ingenuity, without being misled by his fantastic extravagance.

OUR BOOK SHELF

The Year-Book of Facts in Science and Art: exhibiting the most important discoveries and improvements of the past year in mechanics and the useful arts, &c. By John Timbs. (London: Lockwood and Co., 1873.)

WE are glad to notice in Mr. Timbs's annual volume an improvement in some of the points in which last year we called attention to very serious deficiencies. There is a more copious reference to the original authorities, though this is still too frequently withheld, and the statements thus deprived of all scientific value; and the references are in general to more trustworthy sources. There is also a sensible diminution in the number of glaring errors of the press, which have been so conspicuous a feature in earlier volumes. The compilation shows, as does everything from the hand of the same editor, unwearied industry; but with all that a lack of the power of distinguishing the worthless from the really valuable. Many of the paragraphs belong unquestionably to the former category, and it is difficult to see what purpose they serve except that of "padding." On the other hand some really important discoveries or applications of the year are altogether unnoticed. Considerable further improvement will be necessary before "Timbs's Year-book" becomes either an adequate or a trustworthy record of the scientific events of the year. The portrait of Dr. Carpenter given by way of frontispiece is exceedingly good.

Das Leben der Erde. Blicke in ihre Geschichte, nebst Darstellung der wichtigsten und interessantesten Frazen ihres Natur-und Kulturlebens. Ein Volksbuch von A. Hummel. (Leipzig: Verlag von Friedrich Fleischer, 1872).

Physikalische und chemische Unterhaltungen. Ein Volksbuch von Dr. Otto Ule und A. Hummel. (Leipzig: Verlag von Friedrich Fleischer, 1873.)

TILL the publication of Hummel's "Leben der Erde" there were scarcely any popular scientific works published in Germany, which may seem strange, seeing that that country has claimed, probably with justice, the intellectual leadership of the world for many years past. It is possible there is less need for popularising the results of science in Germany than in England and France, seeing that the German system of education is so thorough and comprehensive. Germans also have a greater tendency to go about everything in a systematic way; and this is shown with great force and clearness by Mr. Matthew Arnold to be especially the case in their educational organisation, which discourages the acquirement of knowledge in an irregular and haphazard way. In this country again, as well as in France, "the people" generally make their first acquaintance with subjects in which the German people are grounded when at school, long after they have left school from popular scientific treatises. These two works are constructed on somewhat the same plan as the well-known French works of Flammarion, Guillemin, and Reclus, and appear to us to be well and often eloquently written, and so far as we have been able to test them, are accurate and wonderfully full. In the second the authors aim at giving every-day illustrations of physical and chemical laws, and at showing their practical and economical bearings. They divide it into four sections:—1. General phenomena of motion as applied to solid, liquid, and aeriform bodies. 2. Sound, light, and heat. 3. Magnetic and electric phenomena. 4. Chemical phenomena. Hummel's *Leben der Erde*, we should think, would be the more popular of the two, both from the subjects treated of, the greater picturesqueness of language, and the greater abundance and attractiveness of the illustrations, some of which are very fine, though on the whole, not so well executed as such illustrations generally are in corresponding English and French works. He endeavours to show the relation of the earth to other heavenly bodies, gives its geological history, describes its physical geography, including the phenomena of land, water, and air, and concludes with a very eloquent account of the organic life of the earth. On the whole, both works seem to us very creditable to their authors.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Agassiz and Forbes

THE letter from Mr. Alexander Agassiz, published in last week's NATURE, revives an attack which was made by Agassiz and Desor more than thirty years ago. It was then promptly met. (See Forbes's "Historical Remarks on the first Discovery of the real Structure of Glacial Ice," Edin. New Phil. Journal, 1843.) I possess correspondence which abundantly shows that the scientific world (English and Foreign) was thoroughly satisfied with the answer given by Forbes. Much of this correspondence can, if necessary, be published. But the reply given at the time, and which I am confident will satisfy any unprejudiced person, may be found *in extenso* in Appendix B to the "Life and Letters of James David Forbes" (Macmillan and Co., 1873). No answer was ever attempted by Mr. Agassiz to the paper in question, and the facts it contains could not have been allowed to pass by him unchallenged, had they not been accurately given. Mr. Alexander Agassiz may never have read the original paper. The date of his letter shows that he cannot have seen the reprint in the Life of Forbes.

This impeachment of Forbes's character by Mr. Agassiz (made, I willingly grant, with the best motives, and in ignorance of the details of the case) demands an explanation. I am aware that few would give credence to imputations of dishonesty in Forbes's character; but the matter is also of historical interest, and deserves an historical examination. I will therefore, with your permission, lay before the readers of NATURE next week the facts from which they shall judge whether the assertions in Mr. Agassiz's letter are supported by the evidence, or not.

Blackheath, May 10 GEORGE FORBES

Venomous Caterpillars

IN Mr. A. Murray's paper on venomous caterpillars in NATURE of May 1, I observe that in discussing the distinction between the terms poison and venom, he says in reference to the action of snake poison:—"It is said that you may swallow the venom of the rattlesnake with impunity, and I imagine you may, if it does not get absorbed through the mucous membrane; but Dr. Fayrer's experience, lately published, of the effects of the semi-swallowing, which occurs in extracting the venom from a poisoned wound would rather seem to show that such extremely virulent venom would penetrate the mucous membrane and act as if actually introduced by a wound, his throat having become dangerously ulcerated from sucking the poison from the wound of a man bitten by a cobra."

If Mr. Murray will refer to my investigations on this subject, he will find that snake poison produces the same effect when applied to a mucous membrane, and introduced into the stomach, the eye, the intestine, or applied to the exposed surface of a muscle or peritoneum, though not so rapidly as when injected directly into the vascular system. The idea that it may be swallowed with impunity being quite incorrect. But I must

disclaim (having no title to it) the experience he assigns to me in reference to the dangerously ulcerated throat, never having made myself a martyr to science by so experimenting in *propria persona*. I have no doubt, however, as I have elsewhere stated, that this method of treating a cobra bite would not be devoid of danger to the operator.

As to venomous caterpillars. There is one much dreaded by sportsmen in the Himalayan Terai. It is said to be apt to fall from the trees on to persons passing or resting beneath their branches, and causes great irritation of the parts with which it comes in contact, amounting, I have been told, in some cases to erysipelatous inflammation. It is a moderate-sized, dark-coloured, hairy caterpillar, and known (I believe) in those parts of the Terai where I have been, as the *komla*. I have never seen it, but during my tiger-shooting expeditions into the Terai, it was always one of the probable inconveniences to be looked for in a camp in the tree jungle. I have heard many stories of the painful and irritating effects of contact with this creature, whose hairs are said to cause those results not only by breaking into but by also inoculating some irritating secretion into the skin.

London, May 4 J. FAYRER

I HAVE just read with interest your report of the paper on "Venomous Caterpillars," which appeared in your last. Towards the end of the report Mr. A. Murray refers to a hairy caterpillar which he received from Brazil, and remarks that "if the caterpillars have a special venom, then, as in the nettle, there should be a gland at the base of each hair, which should be hollow." I think I know the caterpillar to which he refers, and if I am right, its hairs are not exactly venomous, but produce a considerable amount of irritation in the skin. When in Brazil in 1859, I collected some of these caterpillars. They are very similar in appearance to the larvæ of the British Arctia, but when their hairs are examined under a microscope, they are found to consist of a series of barbed points, the point of each succeeding barb fitting into the divergence of the preceding barbs; at least, that is my recollection, for I have not examined them since then, and cannot find any specimens to do so now. The caterpillar is called in Maranham, "largata de fogo," that is, "fire caterpillar." After these hairs have afforded their protection to the caterpillar during its life, it carefully removes them from its body and weaves them in its cocoon, so that the pupa is thus as safe from intruders as the larva itself was. When a child, I recollect that Maranham was occasionally visited by great numbers of a particular kind of moth, the dust of whose wings produced a very great irritation on the skin, the least touch of one being sufficient to render you miserable for the rest of the evening. I perfectly remember a drove of these putting a quick termination to a small dance at home, as you may easily conjecture that ladies in evening costume are not well protected against such visitors. When in Maranham in 1859, I heard that these moths had not been seen there for many years. I believe their visits were during the rainy season. Some of the British Bombices, *B. quercus*, for example, and some of other genera, are said to possess irritable hair. But in *B. quercus* the hairs are not barbed, and, not being an entomologist, I can give no information respecting the others. HENRY S. WILSON

Anatomical School, Cambridge, May 5

On some Errors of Statement concerning Organ-pipes in Recent Treatises on Natural Philosophy

THAT our best teachers of science, both in their books and lectures make statements which are erroneous in fact, and inferences which are misleading whenever they touch upon the subject of wind instruments is not a little surprising, considering that intellects so highly trained hold in aversion any approach to inexactness, and the strangeness of it is that the errors arise through an ancient human custom, now supposed obsolete among philosophers, of "speaking without knowledge."

The evidence, if tendered, would fill some few pages of this paper, and if names were appended to the quotations the list would include authors most esteemed and honoured.

To cite two instances among many—and they are from works of unquestioned value and authority, and supposed to bring down sciences to the latest date—in the recently completed translation by Prof. Everett of Prof. Privat-Deschanel's "Natural Philosophy," the following passage occurs in explanation of the organ-pipe:—"The air from the bellows arrives through the conical tube at the lower end, and before entering the main body of the pipe has to pass through a narrow slit, in issuing from which it impinges on the thin end of the wedge placed directly opposite, called the lip. This lip is itself capable of vibrating in unison with any note lying within a wide range, and the note which is actually emitted is determined by the resonance of the column of air in the pipe." In another equally valuable work, the "Physics," by Prof. Ganot, translated by Prof. Atkinson, this description is given respecting the free-reed—"the tongue which vibrates alternately before and behind the aperture, merely grazing the edges as seen in the harmonium, concertina, &c., such a reed is called a free reed." Four professors responsible for statements so perversely at variance with facts that it is not possible either writer can have even attempted to ascertain, still less to demonstrate that the facts are as asserted. Practical experience affirms that the lip of the organ-pipe does not vibrate; press it with your hand or hold it in a vice to deaden the assumed vibration, and you will not alter one iota of the pitch of the sounding note: that the free-reed does not in its vibration "merely graze the frame;" it would be fatal to its proper speech if it did, and its vibrations would be checked in a jarring rattle. The facts are too simple to need argument; all that was required was observation.

When Ganot, describing a metal free reed, affirms as a law that when the force of air is increased the pitch of the reed rises, his statement is inexact, for it depends entirely on the accident of taking up a reed more or less rigid in proportion to scale, whether the experimentalist shall prove his assertion or prove the reverse. In the harmonium, of a set of five octaves of reeds, half will go more or less sharp, and half will go more or less flat, as the force of wind is increased, a fact which, if more generally known, might induce players to mitigate some of the insufferable harshness and jangling inflicted on listeners. That "a sharp edge" is essential to the functions of the flue organ pipe is one of the commonest errors entertained by philosophers, and it forms the groundwork for whole pages of false theory. In treatise after treatise it is stated "the air is driven against the sharp edge," "is split upon the sharp edge, and by concussion caused to proceed intermittingly," "the air strikes the sharp edge," "is divided," "is lacerated," "strikes against the upper lip, and a shock is produced which causes the air to issue in an intermittent manner." Another equally common misstatement, and important because so strongly influencing theory, is that "a closed pipe gives a note an octave in pitch lower than an open pipe of the same length; the length of a closed organ-pipe is one-fourth that of the sonorous wave it produces in the air." Proved facts give different results. At my hand this morning there stood a sounding-pipe perfect in finish, its lip quite blunt, by measurement at the edge half an inch in thickness; and whole ranks of pipes were there in various grades of conformation, showing that the sharp edge was immaterial to the functions of a speaking-pipe. Sometimes the chamfering of the lip is desirable, sometimes not, and the builder decides according to the quality and character of each stop. The art in "voicing" a pipe consists in so directing the stream of air that it shall avoid striking the lip, and shall smoothly glide past without shock or noise, or concussion; you get no tone until it does. Actual experiment will show that a closed pipe gives a note only a major seventh below the note it gives as an open pipe, not an octave below; indeed, in the higher range of pipes it will be a whole tone short of the octave, to sound which the pipe would need to be made considerably longer. As having some significance in connection with this, it may be mentioned that there is in an open pipe, whilst sounding, a centre of equilibrium of pressure; it does not occur, as supposed, at the true half of the length, but somewhat below that division; as evidence, take the Flute Harmonique, when desiring to strike the node, it will always be found below the half. Further, as to length. If the open diapason pipe beside me, giving as fine a tone (CCC) as musician can desire, measures 14 ft. 10 in. in length, and its corresponding sound-wave claims 16 ft. or nearer 17 ft., the wide divergence merits better investigation than it has hitherto received. The experiments of Regnault and Seebeck are highly important to this question, but do not reach the conditions pressing for explanation in a speaking organ-pipe. To attempt to demonstrate the laws of organ-pipes with a tuning-fork is as inconclusive as sending galvanic electricity through a dead body and calling the movement life.

There is little difficulty in understanding how it happens that errors respecting wind instruments arise and are perpetuated. Experimental philosophers are occupied with the weightier matters of science, are rarely musicians or familiar with wind instru-

ments; of the trouble and anxiety their caprices give at home and in the workshop they have no knowledge. The organ-pipe is brought into the lecture-room, it is caused to prove what is wanted, more is not looked for; it comes like a beauty in a ballroom, dressed up to play a part and be amiable and gracious: the practical man knows that organ-pipes are very like human beings, of whom Goethe says, "We do not learn to know people when they come to us; to learn their real peculiarities we must go to them."

April 18 HERMANN SMITH

Rock Inscriptions of Brazil

BEING unable to attend the reading of Mr. Whitfield's paper, at the Anthropological Institute, April 22, the following observations are offered.

The rock inscriptions of Brazil are worthy of attention, because they appear to belong to a vast series, to which Mentone affords a large contribution. The suggestion that in the very earliest epochs tally records existed, lends interest to the investigation. It appears probable that military tallies of the levy of men preceded the registers in the historical period of the tribute of men, arms, and money by provinces, such as we find in Herodotus with regard to Persia.

In reference to the possible general connection of such inscriptions as these with the eastern world, it may be observed that Brazil has participated in at least two great migrations.

The Kiriri and Sabuyah of Bahia are allied by language to the ancient Pygmean or Negrito stock. This race is everywhere very low, and cannot have produced even these inscriptions.

The greater part of Brazil is covered by the Guarani or Tupi (Agua) languages allied to the Agau of the Nile region, the Avkhass of Caucasia, &c. It is worth inquiry whether the Mentone inscriptions may not belong to this epoch.

HYDE CLARKE

Abnormal Coloration in Fish

SEEING Mr. W. S. Kent's letter on this subject in NATURE of the 8th inst., a similar instance was recalled to my memory. About three weeks ago I observed in a fishmonger's shop a plaice, nearly one third of the under side of whose body (at the tail) had the usual colour and orange spots of the upper. In this specimen the spots were more numerous and brilliant than usual. The line of demarcation was irregular, but abrupt. The circumstance struck me because I have seen great numbers of Pleuronectidæ, but never one marked thus. The fishmonger told me that he had never seen a like specimen.

ARTHUR NICOLS

Phosphorescence in Wood

FROM the description given by your correspondent, Richard M. Barrington (vol. vii. p. 464) of phosphorescence in coniferous wood, I should imagine it to be extremely probable that the pieces of Scotch fir in question were infested with the spawn of *Polyporus annosus* Fr., a fungus very common on the Coniferæ. The mycelium of this plant (as well as the perfect fungus) is well known to be at times highly phosphorescent, and in the *Gardener's Chronicle* for September 28, 1872, I have figured the perfect state of it as seen so commonly in a luminous condition in the coal mines of Glamorganshire. In these deep pits the spawn of this fungus ramifies about the old shoreing timber, and is so highly phosphorescent as to be clearly seen from a distance of twenty yards. Many other fungi with their mycelia are known to be at times phosphorescent, as *Polyporus sulfureus* Fr. and *Corticium cæruleum* Fr., both common on decaying wood.

In the *Gardener's Chronicle* for September 21, 1872, the Rev. M. J. Berkeley has published a remarkable case of phosphorescence in logs of larch. Here the most luminous parts were where the mycelium was most developed, and the wood gave out such a blaze of white light that although the pieces were wrapped in five folds of paper, yet the light shone through as if the specimens were exposed. The phosphorescence appears to accompany the decomposition of the wood on which the fungi at the same time prey.

W. G. SMITH

Coincidence of the Spectrum Lines of Iron, Calcium, and Titanium

IN Prof. Young's letter published in NATURE, vol. vii., p. 17, some coincidences of the lines of different substances which "are too many and too close to be all the result of accident" are referred to, those of iron with calcium and titanium being especially cited. Two explanations are offered, first that "the metals operated upon by the observers who first mapped out the spectra were not absolutely pure," and second, that "there is some such similarity between the molecules of the different metals as renders them susceptible of certain synchronous periods of vibration."

If we are driven to this second explanation the received inductions of spectrum analysis and the deductions of celestial chemistry based upon them are shaken at their foundation, for if more than one known terrestrial element can display identical lines in the spectrum, the suggestion that other unknown celestial elements may do the same is freely opened. It is therefore very desirable that the spectroscopist should receive all the aid which the studies of chemical specialists can afford him towards the solution of this problem.

I may venture to speak to the instances quoted by Prof. Young. First as regards calcium and iron. In making analyses of a large number of brands of pig iron I found that they all contained calcium, but in very variable proportions, and endeavoured by observing their properties, and by further examination of finished iron, to learn how the presence of calcium affected the quality of iron, but failed to solve this problem. In the course of these investigations, I found that the finished iron, like the pig, presented considerable variations as regards the quantity of calcium contained in it, *but I never found a sample of iron or steel quite free from some trace of calcium.* As I was operating for the most part on superior qualities of iron which had been submitted to the utmost practicable degree of commercial purification, this experience renders it extremely probable that Prof. Young's first explanation is the correct one, so far as iron and calcium are concerned.

The want of any chemical reagent by which minute traces of titanium can be detected in the presence of large quantities of iron, or of a means of completely separating these metals, places a serious difficulty in the way of directly answering the question whether iron is usually associated with traces of titanium; but there are indirect evidences of its very common existence in ordinary iron. The most decided of these is afforded by the common, almost universal, occurrence of the beautiful copper-coloured crystals of cyano-nitride of titanium in the hearth bottoms of blast-furnaces. In many cases their concretions form large masses, where the ores that have been used are not supposed to be titaniferous.

Metallic iron obtains impurities, not only from its ore, but also from the fuel and flux used in reduction, and besides these from the furnace or crucible in which it has subsequently been fused or raised to its welding point. The difficulty of completely purifying iron is so great that many such coincidences as those referred to may be expected *a priori.*

W. MATTIEU WILLIAMS

Musical Stones

WHEN roaming over the hills and rocks in the neighbourhood of Kendal, which are composed chiefly of mountain limestone, I have often found what we call here "musical stones." They are generally thin flat weather-beaten stones, of different sizes and peculiar shapes, which when struck with a piece of iron or another stone, produce a distinct musical tone, instead of the dull heavy leaden sound of any ordinary stone. The sound of these stones is, in general, very much alike, but I know gentlemen who possess sets of eight stones which are said to produce, when struck, a distinct octave. Being only an amateur geologist, I am unable to account for this fact, and would be glad if any of your numerous readers would take the trouble to explain to me, through the medium of your columns, the peculiar composition of the stone in question, and the distinct qualifications nencessary to form a musical stone.

RICHARD J. NELSON

Acquired Habits in Plants

IN NATURE of May 1, p. 7, which I chance not to have seen till now, Mr. Babbington puts a question on the subject of my climbing specimen of violet which I fear I am not botanist enough to answer.

I described it as a "dog" violet simply because it bore leaves and flowers on the same stem, which in my simplicity I supposed was enough to settle its species. But though the subdivisions of *V. canina* be new to me, a word or two of remark and description may elucidate the required point to other eyes. I would add that the specimen, such as it is, is very much at Mr. Babbington's service should he care to see it. It is still recognisable, no doubt, though it suffered considerably from having no better protection for some hours than a fly-book.

In the first place it was not growing in a moist situation or one to account for luxuriance. Though near the river, it was many feet above the water, and was on the further side of a small high road. In this position it had, as I before mentioned, attained a height of two feet and a half, and the flower which first attracted my eye was almost on a level with my waist. The plant had climbed through the hedge like a vetch or a fumitory. On comparing it with the most robust specimens of *V. canina* which I can find this spring, the following points of resemblance and of divergence present themselves. The stem of mine is channelled in the ordinary way, and the leaves tolerably like in shape though rather more pointed. On the other hand, the leaf-stalks and peduncles are in mine much shorter, the upper leaves being almost senile. The position of the bracts is similar, but instead of the conspicuous stipules of *V. canina*, mine has those parts so small as almost to escape notice. Again, while the stem of *V. canina* does not in my experience branch, the stem of mine has, in two places, thrown off a small branch bearing leaves and flowers. Also there was not, as far as I remember, any trace of any shoot from the root except the one stem, while *V. canina*, as ordinarily found, sends up a greater and a lesser flowering stem and a bunch of leaves besides.

I hope that these particulars will shed more light on the subject than I can myself. J. G.

St. Asaph, May 10

JOHN STUART MILL

[BORN MAY 20, 1806; DIED MAY 8, 1873

THOUGH it has not been the custom among specialists to regard Mr. John Stuart Mill as a scientific man, yet we venture to say that he has not left behind him in this country any man who has done more for the general advancement of science. Before Mr. Mill's time men found their way to great discoveries, and succeeded in proving to each other that what they had discovered was scientific truth. But they could tell each other very little about the method of scientific investigation. Indeed Whately, the then greatest authority in logic, pronounced a theory of induction impossible. Mr. Mill, however, did formulate the canons of induction, and in so doing he lit a lamp which will for ever burn a steady guiding light in the path of the scientific inquirer. And the value of this light need be regarded as none the less even if we consider that its chief service lies in guiding us past the snares and pit-falls of error, and the entrances to those mazes and endless labyrinths of unreality in which so many powerful intellects have toiled and spent their strength for nought; nay, worse than in vain, for their brilliant struggles have fascinated thousands and drawn them from the sober highway of truth, which alone is the road to usefulness—to happiness. The vast and still growing influence that Mr. Mill has exerted in this direction is fully recognised by those who regret it most, because they believe that Truth may be reached by other and nobler paths. We are content to note the fact that among the great men of our day no one has done so much as he, to widen the domain of science and to subdue to its methods all subjects of human interest. Choosing for the field of his more serious labours several of the most difficult subjects of research, those that had most eluded the grasp of the understanding, he has enriched the world with works that will long remain monuments of science. His "Logic" is our text-book of the science of evidence. His "Political Economy" is our text-book of the science of wealth. And if there is a scientific work on politics it is Mr. Mill's "Representative Government." One feature of Mr. Mill's character deserves special notice in this connection. He had the true scientific temper, a disinterested love of truth, in a degree not to be surpassed. If it could be shown that in any particular his teaching was unsound, and none were ever able to do this so well as his own disciples, the men whom he had trained to think, no one was more glad that error had been detected than was Mr. Mill himself. It will be enough to remind our readers of one notable example of this. When Mr. Thornton showed that the universally accepted doctrine of the wage-fund was a huge fallacy, Mr. Mill came forward with alacrity to acknowledge that he in common with all other political economists had fallen into a grave error, and that Mr. Thornton had made a most valuable contribution to economic science. If all scientific men could as completely subordinate their personal vanity to the pursuit of truth, progress would be more rapid than at present. The daily papers have already made the reader familiar with the many-sided richness and beauty of Mr. Mill's character. He was an object of loving admiration to all who had the happiness to enjoy his personal acquaintance. The world, while it mourns his loss, does not, cannot know how great and how good a man has been taken away; and still less does it know how ill it can afford to lose such a man.

MINERS' RULES IN THE SEVENTEENTH CENTURY

ON looking over a packet of old papers I have found some documents, of which I enclose copies, written by a German miner, named Brandshagen, who was employed by my ancestor, Sir Philip Egerton, to superintend the attempt to work copper in the New Red Sandstone strata of Cheshire in the year 1697. As the *rules* for miners of that age afford so strong a contrast to the *unruly* behaviour of that class at the present day, they may perhaps interest some of the readers of NATURE. P. DE M. GREY-EGERTON

Worthy & most honourable Sir,—

Your worship give most humbly thanks for employment meself and my countrymen about your Worship mines, which I have enjoyed now above 4 weekes, & not to be att all further unacquainted unto your Worship, I could not forbeare to give a true & plain account of what I have observed in this time about these mines, as good as my smal understanding in y^e^ English linguage would permit, & if it was in any way acceptable then my wishes & desires where fullfilled. I have this time also endeavored to blow up y^e^ rocks by guns powder, as the best way to kill them, butt in y^e^ first time I found y^e^ elements as aire & water where against my designe, y^e^ last I have conquered, & I hope I shall doe so y^e^ other next time when I have occasion for it. I found also some other smal things which would not so soon agree with my hands, for there are many years past, that I did work under ground with my owne hands, butt all these things are now disceased, onely that I was lately too covetous & would have more rocks blown up then my powder was able to; what other blasts for effect have done, your Worship can be informed of it by Mr. Smith. I shall endeavour all what is in my power to serve your Worship with that understanding I have about mines to which I have employed meself now above 15 year, in spending a great deal of money as well for learning as travelling in many places in Europe where good mines where, to come to any perfection in this art. I have received now my things for examination of y^e^ oare, which I will doe as soon as possibly I can come to it in this desolate place, where nothing in y^e^ world is to be had for any commodities what soever it may be, & whilst we are strangers here, & must buy all things for ready, it is impossible to life of what your Worship has allowed unto us & there-

fore I doubt not your Worship will make a distinction between workmen & workmen, with which I recommend me into your Worship' favour allways remaining

Your Worship most humble Servant,

J. A. BRANDSHAGEN

Bickerton, Sept. y^e 24th, 1697

For the Right Honourable S^r Phillipp Egerton, Knt., these.

Rules for all Workmen in general

One of every Workmen he may be of what sort he will shall come half an hour before y^e duely time & give a certain number of strucks with a hammer on an Iron plate, erected to this purpose, to give a Signe to y^e other workmen to come att work, half an hour after he shall doe so att a second time by an other number of strucks & shall streike no more then y^e duely strucks by forfeiting 2*d.*, he has y^e same signes to give all day when y^e miners shall come out & goe under ground again, & this shall doe one workmen after an other from day to day, & he who has done y^e businesse this day shall remember to his follower that he has to doe y^e same next day, & he that wilfully neglected these remembrance shall be punished together with him that shall doe this businesse next day (if he neglect it) for he himself must be carefull about y^e time & day to doe this, & he that shall give y^e signs too late, has forfeited 6*d.*, & he that shall not doe it att all shall loose all his wages, due to him, & by consent of y^e mines Lords shall be turned of from y^e work.

In y^e morning before y^e last struck is done on y^e Iron plate every workman belonging to y^e mines must appeare to y^e appointed place near y^e work, or he has forfeited 2*d.*, & he that comes half-an-hour after, 2*d.* more, & so following for every half-an-hour 2*d.*, & this is understood of all times when y^e signe is given.

When they are together they may doe a short prayer that God may give his blessing to their work, that it may raise to y^e honour & glory of him, & to y^e benefit & blessinesse of y^e mines Lords & their whole familie.

After this every one must goe to his post, & diligently performe to what y^e steward shall order him, in doing y^e contrary he shall be duely punished, & he who shall leave y^e work within y^e duely hours & before y^e signe is given, shall loose 6*d.* or for every half-an-hour 2*d.* as y^e steward shall think fitt, & he that is found neglectfull shall every time have forfeited 2*d.*

When it is pay-day, every workmen before he gett money must shew to y^e steward his tools & other things what is trusted in his hand by y^e lost of all his wages, & if there should want any of such things, he must leave so much money of his wages as it is worthy in y^e stewards hand, till he restores y^e same.

He that hindered one an other in his work it may be in what way it will, either by ill words, quarreling or in other ways, must duely be punished as y^e steward thinks fitt, because every one must be quiet with his work; have they any thing one against an other, they may bring it before y^e steward, or cleare their things after y^e work is done att an other place.

No body shall be permitted without leave of y^e steward to take any oare away for a shewing piece, or under any other pretext, butt he may y^e same aske from y^e steward & be content with that he gives him, and if any should doe y^e contrary, he is so heigh to punish as y^e steward shall think sufficient.

No body shall bring any person or persons not belonging to y^e mines, either under ground or at any other place where y^e oares or other things are, without permission of y^e steward, & that by y^e penalty ot one shilling.

Every man must be in a Christian-like beheaviour, and he that speekes blasphemes, or gives scandales, or does other things near y^e mines with which God is offended, shall every time be punished with 4*d.* or more according to his crime.

When it is pay-day every one must be of a modest behaviour against ye steward, and must not murmer against him when his wages is decurted for punishement, butt must bring his complaints (if he has any against it) before y^e mines Lord, if neverthelesse that he has gotten his wages, he must not goe from y^e steward away, till y^e whole payment is done, & can give witnesse that every one has received his due.

No workmen shall make more holy days in y^e year besides y^e Sunday, then y^e Lords of y^e mines shall allow them, or shall be punished as one that leaves y^e work for a whole day.

He that turned y^e hour glasse in a wrong way shall loose one shilling.

SUPPRESSION OF SCENT IN PHEASANTS*

THE pheasant, from nesting on the ground, is peculiarly exposed to the attacks of four-footed or ground vermin, and the escape of any of the sitting birds and their eggs from foxes, polecats, hedgehogs, &c., appears at first sight almost impossible. This escape is attributed by many, possibly by the majority, of sportsmen to the alleged fact that in the birds when sitting the scent which is given out by the animal at other times is suppressed; in proof of this statement is adduced the fact that dogs, even those with the keenest powers of smell, will pass within a few feet, or even a less distance, of a sitting pheasant without evincing the slightest cognizance of her proximity, provided she is concealed from sight. By others this circumstance is denied, they reason *à priori* that it is impossible for an animal to suppress the secretions and exhalations natural to it—secretion not being a voluntary act. I believe, however, that the peculiar specific odour of the bird is suppressed during incubation, not, however, as a voluntary act, but in a manner which is capable of being accounted for physiologically. The suppression of the scent during incubation is necessary to the safety of the birds, and essential to the continuance of the species. I believe this suppression is due to what may be termed vicarious secretion. In other words, the odoriferous particles which are usually exhaled by the skin are, during such time as the bird is sitting, excreted into the intestinal canal, most probably into the cæcum or the cloaca. The proof of this is accessible to every one; the excreta of a common fowl or pheasant, when the bird is not sitting, have, when first discharged, no odour akin to the smell of the bird itself. On the other hand, the excreta of a sitting hen have a most remarkable odour of the fowl, but highly intensified. We are all acquainted with this smell as increased by heat during roasting; and practical poultry keepers must have remarked that the excreta discharged by a hen on leaving the nest have an odour totally unlike those discharged at any other time, involuntarily recalling the smell of a roasted fowl, highly and disagreeably intensified. I believe the explanation of the whole matter to be as follows: the suppression of the natural scent is essential to the safety of the bird during incubation; that at such time vicarious secretion of the odoriferous particles takes place into the intestinal canal, so that the bird becomes scentless, and in this manner her safety and that of her eggs is secured. This explanation would probably apply equally to partridges and other birds nesting on the ground.

The absence of scent in the sitting pheasant is most probably the explanation of the fact that foxes and pheasants are capable of being reared in the same preserves; at the same time the keepers are usually desirous of making assurance doubly sure, by scaring the foxes from the neighbourhood of the nests by some strong and offensive substance.

* From Mr. Tegetmeier's forthcoming work on "Pheasants for the Covert and the Aviary."

THE NEW PROFESSOR OF ENGINEERING AT GLASGOW

IT has already been announced in NATURE that the Crown authorities have appointed Prof. James Thomson, C.E., LL.D., to succeed the late Prof. W. J. M. Rankine in the Glasgow Chair of Engineering and Mechanics; and as that gentleman has been deemed worthy to occupy the Chair that was long filled by a man of world-wide eminence, it may not be undesirable to give a brief sketch of his professional and scientific career.

Prof. Thomson is the elder brother of Sir William Thomson, and son of Dr. James Thomson, a former Professor of Mathematics in the University of Glasgow. The early part of his education was obtained in the Royal Belfast Academical Institution, and he completed his studies in Glasgow, where he obtained the degree of M.A. in 1840, with honourable distinction in Mathematics and Natural Philosophy. During the year 1841–42, he was a student in the class of Civil Engineering and Mechanics under Prof. Lewis D. B. Gordon, C.E., Rankine's predecessor, and even then he was distinguished for his accurate mathematical and physical knowledge, and for his ready appreciation of the principles of applied mechanics. He afterwards became an industrious pupil in the Horseley Iron Works and Manufactory, near Tipton, in South Staffordshire, and subsequently he entered the service of Mr. (now Sir) William Fairbairn, in whose workshops on the Isle of Dogs and in Manchester he had the benefit of assisting to execute engineering works of the greatest magnitude, and of great variety. After prosecuting his profession for several years in England and Scotland, he ultimately settled down in Belfast as a civil engineer.

When the Professorship of Civil Engineering in Queen's College, Belfast, became vacant in the year 1857, Mr. Thomson obtained the appointment. He has now occupied that position for a period of fifteen years.

Besides attending to the duties of his class, Prof. Thomson carried on an extensive practice as a consulting engineer, both at home and abroad, chiefly in connection with water supply, irrigation, the drainage of sugar plantations in Demerara and Jamaica, and other swampy lands, and in designing machinery for the same, and in other hydraulic works. One of his earliest inventions was the well-known Vortex Turbine, which affords an admirable example of an unusual combination of great scientific knowledge and practical skill in the same person. This application of mechanical principles is one of the most successful means of turning water power to advantage that has hitherto been placed at the service of the engineering profession. Many examples of the Vortex Wheel are now in successful operation in various parts of the world, and the invention was deemed to be so important that the Privy Council renewed the patent when the ordinary period of fourteen years had expired. Another of his useful inventions is the Jet Pump and Intermittent Reservoir for the drainage of swampy lands.

Among Prof. Thomson's inquiries in the domain of pure physics a prominent place must be given to those which he instituted regarding the lowering of the freezing temperature of water by pressure. This he determined by theoretical considerations entirely, and the result announced by Prof. James Thomson was afterwards exactly confirmed by the experiments instituted by his distinguished brother. The "arrival by theory without the aid of experiment at so extraordinary a physical fact, calls to my mind most forcibly," says Joule, "the discovery of Neptune by Adams and Leverrier, and is one great step towards the position to which we may eventually hope science to attain, when a perfect acquaintance with theoretical principles will enable us to dispense with the appeal to experiment so necessary, in most cases, at the present time." This discovery and its experimental verification immediately suggested a perfect solution of the problem of the descent of glaciers, and it has since led to many kindred discoveries in pure science. Like his predecessor, Prof. Thomson has extensively contributed to the advancement of science through the medium of the British Association. On five separate occasions he has been selected as the Secretary of the Mechanical Section of that body, and he has been a number of times specially deputed to make reports and conduct experimental researches for the solution of questions in practical engineering. The tendency of Prof. Thomson's mind may be, to some extent, judged of by the character of the papers on physical, mathematical, and mechanical subjects which he has published or communicated to various scientific bodies. They are nearly forty in number, and are published in full or abstract in the *Cambridge and Dublin Mathematical Journal*, the *Edinburgh New Philosophical Journal*, the Transactions of the Royal Societies of London and Edinburgh, the Proceedings of the British Association, and the Transactions of the Institution of Engineers in Scotland.

Prof. Thomson's honorary degree of LL.D. was obtained from the University of Glasgow about two years ago. His formal induction by the Senatus of the University took place last month, and his professional duties in his *alma mater* will commence in the ensuing winter session.

JOHN MAYER

THE FERTILISATION OF THE WILD PANSY

AMONG the accurate and acute observations of C. C. Sprengel towards the close of last century,* which have received but scant attention from his successors, even down to our own day, was one on the subject of the colouring of variegated flowers. This botanist, with an insight into the mutual relationships of animal and vegetable life far in advance of his age, suggests that this colouring may serve as a guide to insects in seeking for the honey which serves for their food, and the search for which is so powerful an agent in the conveyance of the pollen, and the consequent fertilisation of the flower. Sprengel pointed out that in almost all variegated flowers the variegation follows a regular pattern, and that when it consists of streaks or stripes, these streaks almost invariably point to the nectary, or the receptacle of the sweet secretions which form the food of insects, in whatever part of the flower it may be situated. With this idea as a starting point, an interesting line of inquiry may be carried out as to the connection between the presence of scent and the absence of variegation in flowers. It will be found as a general rule, though not without exceptions —and it would be very interesting to attempt to trace the reason of these exceptions—that those flowers which possess a powerful odour are (in the native state) self- or whole-coloured, while brilliantly variegated flowers are, as a rule, scentless. On the hypothesis that each of these properties has for its object the attraction to the flower of the insect necessary for the fertilisation of its seeds, it is easy to be seen that the presence of both in the same flower is needless; and hence we find that Nature is in the habit of husbanding her resources, and not supplying needlessly to the same flower two different provisions for securing the same end.

Having had an opportunity during the present spring of observing the structure, with reference to the phenomena of fertilisation, of the flower of the common Wild Pansy (*Viola tricolor* sub-sp. *arvensis* of Hooker's "Student's Flora") I have thought a description of it might be of interest to the readers of NATURE, and especially to anyone who is able to contrast the phenomena in the variegated and scentless pansy with those in the scented and almost whole-coloured sweet violet.

The corolla of the wild pansy consists of five petals

* Das entdeckte Geheimniss der Natur im Bau und in der Befruchtung der Blumen: von Christian Konrad Sprengel. Berlin, 1793.

(Figs. 1, 2), the two upper ones of which, *a*, *b*, have no colouring, the two lateral petals *c*, *d*, have each one conspicuous broad streak, and are furnished near the base with a tuft of hairs; while the lowest, *e*, has a number of streaks, usually either 5 or 7, and is also provided with a tuft of hairs near the base; this petal is prolonged below into a spur. All the streaks, on both the lateral and the lowest petal, point exactly towards the centre of the flower *f*, where are the stamens and pistil. The stamens (Figs. 3, 4, 5) are also five in number; the filaments, *a*, are very short; the anthers, *b*, form a circle surrounding the pistil, closely applied to it, and also closely touching one another at their edges; each anther has the connective, *c*, prolonged above into an orange-coloured appendage; and these also, somewhat overlapping one another, form a complete ring round the pistil. Two of the stamens are prolonged below into remarkable kneed appendages, both of which project down into the spur of the lower petal, partially filling it up. The pistil (Figs. 6, 7) consists of a nearly globular ovary, *a*, an irregularly curved style, *b*, much narrower below, and furnished in front with a remarkable wedge-shaped black line, *c*, and of a single stigma, *d*, hooded in shape, the viscid stigmatic surface of which is contained in a deep cavity near its summit. In the open flower, this stigma (*e*, Fig. 3) has a most grotesque resemblance to a monkey's or old man's face. The anthers open laterally and rather within, for the discharge of the pollen, so that it falls naturally on the lower part

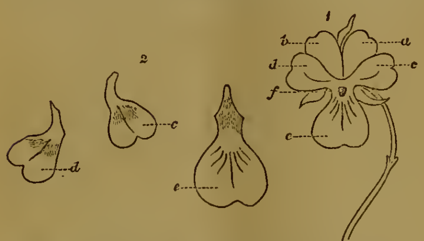

FIG. 1.—1, Flower of *Viola arvensis* *a*, *b*, upper petals; *c*, *d*, lateral petals *e*, lower petal; *f*, centre of flower. 2, The petals separated; *c*, *d*, lateral petals; *e*, lower petal.

of the style, which they completely invest, and it is difficult to see how, without artificial means, any of it will reach the stigma; the flower is also distinctly protandrous, the stigmatic cavity not being fully matured till the flower has been some time open and the pollen fully discharged. The "nectary," or part specially devoted to the secretion of the honey, is the termination of the two appendages of the stamens which project into the spur of the corolla (indicated at *f*, Figs. 3 and 5). When the sweet juice is collected here in sufficient quantities, it drops down into the bottom of the spur, to which all access of rain is prevented by the hairs that fringe the petals around the entrance of the passage to the spur.

With regard to the fertilisation of the violets, which, as has been mentioned, can obviously scarcely take place without foreign aid, Sprengel gives a long and very full description of the manner in which the sweet violet is visited by bees and humble bees, the insertion of whose proboscis into the spur of the corolla, and then its withdrawal, will necessarily remove some of the pollen, and bring it into contact with the stigma either of the same or of a different flower. It seems hence to have been assumed rather than observed that the wild pansy is fertilised in the same manner; although Sprengel states that he has not usually seen this species visited by bees, and Müller's observations* are by no means decided. My own view is that the wild pansy is fertilised chiefly, if not entirely, by very minute insects of the Thrips kind. During a long observation one morning this spring of a field in which these flowers were very abundant, I never once saw them visited by a humble-bee or other large species, and the only insect observed to frequent them was a little species of Thrips, and these only in small numbers, which I attribute to the circumstance that my only opportunity was the first warm sunny morning after a long period of cold weather, when but few insects had yet left their winter retreats. Sprengel indeed says that the wild pansy is greatly frequented by Thrips, although he believes the fertilisation to be effected by bees.

If this view be correct, the markings of the flower furnish the insect with a most remarkable series of guide-posts (or, as Sprengel terms it, "Saftmaal") to the nectar which serves as its food. The streakings on the lateral and lower petals form a sure guide, as soon as the little visitor reaches the flower, all converging (as shown in Fig. 1) to the centre of the flower and summit of the ring formed by the connectives of the anthers. Here even a minute Thrips can with difficulty force its way between the style and the closely adjacent ring of anthers, the deep orange tips of which would naturally attract it; but here it meets with a most curious and valuable assistance

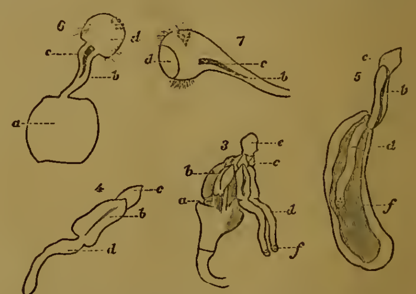

FIG. 2.—3, Pistil and stamens; *a*, filaments; *b*, anthers; *c*, connectives; *d*, appendages to lower stamens; *e*, stigma; *f*, honey-glands. 4, Lower stamen (enlarged); *b*, anther; *c*, connective; *d*, appendage 5, The same, seen within the spur of the corolla 6, Pistil; *a*, ovary; *b*, style; *c*, wedge-shaped streak; *d*, stigma. 7, The same, seen laterally at a later stage.

in the wedge-shaped streak on the front side of the style (as seen at *c* in Figs. 6 and 7), the broad upper end of which is distinctly visible above the anther-ring, tapering downwards to a sharp point near the bottom of the style, where the insect would be at once landed on the upper part of the kneed appendages, along which it has now simply to descend until it reaches the nectar, the object of its journey. The style is much narrower towards the base than above, and hence there is room for a considerable accumulation of pollen here, as it escapes from the anthers. The insect must necessarily carry away a considerable quantity of the pollen in its descent and ascent of the style; whether for the purpose of pollenising the stigma of the same or of a different flower is not at first sight clear. The heteracmy of the flower (*i.e.* the male and female organs being mature at different periods) favours the idea of cross-fertilisation, which may very well happen from the active little Thrips visiting many flowers in the course of a day. The ovules of the wild pansy are indeed abundantly fertilised, much more generally, in fact, than those of the sweet violet, the mature capsules of which frequently result from the unopened, self-fertilised, "cleistogenous" flowers, which have not, as far as I am aware, been observed in the pansy.

ALFRED W. BENNETT

NOTES FROM THE "CHALLENGER"*

II.

ON Sunday, March 2, we saw the first patches of gulf-weed drifting past the ship, and flying-fish were abundant. Our position at noon was lat. 22° 30′ N., long. 42° 6′ W., Sombrero Island distant 1,224 miles. At night the phosphorescence of the sea was particularly brilliant, the surface scintillating with bright flashes from the small crustaceans, while large cylinders and globes of lambent light, proceeding probably from *Pyrosoma* and some of the Medusæ, glowed out and slowly disappeared in the wake of the vessel at a depth of a few feet.

The next morning we sounded at 7 A.M. in 2,025 fathoms with No. 1 line, the "Hydra" machine and 3 cwt., a slip water-bottle, and one thermometer; a stop-cock water-bottle was bent on at 925 fathoms from the bottom. The corrected bottom temperature was 1°·9 C, the temperature of the surface being 22°·8 C. During the morning the naturalists were out in a boat with the towing-net, and they brought back a number of fine examples of *Porpita*, several of *Glaucus atlanticus*, some shells of *Spirula* bearing groups of small stalked cirripeds, and many large radiolarians. One of the Spirula shells was covered with a beautiful stalked infusorian.

We proceeded in the evening under all plain sail. The soundings on the chart in advance of us seemed to indicate an extensive rise, with a depth of water averaging not much more than 1,700 fathoms, and it was determined to dredge again on the following day.

On the morning of March 4 we sounded in lat. 21° 38′ N., long. 44° 39′ W., in 1,900 fathoms, with No. 1 line, the "Hydra" and 3 cwt., the slip water-drop, and a thermometer. The bottom was grey ooze, as on the day before, and the bottom temperature 1°·9 C. The dredge was put over at 8 A.M. It was intended to attach a "Hydra" tube with disengaging weight a little below the bottom of the dredge; the weight slipped, however, close to the surface, and the dredge was lowered in the ordinary way with $1\frac{1}{2}$ cwt. 500 fathoms in advance. The dredge came up about 4 o'clock with a small quantity of ooze containing some red clay, a large proportion of calcareous débris, and many foraminifera, chiefly *Orbulina* and *Rotalia*.

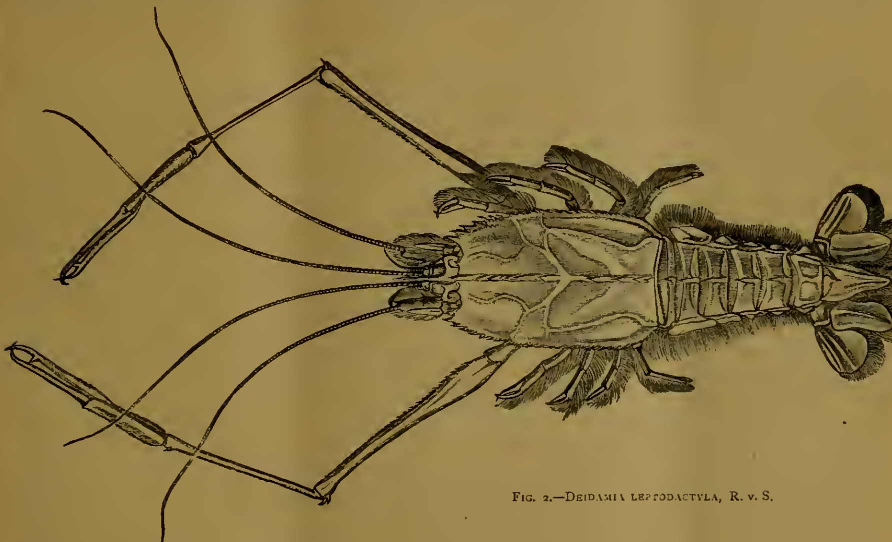

FIG. 2.—DEIDAMIA LEPTODACTYLA, R. v. S.

Warped in the hempen tangle there was a fine specimen of a handsome decapod crustacean, having all the principal characters of the family Astacidæ, but differing from all the typical decapods in the total absence of eye-stalks and eyes. Dr. v. Willemoes-Suhm has given this interesting deep-sea form such a preliminary examination as is possible in the absence of books of reference. I quote from his notes. *Deidamia leptodactyla*, n.g. and sp. (Fig. 2). The specimen, which is a male, is 120 mm. in total length and 33 mm. in width across the base of the cephalo-thorax, which is 60 mm. in length. Three rows of spines, one in the middle line and one on each side, run along the cephalo-thorax, which is divided by a transverse sulcus into an anterior and a posterior part, the former occupied by a central gastric and lateral hepatic regions, and the latter by a central cardiac and latent bronchial regions. The abdomen, which consists as usual of seven segments, has the central series of spines of the cephalo-thorax continued along the middle line. The sixth segment bears the caudal appendages, and in the seventh, the telson, we find the excretory opening. The lateral borders of the body, and all the appendages with the exception of the first pair of ambulatory legs, are edged with a close and very beautiful fringe of a whitish-yellow colour.

There are two pairs, the normal number, of antennæ, then come mandibles, then maxillæ; three pairs of maxillipeds, five pairs of ambulatory legs, and five pairs of swimmerets. As most of the appendages differ from those usually met with in the Astacidæ only in detail, I need here only mention that the anterior antennæ have two pairs of flagella, one of which is very long, longer than the external flagellum of the external pair.

The form of the first pair of ambulatory legs is singularly elegant. They are 155 mm. in length—considerably longer than the body; they are very slender, and end in a pair of very slender denticulated chelæ, with a close,

* Continued from p. 30.

velvet-like line of hairs along their inner edges. The rest of the ambulatory legs are much shorter, and all bear chelæ, a character which will demand a certain relaxation of the diagnosis of the Astacidæ if *Deidamia* is to be placed in that family.

The specimen captured being a male, the first pair of swimmerets are somewhat modified. The four other pairs of swimmerets, which are 33 mm. in length, bear each two narrow swimming processes richly fringed with hair, and a short flagellum.

The absence of eyes in many deep-sea animals and their full development in others is very remarkable. I have mentioned ("The Depths of the Sea," p. 176), the case of one of the stalk-eyed crustaceans, *Ethusa granulata*, in which well-developed eyes are present in examples from shallow water. In deeper water, from 110 to 370 fathoms, eye-stalks are present, but the animal is apparently blind, the eyes being replaced by rounded calcareous terminations to the stalks. In examples from 500 to 700 fathoms in another locality, the eye-stalks have lost their special character, have become fixed, and their terminations combine into a strong pointed rostrum. In this case we have a gradual modification, depending apparently upon the gradual diminution and final disappearance of solar light. On the other hand, *Munida*, from equal depths, has its eyes unusually developed and apparently of great delicacy. Is it possible that in certain cases, as the sun's light diminishes, the power of vision becomes more acute, while at length the eye becomes susceptible of the stimulus of the fainter light of phosphorescence? The absence of eyes is not unknown among the Astacidæ. *Astacus pellucidus*, from the Mammoth Cave, is blind, and from the same cause—the absence of light; but morphologically the eyes are not entirely wanting, for two small abortive eye-stalks still remain in the position in which eyes are developed in all normal decapods. In *Deidamia* no trace whatever remains either of the eyes of sight or of their pedicels.

On Thursday the 6th we sounded in 2,325 fathoms, sending down a thermometer and the slip water-bottle. The temperature registered was 1°·7 C., and the specific gravity of the sample of water was 1·02470 at 21° C., that of the surface water being 1·02556, at 23°·3 C.

A good deal of gulf-weed drifted past during the day, and a boat was sent out to collect some. About half a dozen closely twined bundles were procured, and on examining them it was found that the bundle was bound together by strings of the viscid secretion of *Antennarius marmoratus*, and formed a nest containing the eggs of the fish. Several young examples of this grotesque little animal have been from time to time brought in among the gulf-weed; also many crustaceans, several of the nudibranchiate mollusca characteristic of the gulf-weed fauna, such as *Scillæa pelagica* p., and many planarians.

The dredge came up at 4.15 P.M. with a small quantity of red mud, in which we detected only one single but perfectly fresh valve of a small lamelli-branchiate mollusk. In the mud there were also some sharks' teeth of at least two genera, and a number of very peculiar black oval bodies about an inch long, with the surface irregularly reticulated, and within; the reticulates closely and symmetrically granulated the whole appearance singularly like that of the phosphatic concretions which are so abundant in the greensand and trias. My first impression was that both the teeth and the concretions were drifted fossils, but on handing over a portion of one of the latter to Mr. Buchanan for examination, he found that it consisted of almost pure peroxide of manganese.

The character both of the exterior and interior of the nodule strongly recalled the black base of the coral which we dredged in 1,530 fathoms on the 18th of February; and on going into the matter, Mr. Buchanan found not only that the base of the coral retaining its external organic form had the composition of a lump of pyrolusite, but that the glossy black film covering the stem and branches of the coral gave also the reaction of manganese. There seemed to be little doubt that it was a case of slow substitution, for the mass of peroxide of manganese forming the root showed on fracture in some places the concentric layers and intimate structure of the original coral. The coral, where it was unaltered, had the ordinary composition, consisting chiefly of calcic carbonate. Whether the nodules dredged on March 7th are pieces of rolled coral, the ornament on their surface being due to an imperfect crystallisation of the surface layer of the peroxide of manganese, or whether they form another case of pseudomorphy, the peroxide of manganese replacing some other organism, we have not the means of determining. The whole question is a very singular one.

Some of our party, using the towing-net and collecting gulf-weed on the surface from a boat, brought in a number of things beautiful in their form and brilliancy of colouring, and many of them strangely interesting for the way in which their glassy transparency exposed the working of the most subtle parts of their internal machinery; and these gave employment to the microscopists in the dearth of returns from the dredge. Our position was now lat. 19° 57′ N., long. 53° 26′; Sombrero distant 558 miles.

Sunday was a lovely day. The breeze had fallen off somewhat, and the force was now only from 2 to 3. The sky and sea were gloriously blue, with here and there a soft grey tress on the sky, and a gleaming white curl on the sea. A pretty little Spanish brigantine, bright with green paint and white sails, and the merry, dusky faces of three or four Spanish girls, came in the morning within speaking distance and got her longitude. She had been passing and repassing us for a couple of days, wondering doubtless at the irrelevancy of our movements, shortening sail, and stopping every now and then in mid ocean with a fine breeze in our favour. On Monday morning we parted from our gay little companion. We stopped again to dredge, and she got far before us, and we saw with some regret first her green hull and then her white sails pass down over the edge of the world.

The sounding on Monday the 10th gave 2,675 fathoms, with a bottom of the same red clay with very little calcareous matter. The bottom temperature was 1°·6 C., that of the surface being 23°·3 C. We had been struck for some time past with the singular absence of the higher forms of life. Not a bird was to be seen from morning to night. A few kittiwakes (*Larus tridactylus*) followed the ship for the first few days after we left Teneriffe, but even these had disappeared. A single petrel (*Thalassidroma pelagica*) was seen one day from one of the boats on a towing-net excursion, but we had not seen one of the southern sea-birds. For the last day or two some of the larger sea-mammals and fishes had been visible. A large grampus (*Orca gladiator*) had been moving round the ship and apparently keeping up with it. Some sharks hung about, seeking what they might devour, but we had not yet succeeded in catching any of them. Lovely dolphins (*Coryphæna hippurus*) passed in their varying irridescent colouring from the shadow of the ship into the sunshine, and glided about like living patches of rainbow. Flying-fish became more abundant, evidently falling a prey to the dolphins, which are readily deceived by a rude imitation of one of them, a white spinning bait, when the ship is going rapidly through the water.

On Tuesday the 11th we pursued our course during the forenoon at the rate of from six to seven knots, with a light breeze, force 3 to 4. The dredge-line was veered to over 4,000 fathoms, nearly 5 statute miles. The dredge came up at about half-past five o'clock, full of red mud of the same character as that brought up by the sounding machine. Entangled about the mouth of the dredge and embedded in the mud were many long cases of a tube-

building annelid, evidently formed out of the gritty matter which occurs, though sparingly, in the clay. The tubes with their contents were handed over to Dr. v. Willemoes-Suhm, who found the worms to belong to the family Ammocharidæ (Claparède and Malmgren), closely allied to the Maldania or Clymenidæ, all of which build tubes of sand or mud. The largest specimens dredged are 120 mm. in length by 2 mm. in width. The head is rounded, with a lateral mouth. There is no trace of cephalic branchiæ. The segments are not divided from one another; but the *tori uncinigeri*, which are occupied by the hair-like setæ, and the elevations bearing small *uncini*, indicate the beginning of a new segment.

There is no doubt that this annelid is closely allied to the genus *Owenia*, but it differs from it in the absence of cephalic branchiæ. Malmgren, has, however, already proposed the name of *Myriochele* for a form in which this absence of branchiæ occurs. The description of the northern form on which Malmgren's genus is founded is not at hand, so that it is impossible in the meantime to determine whether the two forms are identical or specifically distinct.

As bearing upon some of the most important of the broad questions which it is our great object to solve, I do not see that any capture which we could have made could have been more important and more conclusive than that of this annelid. The depth was 2,975, practically 3,000, fathoms—a depth which does not appear to be greatly exceeded in any part of the ocean. The nature of the bottom, which consists of a smooth red clay with a few scattered sand grains and a very small number of foraminifera shells, was very unfavourable to higher animal life, and yet this creature, which is closely related to the Clymenidæ, a well-known shallow-water group of high organisation, is abundant and fully developed. It is fortunate in possessing such attributes as to make it impossible even to suppose that it may have been taken during the passage of the dredge to the surface, or have entered the dredge-bag in any other illegitimate way; and its physiognomy and habits are the same as those of allied forms from moderate depths. It affords, in fact, conclusive proof that the conditions of the bottom of the sea to all depths are not only such as to admit of the existence of animal life, but are such as to allow of the unlimited extension of the distribution of animals high in the zoological series, and closely in relation with the characteristic faunæ of shallower zones.

On Thursday the 13th our position at noon was lat. 18° 54′ N., long. 61° 28′ W.

On the forenoon of the 14th we were still 35 miles from land, and we sounded in 1,420 fathoms. The bottom had altered greatly in character: it now consisted chiefly of calcareous foraminifera of many species, mixed with a considerable portion of the broken spicules of siliceous sponges. The bottom temperature registered was 3° C. The water-bottle was accidentally broken in taking in, so that that observation was lost. As we were now within sight of land, and all our results were evidently modified by its immediate proximity, we regarded our first deep-sea section as completed. WYVILLE THOMSON

A MODERN STERNBERGIA

AT a time when botanists of some repute are not ashamed to confess their inability to deduce satisfactory characters for the determination of plants from their internal anatomy, old workers in this field may well turn back to refresh their memories on such points, and to inquire whether their eyes may not have deceived them in the investigations of former years when microscopes were not what they now are. In doing this a few days ago in connection with the examination of a carboniferous conifer, I was surprised to find that I had overlooked or omitted to note the fact that the Balsam Fir of Canada (*Abies balsamea*), which affords the well-known Canada-balsam, has that curious structure of pith well known in Palæozoic Conifers, and which has been named *Sternbergia*. It is well seen in young twigs one or two years old, and though on a smaller scale, is very similar to that of *Dadoxylon materiarium* of the upper coal-formation of Nova Scotia and Prince Edward Island, as I have figured this in my recent report on the geology of the latter province.

This modern Sternbergia is not produced by the mere breaking of the cellular tissue transversely by elongation of the fibre; but, as I pointed out many years ago in the case of the coal-formation Sternbergiæ,* is a true organic partitioning of the pith by diaphragms of denser cells opposite the nodes, as in *Cecropia pellata*, and some species of *Ficus*, &c. The pith of the Balsam Fir is, like that of many other conifers, composed of dotted or transversely marked cells elongated vertically, and reminding one of the pseudo-vascular pith of some Lepidodendroid trees. The transverse diaphragms are composed of denser cells flattened horizontally, and they are, as in Sternbergia, accompanied by constrictions of the medullary cylinder. As in some fossil conifers, the diaphragms are not perfectly continuous.

The plan of growth of the modern fir does not permit its pith to increase in diameter. This was different in the Palæozoic conifers, in which the Sternbergia pith is sometimes nearly two inches in diameter.

In Palæozoic, as in modern times, Sternbergia piths were not confined to one family of trees. Corda has shown this structure in *Lomatophloios*, which is equivalent to *Lepidophloios* or *Ulodendron*. I have shown that it exists in several species of Lepidodendroid and Sigillaroid trees and in *Leptophleum*.† Williamson, who first established it in the Conifers, has also found it in *Dictyoxylon*. Still I have nowhere found these remarkable fossils so abundant as in the upper coal-formation, and either in the interior of calcified or silicified trunks of pine or with fragments of wood attached to them sufficient to indicate their coniferous character.

I may add, that the microscopic structure of young twigs of modern conifers presents many interesting points for comparison with fossil trees, and that in making longitudinal slices of the pith of recent specimens, care should be taken not to be misled by the mere crumpling of the cellular tissue sometimes caused by the pressure of the knife. J. W. DAWSON

* Canadian Naturalist and Geologist, 1857.
† Journal of the Geological Society, May 1871.

NOTES

PROFESSOR CARUS, the well-known naturalist of Leipsic University, who is to fill Professor Wyville Thomson's chair during the absence of the latter with the *Challenger*, commenced his duties on May 2 last, by an able and eloquent address on the study of zoology. He is fully convinced that "the final form of our (zoological) system will be a pedigree."

THE *Challenger* arrived at Halifax on May 9, all well. She had a successful passage from Bermuda, the dredgings and soundings being very satisfactory. On the 18th inst. she will leave this port on a return voyage to Bermuda.

WITH great regret we record the death of Mr. John Stuart Mill, at the age of 67 years, on May 8, at Avignon, from a sudden attack of erysipelas, which cut him off in four days. He has been buried beside his wife at Avignon. A meeting of the friends of Mr. Mill has been convened, at Willis's Rooms, for Tuesday, 20th inst., to consider in what manner the national respect for his memory may be most fittingly testified.

A COMMITTEE for the erection of a monument to Liebig has been constituted at Munich. Councillor von Niethammer is the chairman, Prof. Von Bischoff the vice-chairman, and Professors

Vollhard and Von Jolly are the secretaries. The King of Bavaria has subscribed 1,000 florins.

THE purchase for the National collection, by the Trustees of the British Museum, of Mr. A. R. Wallace's splendid collection of birds from the Malay Archipelago, will be gratifying to all who are interested in science. Mr. Wallace being so thoroughly acquainted with ornithology, and having obtained so many of the specimens himself from localities recorded by himself at the time, makes the collection much more valuable than the skins alone would have been, if they had been accumulated by a less thorough master of the subject. That such is the case, is proved by the great value of Mr. Wallace's paper on the Parrots of the Malay Archipelago, which appeared in the Proceedings of the Zoological Society, nearly ten years ago; and another on the Pigeons of the same region, published in the *Ibis*, at about the same time. It is also not to be forgotten, that the discovery of one of the most important of recent points in physical geography, namely, the situation of the line which separates Asia from Australasia, in other words, *Wallace's line*, was made in great measure from the observations by the author,—whose name is thus deservedly immortalised,—of the differences in the avifaunas of Bali and Lombock.

THOSE of our readers who are interested in University science teaching will be glad to learn that Dr. Michael Foster's course of Elementary Biology at Cambridge, which commenced last week, is attended by more than 30 students. This unexpectedly large attendance has taxed to the utmost the space at disposal. However, such arrangements have been made as will enable every student to have a fair though not large amount of space at his disposal, each set of reagents, &c., being used in common by two or three men. Nothing could illustrate more strongly the urgent need for further provision of working-room for biological students at Cambridge; as scarcely any space is now available for advanced histological, embryological, or physiological research. Dr. Foster's course this term is very similar to that given to science teachers in the summer at South Kensington, and is the first that has been held in term-time at Cambridge, a few students having gone through a like course last long vacation. It is probable that there may be a still larger attendance at future courses of this kind, as Dr. Foster announced that he should require students to have received this or similar teaching before admission to the winter courses of practical physiology. Dr. Foster is assisted in the work of practical demonstration by Mr. H. N. Martin, D.Sc., M.B. of Christ's College, Mr. C. Yule, B.A. of St. John's College, and Mr. T. W. Bridge, of Trinity College, the newly-appointed Demonstrator of Comparative Anatomy.

MR. JOHN ARROWSMITH, the well-known geographer, died on May 2, at the age of eighty-three years.

A GENTLEMAN writes us that he was invited by the Royal Commissioners to act as a juror at the Vienna Exhibition, but was at the same time coolly told that our Philistian Government had placed no funds at the disposal of the Commissioners wherewith to defray the necessary expenses of those who are willing to devote their valuable time and experience to the service of their country. Our readers will not be surprised at this. Other Governments have discovered that even in the most commercial, as well as in the highest light, the encouragement of science "pays." The British Government, with five millions on the right side of their account, still regard science as a beggarly Lazarus, to whom, for mere shame's sake, they are compelled to throw an occasional crumb. As our correspondent says, poor little Switzerland has devoted two and a half times the pittance our Government have allowed to defray the expenses of the Vienna Commission; while the amount expended by Austria in their department of former exhibitions was at least four times as much as we have devoted to theirs.

CAPT. F. J. OWEN EVANS, R.N., F.R.S. Chief Naval Assistant in the Hydrographic Department of the Admiralty, and in charge of the Magnetic Department, has been appointed Companion of the Most Honourable Order of the Bath.

THE publication of the eighth volume of the *Zoological Record* which, as we announced some time since, has been so long delayed through the unfortunate indisposition of one of the contributors may now be shortly expected. The ninth volume containing the zoological literature of 1872 is now in hand, the recorders being the same as in the eighth volume, with the exception of Prof. Traquair, whose place is supplied by Prof. Lütken of Copenhagen. The Editor will be glad to receive separate copies of papers published in journals (especially those which have not a very wide circulation) addressed to the care of the publisher, Mr. Van Voorst, 1, Paternoster Row, London. Such separate copies, however, to be of use, should have the original pagination indicated.

THE Society of Antiquaries of Scotland has just come into the enjoyment of an estate in Caithness, of which the reversionary interest was bequeathed to it for the purpose of founding a Lectureship of Archæology.

MR. BESSEMER intends to found a gold medal, to be given annually to any member of the Iron and Steel Institute who may have displayed literary capacity, or promoted the progress of metallurgical science by original research.

PROFESSOR NEWCOMB'S "New Tables of the Motions of Uranus," are announced as already in the press, and may be expected to be published during the approaching summer. They have been prepared and will be printed at the expense of the Smithsonian Institution. Prof. Newcomb has already, by using all known observations of Neptune, compiled the very accurate tables for computing the motions of that planet that have been used in the "American Nautical Almanac." Having thus provided for the most distant member of our system, he has now returned to Uranus, and finds that his present tables (which will complete the survey of the solar system) represent quite completely the hitherto inexplicable movements of that body.

THE Cincinnati Observatory, founded by Prof. Mitchell, is, we learn, to be removed, and established in a manner worthy of the wealth of Cincinnati. From the drawings it may be judged that the dome of the new building will be thirty-five feet in diameter in the inside. The new site was highly approved of by Prof. Abbe, who continued until lately to be the director of the observatory at Cincinnati, and was presented by John Kilgour, Esq., who also added thereto the sum of ten thousand dollars to provide for the new building.

AMONG the resolutions adopted by Congress at its last session was one authorising the President to invite the International Statistical Congress to hold its next, or ninth, session in the United States. The invitation is to be formal and cordial, and it is provided that should this be accepted the President is authorised to appoint the usual organisation commission, and to take the other preliminary and necessary steps for the meeting of this body, and for holding its session at such time as may be deemed expedient by the Statistical Congress.

A TELEGRAM announces that some of the crew of the Arctic exploring ship *Polaris*, which left New York under the command of Captain Hall in 1871, have been landed in Newfoundland. They were picked up in an open boat 40 miles from the coast of Labrador. It seems, by their statements, that in August 1872, the ship, being beset with ice, commenced landing provisions.

Suddenly the ice broke, and the men who were upon it were carried away. They drifted southward for 196 days—more than six months—and the ice, which originally was five miles in circumference, was gradually reduced to a few feet. They then took to the only remaining boat. Captain Hall, they report, died of apoplexy in November 1871. These statements have been received with distrust.

MR. LAMONT's beautiful steam yacht *Diana*, which has been chartered by Mr. Benjamin Smith, of London, for a voyage of exploration in the Northern Seas, left Dundee on Saturday. The yacht is manned by a crew of twenty, and although there is a sailing master, Mr. Smith will have complete control. The first point of rendezvous will be Cobbe's Bay, on the north-west of Spitzbergen, where Mr. Smith expects to meet his own sailing yacht, the *Samson*, which was despatched from Hull with stores on May 1 under the command of Captain Walker, for many years connected with the Dundee whaling fleet. Every effort will subsequently be made to push as far northward as possible. During the voyage marine and land plants will be gathered and observations of the tides and currents made. The *Diana* is provisioned for a year, but the object contemplated is expected to be realised in about six months.

AT the recent meeting of the Delegates of the French Learned Societies, gold medals were awarded to the following:—M. Leymerie, for his geological studies in the Pyrenees; M. Bleicher, military surgeon, for his interesting geological observations on the central plateau of France and the environs of Montpelier; M. Guillier, for his researches on the geology and industrial products of the department of Sarthe; M. Pomel, for his investigations on the geology of the Sahara; M. Sirodot, for his work on the algæ (*Lemanea*), which grow in fresh running water. Silver medals were awarded to M. Cauvet for various observations on vegetable anatomy and physiology; to M. Verlot, for his catalogue of the vascular plants of Dauphiny; M. Gassies, for his investigations on the terrestrial and river shells of New Caledonia; to M. Villot, for his observations on the curious metamorphoses and strange migrations of certain worms found in wells and in standing water.

IN 1859, an attempt was made to start a Zoological Garden in Philadelphia, which fell to the ground during the subsequent war. A fresh company is now being formed to carry out the original intention, though on a larger scale. A site has been secured in Fairmount Park, and capital is to be obtained in the following manner:—Certificates of stock are to be issued of not less than fifty dollars each. All receipts derived from the Gardens and collections of the Society, are to be applied annually—first, to the maintenance of the establishment; secondly, to the payment of six per cent. on the stock; and third, any balance remaining to go to the gradual extention of the collection of the Society and the improvement of its grounds. Many influential citizens are supporting the project.

THE Annual Report of the Visitors of the Royal Institution shows a considerable increase in the number of members, and is otherwise very satisfactory.

THE Rev. Thomas Fowler, M.A., Fellow, Sub-Rector, and Tutor of Lincoln College, has been elected to the Professorship of Logic at Oxford, vacant by the death of Prof. Wall.

MR. HYDE CLARKE will on Tuesday, the 20th instant, read a paper at the Anthropological Institute, on "The Egyptian Colony and Language in the Caucasus."

THE Royal Cornwall Polytechnic Society, has published its list of prizes for 1873. The largest sums, varying from ten guineas to one guinea, are offered for improvements in mine ventilation, mining, boring machinery, and similar departments. Small premiums are offered for essays, local observations, and collections of Natural History, especially such as illustrate the Natural History of the county.

WE have received the "Report on the Condition of the Sea Fisheries of the South Coast of New England in 1871-2," by Prof. S. F. Baird. As the result of a thorough investigation, Prof. Baird comes to the conclusion that during the last few years there has been a decided decrease in the number of food-fishes in these waters: the decrease being mainly due to the combined action of the fish-ponds or weirs and the blue-fish, the former destroying a large percentage of the spawning fish before they have deposited their eggs, and the latter devouring immense numbers of young fish after they have passed the ordinary perils of immaturity.

FROM the "Report of the Commissioners of Fisheries of the State of New York," we learn that the rivers of that State are being plentifully stocked with useful fish, especially shad; and the Commissioners are confident that the people of the United States will in a short time rely upon restocking their waters, and not upon game laws, to keep up a full supply of fish for their markets.

WE have received the first two parts of Mr. Tegetmeier's magnificent work on "Pheasants for the Covert and the Aviary." We shall notice it fully when completed.

THE much-vexed question as to whether seals are fish or not, as regards the oil to be obtained from them, has recently come up in a practical shape between the governments of the United States and Newfoundland. The fishery treaty lately entered into between the United States and Great Britain, and about to go into actual operation in the course of the present summer, provides that *fish* oil shall be admitted free, but that other oils shall pay a duty of ten per cent. This question is one that would be very easy of solution if it were purely zoological in its character, since, as every one does or should know, the seal and porpoise, as well as the whale, are warm-blooded mammalia, having nothing in common with the fish any more than has the man who, for the time being, goes into the water for the purpose of bathing. It appears, however, to be the general practice with commercial nations to class all oils obtained from marine objects, whether cetaceans, birds, or fishes, as fish oil, and on this ground it is probable that the claim of the Newfoundland authorities to have seals recognised as fish will be accepted.

THE following additions to the Brighton Aquarium have been made during the past week:—Two young Seals (*Phoca vitulina*) from Jan-Mayen Island, Arctic Sea, presented by Mr. John Clark; two Porpoises (*Phocæna communis*), from Rye Bay, purchased; one Angler (*Lophius piscatorius*), from Cornwall; Bass (*Labrax lupus*); Gurnards (*Trigla lineata*); Grey Mullet (*Mugil capito*); Conger-eels (*Conger vulgaris*); Sand Smelts (*Atherina Presbyter*); Pollack Whiting (*Gadus pollachius*); Rocklings (*Motella mustela*); Sand Launce (*Ammodytes lancea*); one Octopus (*Octopus vulgaris*), from the French coast; two cuttle-fish (*Sepia officinalis*); Prawns (*Palæmon serratus*); Foliaceous Coralline (*Eschara foliacea*); Anemones, numerous.

THE additions to the Zoological Society's Gardens during the past week include a Chinese Water Deer (*Hydropotes inermis*), from China, presented by Mr. R. Swinhoe; four Peafowl (*Pavo cristatus*), from India, presented by Mrs. Stern; two Koodoos (*Strepsiceros kudu*), and a Pluto Monkey (*Cercopithecus pluto*), from Africa; a Weeper Capuchin (*Cebus capucinus*), from South America, deposited; three Cole Tits (*Parus ater*), from the British Isles; four Spix's Cavies (*Cavia spixii*), from Brazil; a tawny Eagle (*Aquila nævioides*), from Africa, purchased; a Markhoor (*Capra megaceros*); five Peacock Pheasants (*Polyplectron chinquis*); and five Chilian Pintails (*Dafila spinicauda*), born in the Gardens.

THE BIRTH OF CHEMISTRY

X.

The Theory of Phlogiston—Comparison with Hooke's Theory of Combustion.—Early Ideas regarding Calcination.—Stephen Hales—His Pneumatic Experiments.—Boerhaave.—Conclusion.

ABOUT the year 1669 we find the first dawnings of a theory which was proposed in order to connect together various chemical phenomena, and notably for the explanation of combustion, the common and most obvious of all chemical actions. This theory, known as the "Theory of Phlogiston," powerfully influenced chemistry for a century; indeed upon its ruins the structure of modern chemistry was raised by the labours of Lavoisier, Priestley, and Scheele. The proposers of this theory —John Joachim Becher (b. 1625, d. 1682) and George Ernest Stahl (b. 1660, d. 1734) endeavoured to trace the cause of various phenomena of chemical change to the assimilation or rejection of what they called "*materia aut principium ignis, non ipse ignis*"—not actual fire, but the principle of fire; a something not much unlike the pure, elemental, celestial fire which a few ancient and many Middle Age writers had feigned to exist. Stahl believed this *materia ignis* to be a very subtle, invisible, substance, which neither burns nor glows; its particles penetrate the most dense substances, and are agitated by a very rapid motion. When a body is burned it loses phlogiston; when a body is un-burned, if we may use such an expression, or de-oxidised, it assimilates phlogiston (φλογιστὸς, burnt). Thus if lead is heated for some length of time it is converted into a powdery substance which they called *calx of lead*, and we, *lead oxide*; the lead has lost Phlogiston, said Stahl. On the other hand, if this same calx of lead is heated with red-hot charcoal, it is deoxidised and becomes lead again. It has now assimilated the Phlogiston, which it had before lost.

But here arose a difficulty. A metal was found to be heavier after calcination than before; thus loss of Phlogiston lead to gain of weight, which was altogether anomalous, and apparently incapable of explanation. But the Phlogistians were equal to the occasion; the supporters of a pet theory will create any number of the most vague and impossible hypotheses, rather than yield up their darling to destruction: so, said they, Phlogiston is a principle of levity; it confers negative weight; it makes bodies lighter, just as bladders attached to a swimmer lighten him.

The theory was applied as generally as possible:—thus sulphuric acid is produced by burning sulphur under certain conditions of oxidation; the sulphur loses Phlogiston, and becomes heavier like the metallic calx; hence sulphuric acid is sulphur *minus* Phlogiston, while sulphur is consequently sulphuric acid *plus* Phlogiston. In fact *loss of phlogiston* was synonymous with what we call *oxidation*; and *gain of phlogiston* with *deoxidation*. The existence of Phlogiston was so utterly unsupported by experimental proof that the theory could scarcely exist without many opponents. The endurance of the most false chimerical theory is often really wonderful. The Phlogistians were attacked first in one direction, then in another, yet the theory continued to find supporters. At last, as a last resource, hydrogen gas—recently investigated by Cavendish—was said to be Phlogiston, but this was so entirely different from the Phlogiston of Stahl that the theory was now seen on all sides to be fast giving way. At length Lavoisier, a century ago, conclusively disproved the theory by means which cannot be discussed here, because they belong to the more advanced history of the science.

How the crude, unscientific, illogical theory of Phlogiston could have arisen in the face of Hooke's admirable theory of combustion, and Mayow's experiments in support of it, must always remain a mystery. It is probable that if Mayow had not died a young man, or if Hooke had found leisure to prosecute his views, the theory of Phlogiston would never have been propounded. The theory has been much over-praised. The only service which it rendered to the science was that it introduced a certain amount of order and system, which was hitherto wanting. It led to the grouping together of certain classes of facts, and, to a slight extent, to the application of similar modes of reasoning to similar chemical phenomena. And although that reasoning was altogether wrong, it seemed to indicate the means by which, with a more perfect and advanced system, chemistry might become an exact science subject to definite modes of treatment.

We have more than once spoken of calcination, which was indeed one of the most prominent operations of old chemistry. Since the examination of the process led to the proposal of just ideas concerning the materiality of the air—most often denied by ancient and middle-age writers—it may be well to glance at the early ideas regarding calcination. Here then was the dominant experiment in this direction: I take a bright lustrous metal, tin or lead, melt it, keep it in a molten state for awhile, and it is converted into powder, which weighs more than the original metal. Again I heat this same powder with charcoal, and it becomes metal again; yet nothing that can be seen has been added to the metal, or taken away from its calx. Geber defines calcination as "the pulverisation of a thing by fire, by depriving it of the humidity which consolidates its parts." He observed that the metal increases in weight during the operation, although "deprived of its humidity." Cardanus asserted that the increase of weight in the case of lead amounted to one-thirteenth the weight of the metal calcined; and he accounted for it on the supposition that all things possess a certain kind of life, a *celestial heat*, which is destroyed during calcination; hence they become heavier for the same reason that animals are heavier after death, for the celestial heat tends upwards. This idea was almost similar to that of the Phlogistians, although published more than a century before Becher wrote his *Physica Subterranea*. In

FIG. 22.

FIG. 22.—Measurement of the elastic force of the gas produced by fermenting peas.

1629 Jean Rey, a physician of Bergerac, attempted to discover the cause of increase, and attributed it to the absorption of "thickened air" (*l'air espessi*) by the metal during calcination. Lemery, as we have seen, attributed the gain to the absorption of *corpuscules de feu*. Afterwards came the nitre-air of Mayow, then a century later the increase was proved to be due to the union of the body with a constituent of the air which Lavoisier named oxygen gas; and this gas was first discovered by heating one of the calces (calx of mercury), about which so much speculation had been wasted, and so little experiment bestowed, by earlier writers.

We are drawing towards the end of our subject, but we think any account of the earlier history of chemistry would be very incomplete without a notice of the work of Dr. Stephen Hales (born 1677, died 1761). In a number of papers communicated to the Royal Society, and afterwards published in a work entitled *Statical Essays*, we find a variety of experiments by Hales, chiefly relating to pneumatic chemistry. Herein we find an account of "a specimen of an attempt to analyse the air by a great variety of chymico-statical experiments, which show in how great a proportion air is wrought into the composition of animal, vegetable, and mineral substances, and withal how readily it resumes its former elastick state, when in the dissolution of those

substances it is disengaged from them." In order to determine the quantity of air disengaged from any substance during distillation or fusion, Hales placed the substance in a retort, and luted the retort to a large receiver with a small hole, at the bottom; water was caused to occupy a known space in the receiver, and the amount of air expelled was estimated by noting the amount of water remaining in the receiver at the conclusion of the experiment, after cooling. Hales employed the following apparatus (Fig. 21) to measure the volume of air generated by any kind of fermentation, also by the reaction of one body upon another.

The substances undergoing fermentation were placed in *b*, and over the whole a vessel, *a y*, was inverted, closed below by the vessel *x x*, and containing above a certain amount of air, to the level *y*. If air were generated, the water in *a* sank (say to *y*); while if air were absorbed by the bodies in *b*, the water rose (say to *n*). Sometimes he placed different substances on pedestals in a jar of air, and ignited them, as Mayow had done, by a burning-glass, and noted the alteration in the bulk of air. He did this with phosphorus, brown paper dipped in nitre, sulphur, and other substances. If he required to act upon substances by means of a strong acid, he would place the substance in a

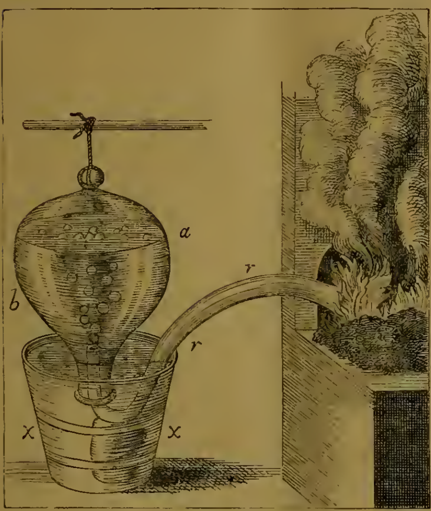

FIG. 23 —Hales' pneumatic experiments.

suitable vessel on a pedestal in a known volume of air, standing over water, and would suspend over it a phial which could be emptied by pulling a string. These devices were closely copied by Priestley and Lavoisier in their experiments upon gaseous bodies. If a substance required to be heated violently, it was placed in a bent gun-barrel, *r r* (Fig. 23), one end of which was placed in a furnace, while the other was placed under a bell jar, *a b*, full of water, inserted in the pail of water *x x*. He distilled a number of substances, apparently taken at random, and determined the amount of gas evolved, but he appears to have been at no pains to determine the nature of the gas, assuming it to be ordinary atmospheric air. Thus he distilled 1 cubic inch of lard, and collected thirty-three cubic inches of gas as the products of decomposition. Tallow, horn, sal ammoniac, oyster shells, peas, amber, campbire, and many other substances, were similarly treated.

Two grains of phosphorus ignited in a closed vessel of air, were found to absorb 28 cubic inches of air. 211 grains of nitre mixed with bone-ash yielded 90 cubic inches of gas; 54 cubic inches of water on boiling yielded 1 cubic inch of air. In order to measure the elastic force of the gas produced by fermenting peas, Hales filled a small, strong bottle, *c* (Fig. 22) with peas, filling up the interstices with water; mercury to a depth of half an inch was then poured in, and of course remained at the bottom of the vessel *c*. A long tube, *a z*, the lower end of which dipped beneath the mercury, was securely fastened into the mouth of the bottle *b*, and fixed air-tight. In a few days' time the peas were in a state of fermentation, and the generated gas had forced the mercury to ascend in the tube *a z* to a height of 80 inches, hence the gas in *c* was existing under a pressure of about 35 lbs. on the square inch.

Hales also produced gases by various reactions. Thus he poured a cubic inch of sulphuric acid on half a cubic inch ot iron filings: no effect took place until he had diluted the acid with water, when forty-three cubic inches of *air* (as he calls it—in reality hydrogen gas) came off. Iron filings mixed with nitric acid, or with ammonia, or sulphur, were found to absorb air. A cubic inch of chalk treated with dilute sulphuric acid produced thirty-one cubic inches of *air* (in reality carbonic anhydride gas). If space permitted, we could say much more of Hales' works. His experiments on respiration, and on various principles of vegetation, are exceedingly ingenious, and often accurate. It has often been said that Lavoisier created modern chemistry by the introduction of the balance into chemical experiments, but here we find Hales weighing his substances, and measuring his gases, years before Lavoisier was born. Hales did not sufficiently investigate the nature of the various gases which he produced in the course of his experiments, but he assuredly paved the way for many of the after discoveries of Priestley, Cavendish, and Lavoisier.

Dr. Hermann Boerhaave, of Leyden (b. 1668, d. 1738), was a contemporary of Hales. He was the author of the first comprehensive system of chemistry:—a bulky quarto in two volumes, entitled *Elementa Chemiæ*, which appeared in 1732, and which for many years was the chemical text-book of Europe. In it he defines chemistry as "an art which teaches the manner of performing certain physical operations, whereby bodies cognizable to the senses, or capable of being rendered cognizable, and of being contained in vessels, are so changed by means of proper instruments, as to produce certain determinate effects, and at the same time discover the causes thereof for the service of various arts."

But hold! our task was to give some account of the *birth* of chemistry, while a science with such a ponderous definition as the above, is no longer infantile. The babe has grown up about us until it has assumed a tremendous individuality. The great discoveries of the fathers of modern chemistry, Lavoisier, Scheele, Priestley, Cavendish, Davy, need not be told here; they belong to the later history of chemistry. We have traced the science from its commencement in the crude metallurgical and other operations of the ancients, to the time when a comprehensive system of the science appeared. And when we think of the vast dimensions of the science of to-day, the numberless text-books in every language, the great laboratories springing up in every country, the immense amount of original research, we are carried back in spirit to those mistaken—but often grandly energetic men—who said to the disciples of their art:—

Ora!
Lege, Lege, Lege, Relege, Labora!
Et Invenies.

G. F. RODWELL

SCIENTIFIC SERIALS

Bulletin Mensuel de la Société d'Acclimatation de Paris. The April number contains much interesting information as to the work done by the Society, which besides gratuitously distributing specimens of various useful animals or plants wherever they are likely to thrive, also lends or lets to those persons, whose tastes or knowledge fit them for the charge, some of the rarer species of animal or vegetable life, thus sowing the seeds of miniature *jardins d'acclimatation* throughout the country. During the last 12 months 3 monkeys have been born at the Paris Gardens, one of them in March last. In that month 75 mammalia and 1,669 birds of various sorts were received, while the Society was able to distribute 62 mammalia and 1,731 birds. The Society aims at encouraging the reproduction of all sorts of useful animals, not merely confining its efforts to the maintenance of a stock for exhibition. An interesting account is given of an oyster breeding establishment and aquarium at Biarritz, and of the cultivation of silkworms in France generally. Our French neighbours have set us the example of cultivating

our oysters; we may learn some day to follow in their steps' and turn our attention, so far as our climate will allow of it, to the "education" of silkworms. This art is becoming quite a recognised industry in France, and the success that has attended its adoption is very gratifying. Bamboos, Spanish broom (*Stipa tenacissima*), China grass or China nettles, Californian pines (*Pinus sabiniana*), are among the plants which are referred to as proper to be introduced into France.

SOCIETIES AND ACADEMIES

LONDON

Mathematical Society, May 8.—Dr. Hirst, F.R.S., in the chair. Prof. Cayley communicated an extract from a letter he had received from M. Hermite "On an application of the theory of unicursal curves," and then gave accounts of the two following papers, "Plan of a curve-tracing apparatus," and "On a rational quintic correspondence of two points in a plane:" another paper entitled "Bicursal curves" (*i.e.* curves with a deficiency *one*) by the same gentleman, was taken as read.—Mr. S. Roberts read a short "Note on the Plückerian characteristics of epi- and hypo-trochoids," &c., showing that the curves were unicursal: he gave also the order and class. In connection with these curves Mr. J. L. Glaisher advocated the use of Mr. Perigal's term "bicircloids." Amongst the presents received were twenty-two memoirs, &c., by the late Prof. de Morgan, presented by Mrs. de Morgan.

Geological Society, April 30.—Joseph Prestwich, F.R.S., vice-president, in the chair.—On the Permian Breccias and Boulder-beds of Armagh, by Prof. Edward Hull, F.R.S., Director of the Geological Survey of Ireland. In this paper the author described certain breccias occurring in the vicinity of Armagh, which he referred, both on stratigraphical and physical grounds, to the Lower Permian series, considering them to be identical with the "brockram" of Cumberland, and the Breccias of Worcestershire and Shropshire. The author further referred to the extensive denudation which the Carboniferous beds have undergone in Armagh, and also alluded to the occurrence of beds of Permian age near Benburb, between Armagh and Dungannon.—Geological Notes on Griqualand West, by G. W. Stow. The geological results of a journey made by Mr G. W. Stow and Mr. F. H. S. Orpen from the Orange Free State into Griqualand West are communicated by Mr. Stow in this paper, with numerous carefully executed sections and a geological map based on the survey map prepared by Mr. Orpen for the Government. From the junction of the Riet and Modder Rivers (south of the Panneveldt Diamond-fields) to Kheis and the Schurwe Bergen, the track traversed three degrees of longitude. The return route north-east to Mount Huxley and Daniel's Kuil, and eastward to Likatlong, on the Hart or Kolang River, was nearly as long. From the Modder, first south-westward and then westward, to the junction of the Vaal and Orange, the olive shales of the *Dicynodon-* or Karoo-series, traversed frequently by igneous rocks, form the country, and are seen in some places to lie unconformably on older rocks. The shales reach to the end of the Campbell Randt, on the other side of the Orange River, and have been, it seems, formed of the débris of those old hills to a great extent. The oldest rocks of the locality are seen cropping out here and there in the gorges at the foot of the Randt, and consist of metamorphic rocks, greatly denuded, on which the massive and extensive siliceo-calcareous strata of the Great Campbell Plateau lie unconformably. These latter and the breccias of their slopes are coated thickly with enormous travertine deposits. Igneous rock-masses occur around Ongeluk, west of the Jasper range, and then bright-red jasper rocks crop up near Matsáp, succeeded to the west by the parallel quartzite range of Matsáp, and again by other bedded jaspers, which seem to lie in a synclinal of the quartzite rocks, which come up again in the Langeberg. These are succeeded by lower rocks, consisting largely of sandstone, grit, and quartzite, with more or less pervading mica, as far as the journey extended in the Schurwe Bergen, also parallel to the former ranges. The maximum thickness of the successive strata is calculated by the author at 24,000 ft.; allowing for possible reduplications, the minimum is regarded as not less than 9,000 ft.—On some Bivalve Entomostraca, chiefly Cypridinidæ, of the Carboniferous formations, by Prof. T. R. Jones, F.R.S. The larger forms of bivalved Entomostraca are not rare in the Carboniferous limestone, and some occur in certain shales of the Coal-measures.

Geologists' Association, May 2.—H. Woodward, F.R.S., president, in the chair.—On the valley of the Vézère (Perigord), its limestones, caves, and pre-historic remains, by Prof. T. Rupert Jones, F.R.S., F.G.S. The river Vézère, rising in the department of Corrèze, traversing the department Dordogne, and joining the river Dordogne near Larlat, runs from the old metamorphic rocks of the central plateau of France, through carboniferous, triassic, jurassic, and cretaceous strata. The last mentioned are chiefly limestones, nearly horizontal, presenting steep and often high cliffs, either washed by the river, or bordering its broader and older valley. The softer bands of limestone have been hollowed out along the valley by frost and water, and here and there present recesses and caves. These in several instances have been artificially enlarged, and in very many cases have afforded shelter to pre-historic people, and still retain heaps of bones and hearth-stuff, with flint implements of numerous kinds, carved bones and antlers, and occasionally human bones. The most common bones and antlers are those of reindeer, which must have abounded in southern France, whether remaining all the year round or migrating from plain to mountain and back again in their season, for the cave-folk killed them of all ages in vast numbers. The cold climate necessary for the reindeer has long passed away; the musk-ox and the hairy mammoth disappeared also with the reindeer; and looking at the great changes in geographical outlines and contours that have taken place since the extinction of the European mammoth, the author thought that some eight or nine thousand years would not be too long for the bringing about of such changes. That the Old cave folk of Périgord saw the living mammoth, a lively outline sketch of its peculiar and shaggy form, on a piece of ivory, found in the Madelaine Cave, is satisfactory evidence. The special geology of the district, the characters of the several caves and their contents, and the most striking of the implements of stone and bone were described in this paper; the human remains found at Cro-Magnon, a gigantic chief and his more ordinary companions, were specially treated of; and the high probability of their belonging to the same race of men as the older Cave-folk was discussed at some length. (For details on this subject see NATURE, vol. vii. p. 305 *et seq.*)

Anthropological Institute, May 6.—Col. A. Lane Fox, V.P in the chair. A paper was read on "Eastern Coolie Labour," by Mr. W. L. Distant. The aim of the paper was to show the dissimilarity in the capacity and aptitude for certain work which exists among different peoples under the same conditions. The working of a large sugar estate by means of European capital, European appliances, and European superintendence, with the manual labour of some hundreds of Asiatics, including Klings, Chinese, Javanese, and Malays, was taken as an example. In describing the labours of these peoples, the differences were examined in their capacity for work in general, their aptitudes and dislikes for certain work, and also in their methods of working, viz. by task or otherwise, taken in conjunction with their social condition, and the terms under which they are engaged. In contact with the European the Chinaman seems to prosper; he bargains with him, whilst the Javanese sullenly works for him, and the Kling sinks to a crouching menial in his presence. The European seems affected in the same way; he can chat with the Chinese, tolerate the Javanese, but despises the Kling. Europern civilisation and prejudice are confronted with Eastern ignorance and prejudice. It is the need of money that has brought these different peoples together. English, Scotch, Portuguese, Klings, Javanese and Chinese are only attracted together in the hope of gain, and under this creed progress and civilisation generally remain in the hands of the strongest and richest party.—A paper by Mr. Howorth was read on "The westerly Drifting of Nomads from the fifth to the nineteenth century, Part x.: the Alans or Lesghs." Col. Lane Fox exhibited two beautifully chipped flint bracelets, four iron bracelets, and other articles found in a tomb in the valley leading to the tombs of the Kings of Thebes; also a large and finely worked flint knife from a tomb in the same neighbourhood. Lieut. S. C. Holland, R.N., exhibited a series of photographs of Ainos, and various articles of Aino manufacture.—The Rev. Dunbar I. Heath has been elected Treasurer in the place of the late Mr. Flower.

Zoological Society, May 6.—Prof. Newton, F.R.S., vice-president, in the chair. The secretary read a report on the additions that had been made to the Society's menagerie during the months of March and April, 1873, and called particular attention to an example of the Broad Banded Armadillo (*Xenu-*

rus unicinctus), which was new to the Society's collection; also to a pair of White-necked Cranes (*Grus vipio*) from Japan. No example of this fine species, so far as was known, had previously been brought alive to Europe.—Mr. Sclater exhibited some photographs of, and made some remarks on, a young specimen of the Liberian Hippopotamus (*Hippopotamus liberiensis*) which had recently been received alive by the Zoological Society of Ireland, but had died shortly after its arrival.—A communication was read from the Rev. O. P. Cambridge on some new species of Araneidea, chiefly from Oriental Siberia.—A communication was read from Mr. G. B. Sowerby, jun., on three species of land shells from Madagascar, which he proposed to call *Cyclostoma suffusum*, *C. vexillum*, and *C. perspectivum*, sps. nov.—A communication by Messrs. P. L. Sclater and O. Salvin contained notes on the range of certain species of American *Limiocolæ* in the southern part of the New World. Two distinct species of Stilts (*Himantopus*) were shown to occur in the Neotropical region—namely, *H. nigricollis* Viell., and *H. brasiliensis* Brehm.—Mr. A. H. Garrod read a memoir on the variations of the carotid arteries of birds, in continuation of the labours of Bauer, Meckel, and Nitzsch upon this subject. Mr. Garrod's observations were based principally upon specimens that had died in the Society's gardens.

Entomological Society, May 5.—Mr. H. T. Staunton, vice-president, in the chair.—Mr. Higgins exhibited a specimen of *Langia zeuzeroïdes* (one of the Sphingidæ), from the Himalaya, bred by Major Buckley. He also exhibited a female specimen (the first that he had ever seen) of *Goliathus albosignata*, from Limpopo.—Mr. McLachlan exhibited a coloured plate of butterflies as a sample of a work on the "Natural History of Turkestan," about to be published at the expense of the Government of that place, and founded on the entomological collections made by M. Alexis Fedtscheuko during the years 1869–71. The work is to be published in the Russian language, with Latin diagnoses of the new species.—Mr. Bates pointed out a figure in the plate of *Cocandica*, a variety of *Colias nastes*, an insect belonging to Lapland, and remarked that it was an interesting fact that many species of insects belonging to Arctic regions were also found in mountainous districts much farther south, though not in the intervening plains. He mentioned also *Colias palæno*, which was found near the snow-line, in the Alps, and in Lapland.—Mr. Müller also remarked on the close connection between the Arctic and Alpine insect faunas, referring particularly to *Parnassius apollo*, which occurred in the north of Europe, but in Switzerland was confined to the Alps and the opposite Jurassian range, carefully avoiding the intervening alluvial plains, which in the glacial period had been covered with the glaciers of the Rhone, the Reuss, the Rhine, and minor tributaries. He added that if the actual stations of the species were mapped, they would all be found to exist outside, but along the moraines left by the ancient glaciers.—Dr. Sharp communicated a paper on the Staphylinidæ of Japan," principally from the collections formed by Mr. George Lewis.—A paper was read, entitled "Notes on the Ephemeridæ," by Dr. H. A. Hagen, compiled by the Rev. A. E. Eaton.

Royal Horticultural Society, May 7.—General Meeting.—Viscount Bury, M.P., having been nominated by the Council, pending the Queen's approval, to the office of president, took the chair.—The Rev. M. J. Berkeley commented upon the show. Prof. Thiselton Dyer called attention to the first appearance at the meetings of *Odontoglossum vexillarium*, a lovely orchid, with flat rose-coloured flowers, four inches across. It had flowered for the first time in the old world on April 19.· The late Mr. Bowman discovered it in New Grenada, on the western slopes of the Andes. It was more nearly allied to *O. phalænopsis* than to the type generally prevailing in the genus.

Scientific Committee.—Dr. J. D. Hooker, C.B., F.R.S., in the chair.—The Rev. M. J. Berkeley exhibited a shoot of *Araucaria imbricata*, illustrating the injury suffered by this plant from the punctures of the young leaves by the prickly points of those on the other branches.—Dr. Masters exhibited a drawing of a flower of Mr. Ware's *Primula veris* var. *chlorantha* It consisted of a mass of small leafy scales, the innermost of which were prolonged into styles and had ovules upon the edges.—Prof Thiselton Dyer, adverting to some statements about the cultivation of fungi, stated that, according to Thore, cited by Duchartre, *Agaricus Palomet* and *Boletus edulis* are sown in the Landes by watering the soil with water in which these species had been boiled. The spores of various other species will, it is said, endure a temperature of 212° F., and those of *Peziza repanda* even, according to Schmitz, 230° F.—The Rev. M. J. Berkeley said there was no doubt that fungus spores would bear a high temperature. The development of a *Penicillium* in the interior of loaves of the *pain de munition* almost immediately after they were drawn from the oven to the temperature of which the spores must have been fully exposed, was a case in point. Specimens of *Cytinus hypocistis*, the only European species of *Rafflesiaceæ*, were shown. They had been sent from Cannes by the Hon R. Bailie Hamilton.

Institution of Civil Engineers, May 6.—Mr. T. Hawksley, president, in the chair.—The paper read was a history of the River Clyde, by Mr. James Deas, and gave an account of the various works carried out for improving it as a navigable river, and of the modes and cost of dredging and depositing followed in the deepening and widening of it. It was remarked that for no river in the kingdom had so much been done "by art and man's device" as for the Clyde above Port-Glasgow; that the river from Glasgow, for twelve miles seaward, was nearly as much an artificial navigation as the Suez Canal. One hundred years ago the river was fordable even on foot twelve miles below Glasgow. The engineering works carried out in the Clyde, combined with the mineral resources of the district, had raised Glasgow from an insignificant provincial town, with a population in 1771 of only 35,000, to be the second city in the empire, with a population (including suburbs) of 566,150, according to the census of 1871.

Royal Microscopical Society, May 7.—Dr. Millar, V.P., in the chair.—A paper by Dr. Maddox was read, "On a parasite (believed to be a species of *Tœnia*) found encysted in the neck of a sheep." The general characteristics of the cyst and the appearance of sections of it under the microscope were fully described, as were also such portions of the parasite as could be separated from the general mass, and in which the presence of immature ova was particularly noted. The circumstance of finding ova during the encysted condition of the creature was believed to be unique.—A paper was also read by Mr. W. K. Parker "On the Development of the Facial Arches of the Sturgeon," in which the formation and development of the mouth was minutely described, and the relation which it bore to that of the osseous fishes and to mammals pointed out.

PHILADELPHIA

Academy of Natural Sciences, January 14.—Dr. Ruschenberger, president, in the chair.—Prof. Cope made some observations on the structure and systematic position of the genus *Eobasileus* Cope. *Uintatherium* Leidy and *Dinoceras* Marsh were names applied to allied mammals, so that the same would probably apply to them also. Until further evidence is presented, he adheres to his original position, that these animals are true *Proboscidia*, and cannot be referred to any other order.—"On the Forms of Artificial Oxide of Zinc," by George A. Koenig, Ph.D.—"On a Boiler Incrustation from New Jersey," by George A. Koenig, Ph.D.

January 21.—Dr. Bridges in the chair.—Notice of Fossil Vertebrates from the Miocene of Virginia. Prof. Leidy directed attention to some fossils, part of a small collection recently received. They were found imbedded in blue clay containing an abundance of fossil diatomes, among which Coscinodiscus is especially conspicuous. The fossil vertebrate remains consist mainly of vertebræ and teeth of cetaceans, vertebræ of bony fishes, teeth of sharks, and spines of rays. Among them also there is a portion of a humerus of a bird, and several worn teeth of a peccary. Besides these there are specimens which may be regarded as characteristic of the following undescribed species: *Protocamelus virginiensis*, *Tautoga* (*Protautoga*) *conidens*, *Acipenser ornatus*.—Mr. Thomas Meehan offered to the Academy some facts in regard to the fertilisation of flowers which confirmed the popular view that pollen of one variety had an immediate influence on the structure of the fruit of another variety, as well as on the progeny; and also furnished some entirely new facts in regard to the ability of a seed germ to receive impregnation from two distinct sources. Mr. Arnold of Paris, Canada, determined to observe the effect of cross fertilisation on Indian corn. He procured a very peculiar variety of which Mr. Meehan exhibited an ear, not known in the vicinity—a brown variety, with a circular dent at the apex—and raised one plant from it. The first set of flowers were permitted to be fertilised by their own pollen in order to test whether there was any reversionary tendency in the plant, or the pollen of any other variety in the vicinity. The ear now produced was the result

—every grain being like its parent. The corn plant produces two ears on each stalk. As soon as the "silk"—the pistils of this second ear—appeared, the pollen—in a "tassel"—of the common yellow flint corn was procured, set in a bottle of water tied near the developing ear, the plant's own tassel having been cut away sometime previous. After a short time this set of male flowers was removed, and a panicle of male flowers from a white variety was introduced to the same bottle in order to afford it the opportunity of operating on the same female flowers. The result was the ear now presented. The base of *each grain* was of the yellow flint corn, but the *upper half* of the white variety. The result was he thought no escape from the conclusion, not only that there was an immediate influence on the seed and the whole fruit structure by the application of strange pollen; but the still more important fact, hardly before more than suspected, that one ovule could receive and be affected by the pollen of two distinct parents, and this too after some time had elapsed between the first and second impregnation.

February 4.—Mr. Vaux, vice-president, in the chair.—The following papers were presented for publication:—"On the Lingual Dentition of certain Terrestrial Pulmonata from the United States, with remarks on their systematic value," by Thos. Bland and Wm. G. Binney; "Catalogue of the recent species of the Class Brachiopoda," by W. H. Dall, U.S.C.S.; "Descriptions of Mexican Ichneumonidæ," by E. T. Cresson. "Notices of Remains of Fishes in the Bridger Tertiary Formation of Wyoming." Prof. Leidy remarked that among the multitude of fossils which had been collected from the tertiary clays and sandstones of the Bridger Group of Wyoming, there were comparatively few pertaining to fishes. Nevertheless the remains of these are not unfrequent, but they are not so complete as one might have expected from the nature of the beds containing them. They usually occur as isolated bones, scales, and teeth, and mostly indicate fishes related with our living Gars (*Lepidosteus*) and Mud Fish (*Amia*). Many of the fragments appear to indicate the following extinct species previously undescribed:—*Lepidosteus atrox; L. simplex; L. notabilis; Amia* (*Protamia*) *uintaensis; A.* (*Protamia*) *media A.* (*Protamia*) *gracilis*); *Hypamia elegans; Pimelodus antiquus; Phareodus acutus.*

Paris

Academy of Sciences, May 5.—M. de Quatrefages, president, in the chair.—The deaths of Baron Liebig, foreign associate of the Academy, and of M. Hausteen, correspondent, were announced.—The following papers were read:—On the heat produced by the reactions between water and ammonia, calcic, baric, and strontic, oxides, by M. Berthelot. The author had estimated the heat produced by the solution of dry NH_3 in water, and also on the dilution of the former solution with more water; he has found that as regards the latter case the heat is in inverse ratio to the water already combined with the ammonia. The determinations of the heat in the case of calcic, baric, and strontic oxides, was made by dissolving them in HCL, and from the result obtained the heat for their combination with water was calculated.—On the separation of potash and soda in vegetables, 5th memoir, by M Eug. Peligot. The author finds that in those cases where plants growing near the sea contain sodium salts, this fact is to be attributed to their absorption of them, through their leaves, from the spray in the air, and not from the soil.—A report on M. Bertin's memoir on the resistance opposed to rolling by the keel of a vessel, by MM. Paris, Jurien de la Gravière, and Dupuy de Lôme.—On the conditions of the integrability of simultaneous equations, &c., by M. Collet.—On the use of the meat of tuberculous animals for food; can this meat cause the development of pulmonary phthisis? by M. G. Colin. The author, from the results of thirty experiments where as many animals were fed on every kind of tuberculous flesh, answers the question in the negative. Where other experimenters have obtained opposite results, he believes that they have either experimented on animals already diseased, or have allowed portions of the tuberculous matter to find admission to the lungs of the animals in the air they breathed.—On the action of ozone on absolute alcohol: on the combination of hydrogen and cyanogen under the influence of the silent electric discharge, by M. A. Boillot.—A new observation of comet II., 1867, by M. Stephan.—On the effects produced by electricity on mercury immersed in different solutions, by M. Th. du Moncel.—On the purification of hydrochloric acid by M. Engel.—On the estimation of sugar by Barreswil's method by M. E. Feltz.—Experiments on the respiration of fish, by M. Quinquand.—Contribution to the history of microzymes and Bacteria: physiological transformation of Bacteria into microzymes and of mycrozymes into Bacteria in the digestive tube of the same animal, by MM. Béchamp and Estor.—On the remains of *Elephas priscus* found in the quaternary formation of the environs of Paris, by M. J. Reboux.

DIARY

THURSDAY, May 15.

Royal Society, at 8.30.—On the Periodicity of Rainfall in Connection with the Sun-spot Periodicity: C. Meldrum.—On the Heating of a Disc by rapid Rotation in Vacuo: B. Stewart and P. G. Tait.—On Jeypoorite: Major Ross.—Determination of the number of Electrostatic Units in the Electromagnetic Unit made in the Physical Laboratory of Glasgow University: D. McKichan.

Society of Antiquaries, at 8.30.—Remarks on some Pictures by Quintin Matsys and Holbein, in the Collection of the Earl of Radnor, at Longford Castle, lately exhibited at the Royal Academy: J. G. Nichols.

Chemical Society, at 8.—On Isomerism: Dr. H. E. Armstrong.

Numismatic Society, at 7.

Royal Institution, at 3.—Light: Prof. Tyndall.

FRIDAY, May 16.

Royal Institution, at 9.—Limits of Certainty in Taste: Sidney Colvin.

Horticultural Society, at 3.—Lecture.

SATURDAY, May 17.

Royal Institution, at 3.—Ozone: Prof. Odling.

MONDAY, May 19.

London Institution, at 4.—Elementary Botany: Prof. Bentley.

Asiatic Society, at 3.—Anniversary.

Victoria Institute, at 8.—Anniversary.

Society of Arts, at 8.—Cantor Lectures. On Wines; their Production, Treatment, and Use: J. L. W. Thudichum, M.D.

TUESDAY, May 20.

Royal Institution, at 3.—Early Roman History and Architecture.

Institution of Civil Engineers, at 8.

Statistical Society, at 7.45.

Anthropological Institute, at 8.—On the Egyptian Colony and Language in the Caucasus: Hyde Clarke.

Zoological Society, at 8.30.—On African Buffaloes: Sir Victor Brooke, Bart.—Remarks on varieties of the Carp: Lord Arthur Russell.—On *Lepilemur cheirgaleus*, and on the Zoological rank of the *Lemuroidea*: St. George Mivart.

WEDNESDAY, May 21.

Meteorological Society, at 7.—Discussion on Proceedings of Meteorological Conference at Leipzig.—On Land and Sea Breezes: J. K. Laughton.—Notes on a a Double Rainbow observed at Kirkwall: R. H Scott.—On some Results of Temperature Observations at Durham: I. J. Plummer.

Horticultural Society.—Exhibition of Ericas, Pelargoniums, &c.

Society of Arts, at 8.—Recent Processes for the Production of Gas for Illuminating Purposes: Thomas Wells

THE FUTURE OF THE ENGLISH UNIVERSITIES

AN ECHO FROM OXFORD

THE Association for the Organisation of Academical Study has inaugurated a good work, which must in the end have an important result. But in the expressions of policy as yet put out by that body we notice an omission which perhaps is intentional, but in any case a very serious, indeed a fundamental one. It is well enough to declare that the collegiate and other revenues of Oxford and Cambridge should be devoted to the encouragement of research, and to placing the highest kind of teaching in all subjects within the reach of the people of this country. It is most true that to this end prize-fellowships and non-resident sinecures must be abolished, and in their place we must have carefully-chosen professors, assistant-professors, and lecturers, teaching and carrying on original research in all departments of knowledge. With such a programme in hand the members of this association can very plausibly demand for the old Universities that they be not despoiled of their excessive wealth, but that this wealth be made operative and productive within the limits of the Universities themselves. Nevertheless there is a question which necessarily arises—whenever the future of the English Universities is mentioned—which the Association has not discussed, and which we think it ought boldly to meet, even though it should lead to a split in the ranks. That question is this—Are Oxford and Cambridge to remain as institutions exclusively for the elegant education—the "culture"—of the upper classes who may choose and can afford to allow their sons to while away certain years there? or are they to be made engines of national education where a poor man may go with as much reason as a rich one; and profitably spend his time in acquiring knowledge and training which have a real value in the world and place their possessor in the position to earn his bread and his standing among men?

It is a fact that at this moment a youth entering a college at either Oxford or Cambridge and taking his degree after four years of a very pleasant life, having spent during the process at least 800*l.* (*i.e.* 200*l.* a-year) comes away, not a whit further on in the battle of life than he was on entering. He has acquired some good habits, many very bad ones, but has received no training nor instruction which will render him useful to other men, excepting—the exception is a very significant one—as a clergyman or as a schoolmaster.

The state of things is neither more nor less than this—that a young man cannot study at the English Universities and associate with even the most steady-going of his fellow-students at a less expense than that named above; and that the University cannot, at any rate does not, teach him anything in a practical or professional way. It is useless for Cambridge and Oxford to open their classes to non-collegiate students, as long as those classes are not something more systematised and practically-pointed than they can be, when exclusively designed as parts of a so-called elegant or "liberal" education. Men who are intending to work hard in life cannot afford to pass through such a course after leaving school; and hence our University students are, with a few exceptions, drawn from the richer classes; hence, too, the amount of luxury and rarity of earnest study amongst them, which re-acts on many of their teachers. The present position of the Universities with regard to education for the business of life is merely that of a preparatory school. The same limitations of subjects—the same books are in force here, with some small additions for the few "honour men," as in our public schools, such as Eton, Harrow, and Rugby. The B.A. degree—the ordinary examinations for which any average boy on leaving school at sixteen or eighteen years of age could easily pass—absorbs nearly all the activity; is, in fact, almost the highest effort of each University. Almost all the teaching, certainly all the college work, is directed and governed by the requirements of this preparatory course which prepares for nothing. Whilst the intellectual standard thus held up is childish enough, it is necessarily accompanied by a system of tutorial superintendence and direction as wearisome as it is injurious.

In fact, the best effort in Oxford and Cambridge—the most striking movement in recent times—as compared with the dead calm of some fifty years since, has been rather a retrogression than an advance; we are less of Universities now than then, and have become more like—and are daily becoming more like—the great public schools, such as Eton and Harrow. The greater part of all the college-teaching staff is employed in doing the very same work as that done in the schools, which ought never to be required at a University at all. As the arrangements and innovations of the various college-bodies are watched, it becomes obvious that the schoolmaster is abroad in a very ambitious spirit with the avowed object of making the University a great Seventh Form, similar in discipline and character of instruction to his own pedagogic institution.

This state of things is defended by a large number of persons—among them members of the Association—with two words chiefly in their mouths—"culture" and "technical." It is maintained that "technical education" (an expression which is used for the purpose of suggesting the less intellectual side of what it is better to term "professional education") is not the function of the Universities, that it cannot be conveniently undertaken in them, that it is better carried out in the great cities such as London, Manchester, Edinburgh, whilst the Universities in their academic seclusion can administer that smattering of omniscience, dilettantism, and good manners which it is so important for persons of a certain income to possess. To obtain this a youth must be prepared to sacrifice time and money; and in offering this the University is, according to the opinion of many resident fellows, doing its work in the world. The selfishness of this view of University functions is patent enough. Clearly it is an easier matter to undertake this ornamental work, and to leave to others the business of life. It appears to be overlooked by its advocates that the Universities thus may, or rather have, lost all influence, all share in the life of the country. In

renouncing technical or professional education, the University renounces all those who must have such education at the age when she might receive them. Those who really value, as we do above most things, breadth of intellectual interests—who have intense repugnance to narrow "specialism"—cannot, upon due consideration, defend the separation of "ornamental" and "technical" education, as likely to conduce to increase of culture among our fellow-countrymen. It is by undertaking most fully the charge of the higher education—of those for whom without distinction such education is necessary—that the Universities can really do most for the cause of culture. When Oxford and Cambridge succeed in getting hold of all such students then only can thoroughly satisfactory results be expected by those who are anxious for the progress of the higher education. What we desire more earnestly is, that Oxford and Cambridge may be the means of giving breadth of view and interest to as large a number of young Englishmen as possible, for it is this that we understand by "culture:" not the mere ease of manner due to luxury and the select association of leisured men. Oxford and Cambridge can spread true culture, and can have pretensions to such an office only when acting up to their trust and fully providing for the very best and fullest professional study in all departments. There are some to whom it appears important that the Association should plainly declare itself on this matter, before proceeding to the question of the foundation of institutions for scientific and literary research within the University. If on the one hand the Association were to declare for the exclusion of professional study, and at the same time to advocate the foundation of increased means and material of research within the University, we should feel at once that the policy of the Association would not be accepted by all. There is a great deal of human nature in the men who occupy distinguished positions in our Universities, and in the select atmosphere of non-professional students and cultured ecclesiastics there is an inevitable languor and repose of the mind which are infectious. The most vigorous body becomes limp before the sirocco, and in this atmosphere of luxurious culture it may be doubted whether even Faraday could have carried out his investigations: probably only by investing himself in a kind of mental diver's costume. On the other hand, the presence of an active body of those who for want of a better word we may call professional students—of men who, having neither time nor money for self-indulgence, determinedly work round their professor—the presence of a whole lot of such professors each so surrounded, and the association thus established between the Universities and the progress of the body of the country in the arts and sciences, would bring about a gigantic change. Professors so surrounded might with advantage be largely increased; the purely ornamental students would be by no means dislodged—they would remain in numbers then as now—but beneficially influenced by the example of the career-seeking and professional student. These in their turn would be benefited by a duly proportioned infusion of those students seeking exclusively "culture"—the amateurs and patrons of serious pursuits.

It is, then, only on the basis of professional training in the widest sense of the term, that we should care to see a reorganisation of Oxford and Cambridge. Let the colleges be taxed, say, to the extent of fifty per cent. of their revenue in order to support the professoriate and the appliances which each faculty may deem adequate, not only for direct "student teaching," but for progressive research. Then we may hope to see our Universities elevated from the condition of mere finishing schools for young gentlemen. If such a plan cannot be carried out, it would seem useless to simply create sinecures within the old places, larger and probably less productive than those which at present exist. Sharp and painful though the measure might be—we should in that case have to yield to the removal of means which have so long lain idle. The colleges would be relieved of their excessive income to support more practical institutions elsewhere, and Oxford and Cambridge would collapse into the condition of mere theological seminaries. When the Association meets on Saturday next, it would be well that this point should be raised, lest by the silence of the leaders of the movement, any one should be lukewarm in its support.

FRICK'S PHYSIKALISCHE TECHNIK

Oder Anleitung zur Anstellung von physikalischen Versuchen und zur Herstellung von physikalischen Apparaten mit möglichst einfachen Mitteln. Von Dr. J. Frick. (Braunschweig, 1872)

THIS most useful book has now reached the fourth edition, and has swelled to 700 pages, illustrated by 986 wood engravings. To some British physicists and teachers the work has already proved itself serviceable, but there are doubtless many to whom it is at present unknown who would find much valuable information therein.

Dr. Frick's work is not in any sense a manual of experimental physics; it is rather an elaborate treatise upon physical apparatus and the methods of physical research. Its object, we learn from the preface, is to give an introduction to the methods of conducting physical inquiry, to enumerate the precautions which it is necessary to adopt in order to ensure success, and to give ample directions with reference to the construction of apparatus and its management. This field is, comparatively speaking, untrodden before, and we have no hesitation in saying how thoroughly successful Dr. Frick's attempt to guide us over it has proved. We shall briefly indicate the contents of the book, and then point out the few matters in which we think the execution of the task has fallen short of what might have been fairly expected.

The first part contains a sketch of the arrangements necessary for the physical laboratory, and a detailed account of the methods of manipulating glass, metals, and other materials which are required for the apparatus described in the second part. This portion of the book is very interesting and useful. We find here numerous hints on turning, glass-blowing, and similar processes with which it is well for the physicist to be acquainted. In the second part we have in Chap. I. a description of the apparatus necessary for the study of the equilibrium of forces applied to solids, liquids, and gases; Chap. II. describes the apparatus used for experiments on motion

Chap. III. is on acoustics ; Chap. IV. on light ; Chap. V. on magnetism ; Chap. VI. on electricity ; Chap. VII. on heat. It may be remarked that the figures are drawn to scale, and further illustrations of the details are added whenever necessary.

As a fair specimen of the illustrations and descriptions we may refer to Article 121, wherein is described Müller's apparatus for studying experimentally the free falling of a body. This beautiful contrivance is for the purpose of causing a point vibrating horizontally to trace a curve upon a board descending vertically. From the form of the curve the law of falling bodies is deduced. In Chap. IV. we meet with many interesting contrivances : for example, Fig. 433 represents an arrangement for showing the principle of the rainbow experimentally by the aid of spheres of glass. This chapter is concluded by a practical lesson in photography. Many of the figures in Chap. VI. will be found to represent electric instruments which are manifestly great improvements on forms in ordinary use. As an example we refer to the Rheostat, Fig. 775.

Considering the book has already reached such portly dimensions we can hardly complain of omissions. We are, however, of opinion that the space at the disposal of the author might have been more judiciously employed if some of the apparatus which he has described were omitted and some instruments which he has passed over were inserted instead. To illustrate this remark we may refer to the chapters on mechanics. We there find a number of ingenious contrivances generally pretty well known, but we also meet with toys like those described in articles 66 and 67 which could, we think, have been very well dispensed with. On the other hand we seek in vain in the same chapter for a full account of Willis's system of mechanical apparatus. To say that this ingenious system would, with trifling additions, enable all the mechanical experiments described by Dr. Frick to be performed is to give a very inadequate idea of its resources. In the hands of a competent experimenter Willis's apparatus will be found to provide in a substantial form the principal parts necessary for nearly every conceivable experiment in mechanical philosophy. The framework of this apparatus is so useful in almost any physical research that we cannot conceive how it could have been omitted from "Physikalische Technik," had the author of that work been acquainted with the writings of Prof. Willis. We think also that some of the host of merely qualitative experiments described for the purpose of illustrating centrifugal tendency (Article 124) might very well be omitted. On the other hand, we miss Smeaton's machine, which, admitting as it does of exact quantitative results being determined. is perhaps, next to Atwood's machine, the most useful instrument we have for illustrating the truths of dynamics.

We are tempted to think that Dr. Frick is not adequately acquainted with English scientific literature. This opinion receives some confirmation when, on turning over 238 closely-printed pages which describe electrical apparatus, we fail to see Sir William Thomson's beautiful instruments described ; nor on turning to the Index do we even find the name of that philosopher mentioned.

Although we decidedly think this book might have been better, yet we decidedly think that it is very good, and we cordially recommend it to the notice of physicists and lecturers, who will certainly find it useful.

OUR BOOK SHELF

Electricity. By R. M. Ferguson, Ph.D., F.R.S.E. (W. and R. Chambers.)

We regret that the Elementary Treatise on Electricity has not been revised by its author since its first appearance. For example, useful as is the chapter on the absolute measurement of an electric current, its usefulness to students would be increased by a fuller and more detailed explanation. At the foot of p. 159 it is stated that "the heating effect (of the current) depends on the strength of the current and the resistance." It should be the *square* of the strength of the current into the resistance, as is correctly stated in a preceding paragraph. On p. 153 there is a mistake in the calculation of the quantity of water decomposed by a current ; 60 c.c. $\times$ tan. $51\frac{1}{3} = 75$ c.c., and not 80 c.c., as is stated, and afterwards assumed. A description of the sine-galvanometer ought hardly to have been omitted, and a fuller explanation, together with an engraving of Thomson's reflecting galvanometer, ought surely to be given. There is also but a meagre account of the induction coil, and the function of the condenser is not explained : the term *rheotom* instead of contact-breaker, looks pedantic, and may puzzle some readers. But the most faulty part of the book in our estimation is the singularly obscure and misleading manner in which the terms Electric Quantity and Tension are defined on p. 64. Tension is spoken of as synonymous with electric depth, or as the French say, electric thickness ; whereas the tension, pressure, or power of discharge possessed by any electrified point, varies as the *square* of the electric depth at that point.

The first part of this text-book relates to magnetism and more evident care has been bestowed on this portion. The charts of isogonic and isoclinic lines are most useful, and so also are the chronological appendices, in which a brief scientific history of each subject is given. But why could not the dip and declination be given for a later year than 1865? It is said on page 16 that two magnetic needles are absolutely necessary to show "the power of the earth in determining the position of the needle," and that "if it were possible to hang a needle in the air so as to leave it perfectly free to take any position, it would show us fully the directive action of the earth." Is it not possible to buoy a magnetic needle in water, or sink it in mercury, so that the action of gravity may be neutralised, and the directive influence of the earth wholly come into play? Moreover, many dipping needles are made with a swivel pivot, by means of which the declination and dip are roughly shown at the same time. Two other blunders we notice in the part on magnetism. On page 4, speaking of a "small magnetic bar or needle," Dr. Ferguson says that "if both poles of the needle are attracted indifferently by any end of it [a bit of iron], it is not magnetic." This is as slipshod in its science as it is in its English, for it is precisely the test of a magnetic body that it does attract either end of the needle ; magnetic should of course read magnetised, and so again a few lines lower down. The other blunder is on page 14, where it is said that "cobalt is attracted by the magnet at the highest temperatures." It is well known, and can easily be shown as a class experiment, that cobalt loses its magnetic character at a white heat. But in spite of these errors, Dr. Ferguson's "Electricity" is a book that has been of much use to both teachers and students of science. Its obvious merits lead us to hope that a revised edition may find it free from the defects to which we have drawn attention.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Forbes and Tyndall

At p. 387 of the recently published "Life and Letters" of the late Principal Forbes, the following passage occurs:—

"I believe that the effect of the struggle—though unsuccessful in its immediate object—will be to render Tyndall and Huxley and their friends more cautious in their further proceedings. For instance, Tyndall's book, again withdrawn from Murray's 'immediate' list, will probably be infinitely more carefully worded relative to Rendu than he at first intended."

This passage has been selected, among others, by Principal Shairp, the editor of this portion of the "Life," from a letter addressed to A. Wills, Esq., under date of November 14, 1859: the "struggle" to which it refers arose out of an attempt on the part of some influential friends of Principal Forbes, who were at that time members of the Council of the Royal Society, to obtain the Copley medal for him; and it took place at the Council meetings which were held on October 27 and November 3, 1859.

I was not a member of the Council at this time, and therefore, I could take no direct part in the "struggle" in question. But, for some years before 1859, glaciers had interested me very much; I had done my best to inform myself in the history of glacier research; I had followed with close attention the controversy which had been carried on between Prof. Tyndall and his friends, on the one hand, and Principal Forbes and his supporters on the other; and, finally, I had arrived at a very clear conviction that the claims made for Principal Forbes's work, could not be justified.

Under these circumstances I thought it would be a most unfortunate occurrence if the Council of the Royal Society, containing as it did, not a single person who had made the glacier question his especial study, should practically intervene in the controversy then raging, and throw its weight upon the side of one of the combatants, without due consideration of what was to be said on the other side.

A friend of mine, who was a member of the Council, shared these views; and, in order to enable him to enforce them, I undertook to furnish him with a statement which he could lay before the Council when the award of the Copley medal came up for discussion.

It is not necessary to state what took place at the meetings of the Council—suffice it to say that the Copley medal was not awarded to Principal Forbes.

So far, therefore, as my statement may have contributed to this result, my efforts were completely successful. Principal Forbes's very influential champions in the Council were left, as I am informed, in a hopeless minority; and instead of tending to make me more cautious in my "future proceedings," what occurred on this occasion should have emboldened me.

The notion expressed by Principal Forbes that I and Prof. Tyndall's other friends were in any way discouraged by the results of our battle, is therefore strangely erroneous; however, I do not know that the error would have been worth correction, if Prof. Tyndall had not been referred to as one of those who took part in the fray. But, in justice to Prof. Tyndall, I am bound to say that he knew nothing about the battle until after it was over. My ally in the Council and I, agreed, for reasons which will be obvious to any honourable man, that Prof. Tyndall, though an intimate friend of ours (and largely because he was so), ought not to have any knowledge of the action we took; and, in a note dated November 4, 1859, I find myself suggesting to my friend in the Council, that Tyndall ought to be kept in his then ignorance "until his book is out." I have every reason to believe that this suggestion was carried into effect; at any rate, Prof. Tyndall did not see the draft of my statement till a year ago when (on May 13, 1872) I sent it to him accompanied by some other documents and the following note:—

"Routing among my papers yesterday I came upon the inclosed cinders of an old fire, which I always told you you should see some day. They will be better in your keeping than mine."

I am informed that there was not even an attempt to controvert the leading points of my statement on the part of the advocates of Principal Forbes's claims; and therefore the assertion that Prof. Tyndall was led to word "infinitely more carefully" what he had already written about Rendu, by anything which occurred in the Council, is simply preposterous.

In making these remarks I have no intention of throwing the slightest blame upon the late Principal Forbes; who surely had a perfect right to express to an intimate friend whatever impression was left upon his mind, by such reports as reached him of the occurrences to which he refers. But I confess I find it difficult to discover any excuse for the biographer, who deliberately picks the expressions I have quoted out of a private letter, and gives them to the public, without taking the trouble to learn whether they are, or are not, in accordance with easily ascertainable facts.

T. H. Huxley

May 17

Forbes and Agassiz

In the review of Dr. Tyndall's book on the "Forms of Water" which appeared in Nature, vol. vii. p. 400, the following words occur:—"But surely it was not unnecessary to rake up again the Forbes-Rendu controversy, nor to renew the claims of Agassiz and Guyot." Mr. Alexander Agassiz takes exception to this (see Nature, vol. viii. p. 24) and makes the following assertions:—That when a guest of Agassiz on the glacier of the Aar in 1841, Forbes returned the hospitality of Agassiz "by appropriating what he could" from the work of the latter, and "misrepresenting the nature of his intercourse with Agassiz." This refers to a matter of facts and may be proved or disproved by the facts. It refers to an attack made upon Forbes in 1842, which was immediately answered by him in a manner that left no room for further discussion. I must necessarily be brief in stating the facts. They may be found fully detailed in the *Edin. New Phil. Journal*, 1843, or in the "Life and Letters of James David Forbes, 1873" They are as follows:—In 1841 Forbes enjoyed the pleasure of a visit to Agassiz on the Unteraar Glacier. On the first day of their sojourn (August 9), their only companion was Mr. Heath, of Cambridge. They were afterwards joined by friends of Agassiz. On this first day Forbes pointed out to Agassiz the veined structure of the ice. Agassiz had spent five summers studying the glaciers (see Mr. Alexander Agassiz' letter in Nature), but he replied "that it must be a superficial phenomenon, that he had on a previous occasion noticed such markings, and that they were caused by the sand of the moraines causing channels of water to run." Forbes showed him that the structure was general, even in the body of the glacier. Agassiz expressed a doubt "whether the structure had not been superinduced since the previous year." Forbes afterwards showed him that in a crevasse three or four years old the markings extended across the crevasse and were visible in continuation from one side to the other. Further, Forbes insisted upon its intimate connection with the theory of glaciers. When in the ensuing winter M. Desor wrote to Prof. Forbes denying his claims to the discovery, the latter sent him a statement of the above facts, begging that M. Agassiz should state whether they were correct or not. M. Agassiz wrote an answer to this letter. He does not deny a single one of the facts supplied by Forbes in connection with the observations of August 9. This letter was printed and circulated by M. Agassiz. Furthermore, when these facts were published by Forbes, even then M. Agassiz did not deny any of them. Moreover, Mr. Heath, the only other witness, gives his evidence in support of the accuracy of the above facts (see "Life of Forbes," Appendix B, Extract I.). Other friends of Agassiz, who joined them afterwards, wrote to Forbes stating their belief that to him alone belonged the discovery. After leaving the Aar glacier Forbes extended his observations. He showed (1), that the structure was common to most, if not all, glaciers (see "Forbes' Life," p. 550, note); (2), that this was the cause of the sand lying in lines ("Life," p. 548); (3), that this was also the cause of the supposed horizontal stratification of the terminal face of some glaciers (Royal Soc. Edin., 1841, Dec. 6); (4), he showed that these blue markings were the outcroppings of blue ice that formed lamellar surfaces in the interior of the glacier; (5), he actually determined the shape of these surfaces in the case of the Rhone glacier (R. S. E., 1841, Dec. 6); (6), he remarked that "the whole phenomenon has a good deal the air of being a structure induced perpendicular to the lines of greatest pressure," though he did not assert the statement to be general. This was in 1841. In later years he extended these observations. I have said enough to prove (1), that although Agassiz carried with him "a geologist, a microscopic observer, a secretary, a draughtsman, and many workmen," and though he had spent five summers studying the glaciers, he did not see these markings (or at any rate recognise them as a structure of the ice) until Forbes showed them to him; and (2), that Forbes recognised this structure as an important "indication of

an unknown cause" ("Occasional Papers," p. 4), and worked out the subject thoroughly.

In the *Comptes Rendus* for Oct. 18, 1841, a portion of a letter from Agassiz to Humboldt was published. Here he lays claim to the discovery without mentioning the name of Forbes. He speaks of it as "le fait le plus nouveau que *j'ai* remarqué." Forbes felt deeply annoyed at this conduct of his friend, but contented himself with publishing his own discovery. A rupture between the two friends now commenced. About this time M. Guyot recollected that he had described this appearance in 1838 to the Geological Society of France, at Porrentruy ("Agassiz Etudes," p. 207). Several people had seen the same thing previously. Among others, Sir David Brewster writes as follows:—"The Mer de Glace is like the waves of the sea, as if they had been fixed by sudden congelation; when the ice is most perfect, which is on the sides of the deep crevices, the colour is a fine blue. There is an appearance of a vertical stratification in the icy masses stretching in the direction of the valley in which the glacier lies. . . . The surface of the glacier exhibits also the appearance of veins exactly like blocks [?] of stone" (*Journal*, 1814). In 1820, M. Zummstein saw it ("Bibliothèque Universelle," 1843). Col. Sabine and M. Elie de Beaumont had also seen it ("Travels in the Alps," p. 29). But though seen it had not been studied, nor did any printed description of it exist. M. Guyot did not even print an abstract of his communication. It remained an isolated, unprinted, forgotten fact until Forbes appeared upon the scene. Professor Tyndall has most justly said that neither Forbes nor Agassiz knew of it in 1841 ("Forms of Water," p. 187). Yet though, as has just been proved, Forbes pointed it out to Agassiz in 1841, the latter tried to show that he had known of Guyot's observation (letter from Agassiz to Forbes, "Life of Forbes," Appendix B), and endeavoured to give the credit to Guyot rather than to Forbes (his own claims having been now disproved). If it be true that he knew what Guyot had done, then (1) why did he not mention it to Forbes and Heath, both of whom affirm (in contradiction to the statements of Agassiz) that Guyot's name was not mentioned? (2) Why did he not perceive the importance of the structure? (3) Why did he say that it was superficial? (4) Lastly, how could he reconcile it with his conscience to describe it to Humboldt as "le fait *le plus nouveau* que *j'ai* remarqué?"

The facts show (1) that Forbes was seriously wronged by the conduct of Agassiz; (2), that he discovered independently the veined structure; (3) that he was the first to study the subject and give it its true place in reference to glacier theories. I have limited myself to the accusation contained in the letter of Mr. Alex. Agassiz. Whether he is correct in his appreciation of the estimate put upon Forbes' labours, in Dr. Tyndall's last popular work, I need not at present discuss. I know so well to what conclusion a comparison of that book with the writings of Forbes and other workers on glacier theories would lead, that I leave it confidently to the judgment of those "fair-minded investigators" of whom Mr. Alex. Agassiz speaks.

GEORGE FORBES

P.S.—Mr. Heath's testimony, to which I have referred, is given in the following extract from a letter dated Trinity College, Cambridge, Feb. 25, 1842:—"I will witness—1st, that he (Agassiz) knew nothing about it; 2nd, when he did see it he said it was superficial *sand*; 3rd, that he was the last to believe that it went to any depth. I think your account very true, and not claiming one jot more than fully belongs to you."

Cambridge, May 20 G. F.

Perception and Instinct in the Lower Animals

THE suggestion made by me in your issue of February 20, that animals which had been deprived of the use of their eyes during a journey might retrace their way by means of smell, had the effect of letting loose a flood of illustration, fact, and argument bearing more or less directly on the question; and as the stream now seems to have run nearly dry, I ask permission briefly to review the evidence adduced, so far as it affects the particular issue I brought forward. Several of the writers argue as if I had maintained that in all cases dogs, &c., find their way, wholly or mainly, by smell; whereas I strictly limited it to the case in which their other senses could not be used. The cases of this kind adduced by your correspondents are but few. The first, and perhaps the most curious, is that of Mr. Darwin's horse; but, unfortunately, the whole of the facts are not known, As Mr. Darwin himself pointed out, the horse may have lived in the Isle of Wight, and been accustomed to go home along that very road. I would suggest also that the country might resemble some tract in the neighbourhood of his own home; or that the horse, having been brought from home by a route and to a distance of which it had no means of judging, thought its master was riding home on the occasion in question, and therefore objected to turning back. Anyhow, the case is too imperfect to be of much value as evidence in so difficult a matter. "J. T." (March 26) quotes the case of the hound sent "from Newbridge, county Dublin, to Moynalty, county Meath," thence long afterwards to Dublin, where it broke loose, and the same morning made its way back to its old kennel at Newbridge. I can find no "Newbridge, county Dublin," although there is a Newbridge, county Kildare, which is 26 miles from Dublin, on a pretty direct high road. That the dog never attempted to return during its "long stay" at Moynalty seems to show that some special facilities existed for the return from Newbridge. What they may have been we cannot guess at in the total absence of information as to the antecedents of the dog, the route by which he returned, and the manner in which he conducted himself on first escaping in Dublin.

The next case, of the two dogs returning from Liverpool to near Derby, is vague, and also without necessary details. It happened 50 years ago, and the only evidence offered as to the mode of the dogs' return is that "*it is said* they were seen swimming the Mersey." "N. Y.'s" case (April 24) of the dog who "did not make haste back," and therefore could not have returned by smell, is also most inconclusive. The distance was only 20 miles, and we know nothing of the route the dog followed, or the time it took. How do we know the dog did not wait the three weeks till it saw someone it knew living at or near its former house, and followed that person? This appears to me to be an exceedingly probable way of accounting for many of these returns where the distance is not very great. This brings me to the case of Mr. Geo. R. Jebb, who seems to have gone to the trouble of making an experiment which, with a little more trouble, might have been very complete and satisfactory. The dog was taken by rail very circuitously from Chester to a place 10 miles from Chester. It "hung about the station for about an hour and a half," and in three hours more arrived at its home. But we are still left totally in the dark, both as to the route it took or the process by which it decided on that route. What is required in such experiments is, that a person not known to the dog should be ready to watch and follow it (on horseback), noting carefully on the spot its every action. We should then perhaps know why it "hung about the station" an hour and a half before commencing its journey home, and afterwards, whether it showed any hesitation as to its route, and whether it followed the road or went straight across country. A few experiments carefully made in this way, at distances varying from 10 to 30 miles, and with a thorough knowledge in each case of the animal's antecedents, would, I venture to say, throw more light on this interesting question than all the facts that have been yet recorded. The only experiment of this kind I have met with is in the work of Houzeau ("Etudes sur les Facultés Mentales des Animaux"), and it is so curious that I give the passage literally. He says (vol. i. p. 156): "I have succeeded in making young dogs of five or six months lose themselves on first going out with me. They would begin by seeking for my trace by smell; but not succeeding in this, they would decide to return home. If there was a path, they followed the route by which they had come. If it was an untrodden virgin country, they shortened the circuits they had made in coming, but did not altogether depart from them. One would say that memory furnished a certain number of points which divided the route, and they went towards these by memory of directions. Thus inscribing chords to the curve by which they had come, they returned to the house." M. Houzeau's general conclusion from a considerable body of observations made with this point in view is, that animals find their way by exactly the same means as man does under similar circumstances, that is, by the use of all their faculties in observation of locality, but especially by a memory of directions and by a ready recognition of places once visited, which serve as guide-posts when they are again met with. This seems to me a very sound theory, and quite in accordance with all that is known of the manner in which savages find their way.

The more general objections to my little theory which are made in your leading article appear to depend on the denial, to such animals as dogs and horses, of that amount of common

sense and reasoning power which I believe them to possess, and also to the assumption that in the case supposed they would recollect merely the odours, not the objects the presence of which these odours had indicated. I imagine that animals know, just as well as we do, that some sights, sounds, and smells are caused by permanent, others by evanescent or changeable causes. The smell or sound of a flock of sheep would indicate to a dog the presence of an actual flock of sheep, just as surely as the sight of them would do, and he would no more lose his way because those sheep were not in the same place the next day or the next week, than he would had he travelled the road on foot with his eyes open. The smell of a wood, of a farmyard, of a ditch, a village, or a blacksmith's shop, with the more or less characteristic sounds accompanying these, would tell the dog that corresponding objects were there just as surely as the sight of them would do. On his return he would recognise the objects, not the smells and sounds only, and he would be no more puzzled by the absence of certain moveable objects he had recognised by smell than he would be had he seen them. I quite believe that mistakes would often be made owing to the discontinuousness of sufficiently characteristic odours; but the process of "trial and error," suggested by F.R.S., would be constantly used, and this is in accordance with the length of time usually taken in these journeys, often very much longer than would be required for a return by the shortest route and at moderate speed.

A friend has communicated to me a most remarkable fact, of a different character from any which have been referred to during the course of this discussion; and as I have it at first hand and took the exact particulars down as narrated to me, I think it will be of value. Many years ago, my friend lost a favourite little dog. He was then living in Long Acre. Three months after, he removed to a house in another street about half a mile off, a place he had not contemplated going to or even seen before the loss of the dog. Two months after this (five months after the dog was lost) a scratching was one day heard at the door, and on opening it the lost dog rushed in, having found out its master in the new house. My friend was so astonished that he went next day to Long Acre to an acquaintance who lived nearly opposite the old house (then empty) and told him his little dog had come back. "Oh," said this person, "I saw the dog myself yesterday. He scratched at your door, barked a good deal, then went to the middle of the street, turned round several times, and started off towards where you now live." My friend cannot tell, unfortunately, what time elapsed between the dog's leaving the old and arriving at the new house. If every movement of this dog could have been watched from one door to the other, much might have been learnt. Could it have obtained information from other dogs (and that dogs can communicate information is well shown by Mr. A. P. Smith's anecdote in your issue of three weeks back)? Could the odour of persons and furniture linger two months in the streets? These are almost the only conceivable sources of information, for the most thorough-going advocates for a "sense of direction" will hardly maintain that it could enable a dog to go straight to its master, wherever he might happen to be.

Not to trespass further on your space, I would venture to hope that some persons, having means and leisure, would experiment on this subject in the same careful and thorough way that Mr. Spalding experimented on his fowls. The animals' previous history must be known and recorded; a sufficient number of experiments, at various distances and under different conditions, must be made, and a person of intelligence and activity must keep the animal in sight, and note down its every action till it arrives home. If this is done I feel sure that a satisfactory theory will soon be arrived at, and much, if not all the mystery that now attaches to this class of facts be removed.

ALFRED R. WALLACE

The Origin of Volcanic Products

I HAVE not yet had the advantage of seeing Mr. Mallet's translation of Palmieri's late work on Vesuvius, but have read with interest Mr. Forbes's review thereof and Mr. Mallet's reply in NATURE of Feb. 6 and March 20. I have no desire to enter into a controversy, but as I have for the past fifteen years taught and defended a theory of the origin of volcanic products identical with that now maintained by Mr. Mallet, I may be permitted to say a few words. That the source of all such matters was to be found not in the earth's nucleus but in sedimentary strata, was taught by Keferstein in his *Naturgeschichte des Erdkörpers*, in 1834; and again, doubtless independently, by Sir J. F. W. Herschel in 1837; while, for my own part, I was led to the same conclusion before I became aware of the views of either of my predecessors, solely from a consideration of the varying composition of plutonic rocks and of the stony and vaporous products of volcanic action. To the views of Herschel I first called attention in the *Canadian Journal* for March 1858, and again in the *Quar. Geol. Journ.* for November 1859, pp. 488–496, § vii.).

In the first of these I have said: "If we admit that all igneous rocks, ancient plutonic masses, as well as modern lavas, have their origin in the liquefaction of sedimentary strata, we can at once explain the diversities in their composition. We can also understand why the products of volcanoes in different regions are so unlike, and why the lavas of the same volcano vary at different periods. We find an explanation of the water and carbonic acid, which are such constant accompaniments of volcanic action, as well as the hydrochloric acid, sulphuretted hydrogen, &c." The nature of the reactions between siliceous, calcareous, and aluminous strata, holding carbonaceous matter, gypsum, sea-salt, &c., was then discussed, and the products of their transformations under the influence of water at an elevated temperature considered. In both of these papers referred to, the inadequacy of the views of Phillips, Durocher, and Bunsen, to explain the origin of these various products, was maintained.

In the *Geological Magazine* for June 1869, I returned to this subject in a paper on "The Probable Seat of Volcanic Action," where, after repeating and enforcing the above views, I said: "Two things become apparent from a study of the chemical nature of rocks; first, that their composition presents such variations as are irreconcileable with the simple origin generally assigned to them; and second, that it is similar to that of the sedimentary rocks whose history and origin it is, in most cases, not difficult to trace." In what follows I endeavour to show in the latter the source of such "eruptive rocks as peridolite, phonolite, leucitophyre, and similar rocks, which are so many exceptions in the basic group of Bunsen."

Mr. Mallet has, however, made a very important advance in this theory of volcanic action by pointing out a source of heat independent of the cooling nucleus. Keferstein had supposed heat to be generated by chemical action in the sediments, and his view has lately been brought forward, in a modified form, by Leconte; but this I have always rejected as untenable. The chemical actions supposed to be involved in the processes would consume rather than generate heat. I have hitherto followed Herschel and Babbage in regarding the heat as directly derived by conduction from an incandescent nucleus, but Mr. Mallet has now shown that the work expended in the crushing of the strata which takes place in certain regions of the globe where the contraction which attends the slow refrigeration of the globe is displayed in corrugations of the crust, is more than adequate to explain volcanic heat. To this it must be added that, inasmuch as the crushing process takes place in strata which, from their depth, are already at an elevated temperature, the heat developed by the mechanical process comes in to supplement that derived by conduction from the igneous centre. Vose had already, in a general manner, pointed out the same thing, suggesting in terms which are, it is true, wanting in scientific precision, the notion that the mechanical force at work in the crushing of the strata was the source of heat. This, however, in no way detracts from the great merit of Mr. Mallet, who may rightly claim "to have been the first to apply weight, measure, and number to volcanic theory," and we await with great interest the publication of his quantitative results. Apart from his thermo-dynamic theory, however, his views of volcanic action are apparently identical with those of Keferstein and Herschel, to which I have for many years been endeavouring to give form and consistency. I may here call attention to a paper, "On some Points of Dynamical Geology," published in the *American Journal of Science* for this month (April 1873), in which I have already alluded to the foregoing questions, and to the endeavours which I have for fifteen years been making "to reconstruct the theory of the earth on the basis of a solid nucleus." I have there rehearsed the views which I have all this time maintained as to the causes which determine the process of corrugation of the earth's crust, the accumulation of sediments, and the development of volcanic activity in certain regions of the earth; thus giving a theory of the geological and geographical distribution of past and present volcanoes.

Kinetic Theory of Gases

On page 300 of the second edition of Maxwell's excellent little text-book on the "Theory of Heat," it is stated, as a result of the kinetic theory of gases therein set forth, that "gravity produces no effect in making the bottom of the column" (of gas) "hotter or colder than the top."

I cannot see how this result follows from the kinetic theory of gases. On the contrary, it seems obvious that thermal equilibrium can only subsist according to the kinetic theory, where the molecules encounter each other with equal average amounts of *work* or *vis viva*, and in order that this may be the case, the velocity of the molecules (and consequent temperature) of any upper layer must be less than that of the molecules in the layer next below; since, in order to encounter each other, the former must descend, and acquire velocity, while the latter must ascend and lose it. This would establish a diminution of temperature from the bottom to the top of a column of air at the rate (in the absence of any counteracting cause) of 1° F. for 113 ft. of height, as can easily be verified from the fact that on account of the specific heat of air 1 lb. requires 183 foot-pounds to raise its temperature 1° F. Radiation may diminish this and tend to produce equilibrium, but nevertheless it seems obvious from these two opposing tendencies a residual inequality of thermal condition would result, and that the top of a column would be cooler than the bottom. That this would be the case if the air were in general motion in the form of upward and downward currents, will not, I presume, be disputed; and surely molecular is on the same footing. If the particles of air are moving in every direction with great absolute velocity, in what respect does this differ from air currents? In fact, all the particles which at any epoch of time are moving in any given direction constitute an air-current in that direction, mingled, it is true, with currents in other directions, but moving with accelerated velocity if descending, and with retarded velocity if ascending, and thus always tending to produce a diminution of temperature with height as a condition of gaseous thermal equilibrium. J. Guthrie

Graaf Reinet, Cape Colony, April 2

Kerguelen Cabbage

I would like to know, through your paper, whether the naturalists of the *Challenger* have orders to attempt to collect the seeds of the Kerguelen Land cabbage (*Pringlea antiscorbutica*). It has often occurred to me that the attempt ought to be made to introduce this plant on the seashores of Northern Europe and America. John R. Jones

Milwaukee, Wisconsin, U.S. April 14

Yorkshire Terrier Story

The anecdote of the instinct of dogs given in the number of Nature, May 1, p. 6, is identical with one to be found in Bewick's "History of Quadrupeds," p. 367, 1800, which he calls the well-known story of the "Dog at St. Alban's."

The same story precisely, with some dramatic embellishments and names, occurs in "Bingley's Animal Biography," vol. 1, p. 223. A.

Dorking

BICHROMATE PHOTOGRAPHS

A singular discovery has recently been made touching the action of light upon substances rendered sensitive by the bichromates of potash and ammonia, which threatens to revolutionise photographic printing altogether, at any rate so far as the production of permanent prints is concerned. The printing by means of silver salts in the ordinary way, which is still in vogue with nearly all portrait photographers, will always find application, by reason of the simplicity of the manipulations and the delicate and pleasing nature of the results, albeit all silver photographs enjoy the unenviable notoriety of being perishable. First of all, they lose their pristine brilliancy and freshness, then a sickly yellowness gives place to the glossy whites of the picture, and finally the deep bronze shadows become of a flat brownish tint, which grows weaker and weaker as time goes on. To secure permanent photographs, which shall possess all the beauty and detail exhibited by silver prints, has been for many years the aim of photographic experimenters, and it was not until Swan and Johnson had contributed their well-known improvements that the production of a delicate photograph in permanent pigments became at all possible. Mechanical photographic processes, where the pictures are printed off in a press, are still beset with many difficulties of a practical nature, the most perfect of them—Woodburytype—requiring further elaboration before perfect prints of large dimensions can be secured.

Pigment photographs, or carbon prints, as they are generally termed, require three elements for their production—a pigment (such as Indian-ink, lamp-black, or some such substance), gelatine, and bichromate of potash, or ammonia. A compound of these three substances is spread upon paper, and termed pigment or carbon tissue. This tissue is printed under a transparent negative in the sun, the light acting more or less energetically upon the sensitive pigment, and rendering it insoluble in parts, so that when it is immersed subsequently in warm water certain portions refuse to wash away, and these form the image; during the exposure of the tissue to light, these parts have in fact become fixed by its action. This, as we all know, is what takes place in the formation of a carbon print.

It has been found that the action of light upon a bichromate film is very different in its nature to the result produced by the sun upon iodide of silver. A film of pure iodide of silver, as Dr. Reissig and Mr. Carey Lea have abundantly shown, may be impressed with an image which will fade out altogether if the film is afterwards preserved for a sufficient time screened from light. Indeed it is possible to impress iodide of silver with an image, allow the same to fade away in darkness, and then impress the film with a second and different picture. The photographic image, therefore, on iodide of silver is of an evanescent nature, becoming weaker and weaker, and, if preserved for any time, ultimately fading away altogether. Now, with a photograph upon a bichromate film, the reverse is the case. If an impression of the slightest kind is produced upon a film of gelatine sensitised with bichromate, and put away in the dark, the action of the light still goes on, and progresses until the image has become a perfect and vigorous one. This continuation of the solar action has been turned to good account by carbon printers, who in winter time and busy moments have printed their photographs in darkness instead of light; that is to say, in lieu of exposing their sensitive tissue in the sun under a negative for hours and hours, they merely do so for a few minutes, the slight image thus impressed being allowed to gain in vigour subsequently by preservation for some time—half-a-day or so—in darkness, before development in warm water. In the ordinary way only half-a-dozen copies can be obtained from one negative during the day, if all of them are fully printed in the sun, whilst if only incipient prints are produced, a score of impressions may easily be secured.

Within the last few days we have progressed a step further in carbon printing. M. Marion of Paris has discovered that if you take a bichromate image printed in the sun, and put it into contact with another bichromate surface, you produce upon the latter a similar impression. You can in fact take a carbon picture fresh from the frame and employ it as a printing block, from which any number of impressions are procurable. It is a most singular fact that a solarised surface should be capable of setting up an action upon another sensitive surface placed in contact with it. But so it is. The impression made by light upon a bichromate film is capable of transmission to another surface of like nature merely pressed against it. We have, as it were, stored up in the original print a quantity of sunlight which has been

absorbed and may afterwards be communicated to other surfaces.

The importance of this discovery can scarcely be overrated, and there is no doubt but that it will work an era in the matter of carbon printing. We need secure but one single photograph printed in the sun in order to obtain a large number of copies, all of which shall be as delicate and vigorous as if they had been printed by sunlight. A sheet of gelatine sensitised with bichromate of potash is put under a negative and printed; it is withdrawn from the printing frame and immersed in a weak solution of bichromate of potash which swells up those portions of the surface that have not been attacked by light, and thus produces a picture in relief. The sheet of gelatine is then put into a press and impressions from it taken on sensitive carbon tissue, the block being moistened from time to time with bichromate solution. The copies thus produced upon the tissue are not fully printed and cannot be developed at once; they are simply incipient, or nascent, pictures, it must be mentioned, and they require preservation in the dark for some hours to allow the action of the light to continue, exactly in the same way as if the carbon tissue had been exposed to sun-light for a few minutes. When the prints have been kept sufficiently they are developed in warm water, and fine vigorous copies are the result. Naturally enough if the tissue is kept too long after, the mordant action of the light continues rendering the film insoluble, and then the development of the image in warm water obviously becomes impossible.

Another application of the same principle has been made by M. Marion, in which carbon printing is assimilated to silver printing, to such a degree, that those accustomed to the ordinary method of printing photographs on albumenised paper, would find no difficulty in adopting it. H. BADEN PRITCHARD

ON THE METHOD OF COLLECTING AND PRESERVING ENTOMOSTRACA AND OTHER MICROZOA

CONSIDERING the varied interest which attaches to the Entomostraca, it has long seemed to me that they attract a remarkably small share of attention from microscopists. In the case of so widely distributed and numerous a group, this cannot arise from any real difficulty in procuring materials for study; but I believe it does arise in great measure from a want of information as to the best means of capturing and preserving specimens. I propose, therefore, briefly to point out some of the methods which in my own hands have best answered these ends.

Classification.—The Entomostraca constitute, as all microscopists know, a division of the class Crustacea, and for the purposes of the present paper we may with sufficient approach to accuracy consider them as forming four groups—*Cladocera*, of which the common *Daphnia*, or water-flea, is the type; *Ostracoda*, typified by the little hard-shelled, bivalve, mollusc-like *Cypris*; *Copepoda*, represented by the well-known *Cyclops*; and the parasitic species, *Pœcilopoda*, commonly known under the name "fish-lice."

Respecting the last-named group, I shall have nothing to say here; the mere knowledge of their mode of life indicates the method of capture.

Habitat.—All collections of still-water, large and small, from the mere road-side pool to the mountain lake and the ocean, support, with scarcely an exception, their quota of entomostracan inhabitants; nor is purity an essential condition of their existence, for sometimes they are found in great numbers when one would think the foulness of the medium too much for animal existence of so high a grade. Doubtless, however, a moderate purity of water is necessary to the presence of any great variety of species; a luxuriant aquatic vegetation is also very favourable to the growth of most Entomostraca, affording them probably not only food, but shelter. For this reason the weedy margins of lakes are as a rule much more prolific than the clear central portions, where, indeed, but little microscopic life usually exists. Rapidly flowing water is of course unfavourable to the existence of these organisms, but the sea, both between tide marks and in the open, abounds with them. Ostracoda, except the fresh-water Cyprides, live for the most part on the bottom, and are therefore to be obtained chiefly by dredging. The brackish water of salt-marshes and estuaries supports its own peculiar species, some of which often occur in prodigious numbers; and even the highly saline waters of brine springs and salt lakes have been found to contain Entomostraca.

Methods of Collecting

1. *Freshwater.*—An ordinary "ring-net," made of "hard muslin," or "crinoline," from six to twelve inches in diameter, and fitted to the end of a walking-stick, will be found the most convenient apparatus for the capture of such swimming species as haunt the weedy margins of ponds and lakes. For such shallows as are matted with a growth of *Littorella, Lobelia*, or other dwarf ground-plants a "horse-shoe" net, with a frame made after the fashion of a Dutch hoe, is very serviceable; while in working from a boat in the centre of a lake the ordinary ring-net on a stick will be quite sufficient. In this way the net will, after working for a few minutes, usually be partially filled with fragments of weed and other *débris*, amongst which there will also be found a fair sample of the Microzoa inhabiting the locality. The coarsest fragments, such as stems of rushes and portions of water weeds, may conveniently be picked out with the fingers, and thrown away, while the rest of the contents of the net must be transferred to a bottle of clear water, an eight-ounce being a convenient size for the purpose. The Microzoa may then be readily separated by filtering into another bottle through a net of sufficiently wide mesh to allow of their passage through it: "mosquito-netting" I have found to answer well for this purpose. Having thus obtained our Entomostraca in a condition tolerably free from admixture with extraneous matter, they may easily be collected in a patch on the centre of a piece of fine muslin by passing the whole through a piece of that material, arranged over a funnel. They should then be transferred at once (if it be not wished to keep them alive) to a small phial of some preservative fluid. This may be effected easily by a penknife, but a very convenient instrument for the purpose is an ordinary quill toothpick. This process, which appears somewhat cumbrous in writing, is in reality very easily performed, but it may be still further simplified, according to the fancy of the collector, by fitting an outside funnel with a muslin net, and having a small inner one of perforated zinc, so as to do all the filtering at one operation. The collecting net may also be protected from the entrance of very coarse rubbish by a light, moveable wire grating. The species obained by these means will often include numerous representatives of all three orders, Cladocera, Ostracoda, and Copepoda. For the capture of such Ostracoda as haunt the bottom in parts too deep to be reached by a walking-stick, a small hand-dredge is required: this will be more particularly noticed in the marine section.

2. *The Sea.*—The free-swimming species, the great majority of which belong to the order Copepoda, may be most conveniently captured by the walking-stick net held over the side of a row-boat in gentle motion. Care should be taken that the lower end of the net is as wide or wider than its mouth, and that the material, while close enough to retain the Entomostraca, is yet open enough to allow a free current of water through it: if those points be not attended to the result will be a back-wash, carrying back out of the net much which should have been retained.

A towing-net dragged by means of a line from the side or stern of the boat may be used, but is not so much under control, and seldom produces so much spoil : such a net, however, attached in a tide-way during the night to some stationary object, and made with the precautions mentioned above, will often do good work, especially if its specific gravity be adjusted so as to sink very slightly below the surface. As a rule, indeed, the hours from dusk to midnight seem to be the best for capturing pelagic species near the surface. In tidal pools on the shore the same appliances are required as for fresh-water ponds.

Ostracoda and other deep-dwelling species require, of course, the use of the dredge ; and where Microzoa only are the objects sought, the dredge may conveniently be made of a size much smaller than those in ordinary use. The mouth need not be more than 6 in. in its largest diameter, the bag being made of coarse canvas or "cheese cloth," and from 18 in. to 2 ft. long. The material so dredged up, after having been passed through suitable sieves, so as to separate the coarser portions, should be washed in a muslin bag for the purpose of removing all the impalpable mud, which often constitutes a very considerable proportion of the bulk : this operation may most easily be performed over the side of the boat in the sea, or in some large vessel of sea-water. The washed material is then to be put up in canvas bags, duly labelled, and hung up in a warm position to dry ; the more rapidly this part of the process is conducted the better chance will there be of preserving the internal parts, as well as the valves of the Ostracoda, in good condition. But should it be wished to secure the animals actually alive, the best plan will be, after washing the mud as above explained, to immerse a quantity of it in a basin of sea water, allowing it to stand for an hour or more, when many of its inhabitants will have made their way to the surface of the water. They will, indeed, continue to come to the surface for many hours, but the later ones will probably be sickly or dead.

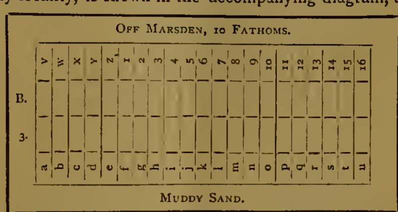
But besides Ostracoda, there are often great numbers of Copepoda in or on the ooze and sand of the sea-bed. These require for their separation a different method of procedure ; the following, so far as I know, being the most convenient. After the process of sieving described in the preceding paragraph, all the minute swimming animals will be found in the water in which that operation has been conducted ; all that is necessary, therefore, is to pour the water off through a muslin net in which the Microzoa will be retained—in a dirty state, however, which will render careful washing desirable, or still better, the transference of the whole to a bottle of clean sea water for an hour or two ; in this way the little creatures will clear themselves of adherent dirt better than we can do by any amount of washing.

A very rich field for the collecting of Copepoda is found in the groves of Fuci and Laminariæ so common on rocky shores at and beyond low-water mark. The fronds of these weeds having been dragged up in any convenient way, are to be washed, a handful or two at a time, by brisk agitation in a tub of sea water, after which the water is to be filtered as directed above. It is best not to macerate weeds in the water for any great length of time, because much mucus exudes from the Laminariæ, enveloping the Entomostraca, and rendering it an extremely difficult and tedious matter to examine the gathering properly. It should be mentioned that, although all weeds harbour numbers of Entomostraca, *Laminaria saccharina* is, as a rule, by far the most productive, apparently on account of the rugosities of the frond affording more efficient shelter to their minute inhabitants : sheltered pieces of coast and land-locked bays are much the most productive hunting grounds.

Treatment of Dredged Material.—The separation of Ostracoda, Foraminifera, and other Microzoa from dredged sand or mud, is best accomplished by the process of "floating." For this purpose the material should be thoroughly well dried and sifted, so as to insure the fine division of the whole mass, then placed in a vessel of water and thoroughly stirred. By this means all the lighter organised particles—chiefly Ostracoda, Foraminifera, minute Mollusca, fragments of Polyzoa, &c.—will, owing to their contained air, be brought to the surface, and may be removed in any convenient way, but best, perhaps, by pouring off the supernatant water through a very fine gauze sieve. Some of the larger and heavier species will, however, sometimes remain at the bottom, and must be picked out with the help of a hand lens.

Fossiliferous Clays and Shales.—These, after repeated maceration in water, should be passed, time after time, through fine sieves, so as to wash out the impalpable suspended mud ; at last drying the residuum and floating out the organic particles, as previously directed. When much fossilised, however, the Microzoa will not float. In this case they must be picked out one by one from the residuum left after the repeated washings.

Preservation of Specimens.—Soft-bodied species, *e.g.*, Copepoda, Cladocera, &c., are best preserved in methylated spirit, either of full strength or diluted with an equal quantity of water, the latter, in my opinion, being preferable, as it does not so readily evaporate entirely if left unattended to in small bottles for a length of time. The great disadvantage of alcohol is that it coagulates the albuminous tissues, rendering the animals almost opaque, at the same time destroying the natural colour ; but most other preservative solutions possess these properties to a greater or less extent, and have likewise other drawbacks, such, for instance, as becoming cloudy, permitting the growth of fungi, &c. When, however, it is especially wished to preserve the colours, a mixture of equal parts of glycerine and distilled water answers admirably. Indeed, the only hindrances to its general use as a preservative for Microzoa are its strongly solvent action on calcareous tissues and its inconvenient stickiness. For microscopic mountings (of non-calcareous objects) some kind of "glycerine jelly" answers admirably ; especially that described by Dr. Carpenter in his book on the microscope, which preparation is, however, improved by saturating with arsenious acid the water used in its manufacture. Ostracoda and other dry specimens require, of course, no preparation beyond mounting on slides of wood or cardboard. An excellent plan of mounting, so as to show at one view all the Ostracoda or Foraminifera obtained in any locality, is shown in the accompanying diagram, the



slides being made of the ordinary size, of stout cardboard or millboard. The central part of the slide is cut out, and the marginal portion mounted on another slide having a dull black ground. The slide is ruled transversely, so as to divide it into any convenient number of spaces, and if needful, ruled also with one line lengthwise down the middle. Each space is marked with a figure or letter of the alphabet referring to the species mounted within it, and an index to the whole kept in a book of reference. The diagram is a facsimile of a mounting so prepared in my collection.

George S. Brady

ON THE ORIGIN AND METAMORPHOSES OF INSECTS *

IV.

On the Nature of Metamorphoses

IN the preceding articles we have considered the life history of insects after they have quitted the egg. It is obvious, however, that to treat the subject in a satisfactory manner we must take the development as a whole, from the commencement of the changes in the egg, up to the maturity of the animal, and not suffer ourselves to be confused by the fact that all insects do not leave the egg in the same stage of embryonal development. For although all young insects when they quit the egg are termed "larvæ," whatever their form may be (the case of the so-called Pupipara not constituting a true exception), still it must be remembered that some of these larvæ are much more advanced than others. It is evident that the larva of a fly, as regards its stage of development, corresponds in reality neither with that of a moth nor with that of a grasshopper. In fact, insects quit the egg in very different stages. The maggots of flies, in which the appendages of the head are rudimentary, belong to a lower grade than the grubs of bees, &c., which have antennæ, mandibles, maxilla, labrum, labium, and, in fact, all the mouth parts of a perfect insect. The caterpillars of Lepidoptera are generally classed with the vermiform larvæ of Diptera and Hymenoptera, and placed in opposition to those of Orthoptera, Hemiptera, &c. But, in truth, the possession of thoracic legs places them, as well as the similar larvæ of the Tenthredinidæ, on a decidedly higher level, while in the development of the cephalic appendages there is, as already mentioned, a marked difference between the maggots of flies and the grubs of bees. Thus, then, the period of growth (that in which the animal eats and increases in size) occupies sometimes one stage in the development, sometimes another; sometimes, as for instance in the case of *Chloëon*, it continues through more than one, or, in other words, growth is accompanied by development. But, in fact, the question is even more complicated than this. It is not only that the larvæ of insects at their birth offer the most various grades of development, from the grub of a fly to the young of a grasshopper or a cricket; if we were to classify larvæ according to their development, we should have to deal not with a simple case of gradations only, but with a series of gradations, which would be different according to the organ which we took as our test.

35

Fig. 35.—Portion of Colony of Bougainvillea fruticosa, more magnified.

Apart, however, from the adaptive changes to which special reference was made in a previous article, the differences are those of gradation, not of direction. The development of a grasshopper does not pursue a different course from that of a bee or wasp, but the embryo attains a higher state before quitting the egg in the former than in the latter; while in most Hymenoptera the body-walls and internal organs are formed before the thoracic appendages; in the Orthoptera, on the contrary, the legs

* Continued from p. 31.

make their appearance before the body-walls have completely closed round the yolk.

Prof. Owen,* indeed, goes so far as to say that the Orthoptera and other Homomorphous insects are, "at one stage of their development, apodal and acephalous larvæ, like the maggot of the fly; but, instead of quitting the egg in this stage, they are quickly transformed into another, in which the head and rudimental thoracic feet are developed to the degree which characterises the hexapod larvæ of the *Carabi* and *Petalocera*."

I quite believe that this was originally true of such larvæ, but from the tendency which large and important organs have, to appear at an early stage of embryonal development, the fact now appears to be, so far at least as can be judged from the observations yet recorded, that the legs of those larvæ which commence life with these appendages, generally make their appearance before the body-walls have closed, or the internal organs have approached to completion. Indeed when the legs first appear they are merely short projections, which it is not always easy to distinguish from the segments themselves. It must, however, be admitted, that the observations are neither so numerous, nor in most cases so full, as could be wished.

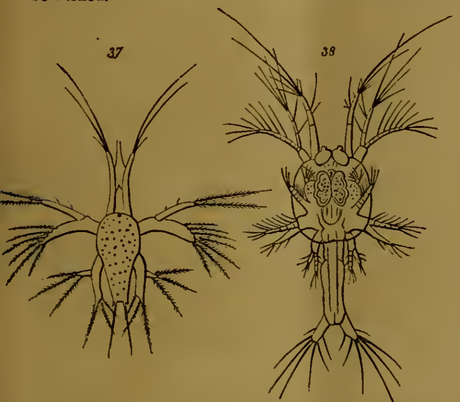

FIG. 37.—Larva of Prawn, Nauplius stage (after F. Muller). 38, Larva of Prawn, more advanced, Zoea stage.

Fig. 30, for instance, represents an egg of Phryganea, as represented by Zaddach in his excellent memoir,† just before the appearance of the appendages. It will be seen that a great part of the yolk is still undifferentiated, that the side walls are incomplete, the back quite open, and the segments only indicated by undulations. This stage is rapidly passed through, and Zaddach only once met with an egg in this condition; in every other specimen which had indications of segments, the rudiments of the legs had also made their appearance, as in Fig. 31, which, however, as will be seen, does not in other respects show much advance on Fig. 30.

Again in Aphis, the embryology of which has been so well worked out by Huxley,‡ the case is very similar, although the legs are somewhat later in making their appearance. "In embryos," he says, "$\frac{1}{140}$th of an inch in length (Pl. xxxvii. Fig. 6), I have found the cephalic portion of the blastoderm beginning to extend upwards again over the anterior face of the germ, so as to constitute its anterior and a small part of its superior wall. This portion is divided by a median fissure into two lobes, which play an important part in the development of the head, and will be termed the "procephalic lobes." I have already made use of this term for the corresponding parts in the embryos of *Crustacea*. The rudimentary thorax presents traces of a division into three segments; and the dorso-lateral margins of the cephalic blastoderm,

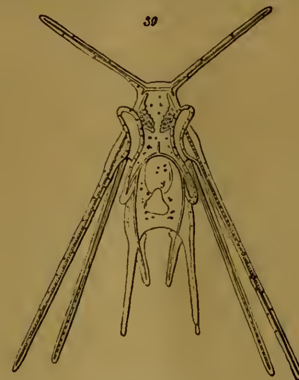

FIG. 39.—Larva of Echinocidaris, seen from above $\times \frac{6}{10}$ (after J. Muller).

behind the procephalic lobes, have a sinuous margin. It is in embryos between this and $\frac{1}{100}$th of an inch in length, that the rudiments of the appendages make their appearance, and by the growth of the cephalic, thoracic, and abdominal blastoderm, curious changes are effected in the relative position of those regions."

In *Chrysopa oculata*, one of the Hemerobiidæ, Packard has described* and figured a stage in which the body segments have made their appearance, but in which "there are no indications of limbs. The primitive band," he says, "is fully formed, the protozorites being distinctly marked, the transverse impressed lines indicating the primitive segments being distinct, and the median furrow easily discerned." Here also, again, the dorsal walls are incomplete, and the internal organs as yet unformed.

FIG. 40.—Larva of Echinus, × 100. *A*, anus; *F*, mouth process; *B*, posterior side arm; F_1, accessory arm of the mouth process; *a*, mouth; a^1, œsophagus; *b*, stomach; b^1, intestine; *o*, posterior orifice; *d*, ciliated bands; *f*, ciliated epaulets; *c*, disc of future Echinus (after J. Muller).

† "Untersuchungen uber die Entwickelung und den Bau der Gliederthiere," 1854.
‡ "Linnean Transactions," v. xxii 1858.

* "Embryological Studies on Hexapodous Insects." Peabody Academy Science. Third memoir.

In certain Dragonflies (Calypteryx), and Hemiptera (Hydrometra), the legs, according to Brandt,* appear at a still earlier stage.

According to the observations of Kolliker† it would appear that in Donacia the segments and appendages appear simultaneously. Kolliker himself, however, admits that "meæ de hoc insecto observationes satis sunt manca," and it is possible that he may never have met with an embryo in the state immediately preceding the appearance of the legs.

On the whole, as far as we can judge from the observations as yet recorded, it seems that in Homomorphous insects the ventral wall is developed and divided into segments before the appearance of the legs, but that the latter are formed simultaneously, or almost simultaneously, with the cephalic appendages, and before either the dorsal walls or the internal organs.

As it may be interesting from this point of view to compare the development of other Articulata with that of insects, I give a figure (Fig. 32) representing one of the early stages in the development of a spider (Pholcus) after Claparede,‡ who says, "C'est à ce moment qu' a lieu la formation des *protozorites* ou segments primordiaux du corps de l'embryon. Le rudiment ventral s'épaissit suivant six zônes disposées transversalement entre le capuchon anal et le capuchon céphalique. L'œuf considéré par sa face ventrale offre alors un contour à peu près circulaire et on peut le croire sphérique. Les zônes se montrent alors comme six circles d'un blanc plus éclatant, tracés sur la sphère."

Among Centipedes the development of Julus has been described by Newport.§ The first period, from the deposition of the egg to the gradual bursting of the shell, and exposure of the embryo within it, which, however, remains for some time longer in connection with the shell by a distinct funis, lasts for twenty-five days. The segments of the body, originally six in number, make their appearance on the twentieth day after the deposition of the egg, at which time there were no traces of legs. The larva when it leaves the egg is a soft, white, legless grub (Fig 33), consisting of a head and seven segments, the head being somewhat firmer in texture than the rest of the body. It exhibits rudimentary antennæ, but the legs are still only represented by very slight papilliform processes on the undersides of the segments to which they belong.

As already mentioned, I believe that at one time the vermiform state of the Homomorphous insects, which, as we have seen, is now so short, and passed through at so early a stage of development, was more important, more prolonged, and accompanied by a more complete condition of the internal organs. The compression, and even disappearance, of embryonal stages which are no longer adapted to the mode of life, which do not benefit the animal, is a phenomenon not without a parallel in other parts of the animal and even of the vegetable kingdom. Just as in language long compound words have a tendency to concision, and single letters sometimes linger on, indicating the history of a word, like the "l" in "alms," or the "b" in "debt," long after they have ceased to influence the sound; so in embryology useless stages, interesting as illustrations of past history, but without direct advantage under present conditions, are rapidly passed through, and even, as it would appear, in some cases altogether omitted.

For instance, among the Hydroida, in the great majority of cases, the egg produces a body more or less resembling the common Hydra of our ponds, and known technically as the "trophosome," which develops into the well-known Medusæ or jelly-fishes. The group, however, for which Prof. Allman has proposed the term Monopsea,* and of which the genus Ægina may be taken as the type, is, as he says, "distinguished by the absence of a hydriform trophosome, the ovum becoming developed through direct metamorphosis into a medusiform body, just as in the other orders it is developed into a hydriform body." Figure 34 represents, after Allman, a colony of *Bougainvillea fruticosa* of the natural size. It is a British species, which is found growing on buoys, floating timber, &c., and, says Allman,† when in health and vigour, "offers a spectacle unsurpassed in interest by any other species—every branchlet crowned by its graceful hydranth, and budding with Medusæ in all stages of development (Fig. 35), some still in the condition of minute buds, in which no trace of the definite Medusa-form can yet be detected; others, in which the outlines of the Medusa can be distinctly traced within the transparent ectotheque; others, again, just casting off this thin outer pellicle, and others completely freed from it, struggling with convulsive efforts to break loose from the colony, and finally launched forth in the full enjoyment of their freedom into the surrounding water. I know of no form in which so many of the characteristic features of a typical hydroid are more finely expressed than in this beautiful species."

Figure 36 represents the Medusa form of this species, and the development thus described may be regarded as typical of the Hydroida; yet, as already mentioned, the Æginidæ do not present us with any stage corresponding to the fixed condition of Bougainvillea, but on the contrary are developed direct from the egg.

But on the other hand there are groups in which the Medusiform stage becomes less and less important.

Among the higher Crustacea again the great majority go through well-marked metamorphoses. Figs. 37 and 38 represent two stages in the development of the prawn. In the first (Fig. 37), representing the young animal as it quits the egg, the body is more or less oval and unsegmented, there is a median frontal eye, and three pairs of natatory feet, the first pair simple, the two posterior biramose. Very similar larvæ occur in various other groups of Crustacea.

They were at first regarded as mature forms, and O. F. Müller gave them the name of Nauplius. So, also, the second or Zoea form (Fig. 38) was at first regarded as a mature animal, until its true nature was discovered by Vaughan Thompson.

The Zoea form of larva differs from the perfect prawn or crab in the absence of the middle portion of the body and its appendages. The mandibles have no palpi, the maxillipeds or foot-jaws are used as feet, whereas in the mature form they serve as jaws. Branchiæ are either wanting or rudimentary, respiration being principally effected through the walls of the carapace. The abdomen and tail are destitute of appendages. The development of Zoea into the perfect animal has been well described by Mr. Spence Bate‡ in the case of the common crab (*Carcinus mœnas*).

All crabs, so far as we know, with the exception of a species of land crab (*Gegarcinus*), described by Westwood, pass through a stage more or less resembling that shown in Fig. 38. On the other hand the great group of Edriopthalma, comprising Amphipoda (shorehoppers, &c.) and Isopoda (woodlice, &c.), pass through no such metamorphoses; the development is direct, as in the Orthoptera. It is true that one species, *Tanais Dulongii*, though a typical Isopod in form and general character, is said to retain in some points, and especially in the mode of respiration, some peculiarities of the Zoea type; but this is quite an exceptional case. In Mysis, says F. Muller,§ "there is still a trace of the Nauplius-stage; being transferred back to a period when it had not to

§ "Facts for Darwin," Eng. Trans., p. 127.

provide for itself, the Nauplius has become degraded into a mere skin; in *Ligia* this larva-skin has lost the traces of limbs, and in *Philoscia* it is scarcely demonstrable."

Once more, the Echinodermata in most cases "go through a very well-marked metamorphosis, which often has more than one larval stage. The distinctive character of the metamorphosis appears to be the possession by the larvæ of at least a mouth and pharynx, which, whether absorbed or cast off, is never converted into the corresponding organs of the perfect Echinoderm developed inside of the provisional organism. The mass of more or less differentiated sarcode, of which the larva, or pseudembryo, as opposed to the Echinoderm within it, is made up, always carries upon its exterior certain bilaterally-arranged ciliated bands, by the action of which the whole organism is moved from place to place, and it may be strengthened by the superaddition to it of a framework for calcareous rods."*

Thus Fig. 39 represents a larva of *Echino-cidaris*, after Muller; † The body is transparent, $\frac{6}{10}$ in length, shaped somewhat like a double easel, but with two long horns in front, which, as well as the posterior processes, are supported by calcareous rods. These larvæ swim by means of minute vibratile hairs, or ciliæ. They have a mouth, stomach, and in fact, a well-defined alimentary canal, but no nerves or other organs have yet been discovered in them. After swimming about in this condition for awhile, they begin to show signs of change. An involution of the integument takes place on one side of the back, so as to form a pit or tube, which continues to deepen till it reaches a mass or store of what is called blastema, or, as we may say, the raw material of the animal body. This blastema then begins to grow, and gradually assumes the form of the perfect Echinoderm. In doing so it surrounds and adopts the stomach of the larva, but forms for itself a new mouth or gullet, throwing off the old mouth, together with the intestine, the calcareous rods, and in fact all the rest of the body of the larva.

Fig. 40 represents a larva probably of *Echinus lividus*, from the Mediterranean, and shows the commencement of the sea egg within the body of the larva. The capital letters denote the different arms, *a* is the mouth, *a'* the æsophagus, *b* the stomach, *b'* the intestine, *f* the ciliated lobes or epaulets, *c* the young sea-egg.

EXTIRPATION BY COLLECTORS OF RARE PLANTS AND ANIMALS

THE Legislature, having very properly provided for the preservation of small birds, might extend its protection to other animals and to plants; for although it would be inexpedient to prevent individuals from taking rare insects and botanical specimens, it is surely expedient to deter persons or societies from offering premiums which are leading to the extirpation of such species.

Some years ago a judicious and formal protest against this culpable practice was published by many of the most eminent British botanists, and it has constantly been deplored by all true lovers of natural science. The respected president (the Rev. Dr. Mitchinson) of our East Kent Natural History Society, in his address at the last annual meeting thereof at Canterbury, made such strong observations on the subject as might raise the question whether local societies may not do as much harm by promoting the extirpation of rare plants and animals as good in other respects; and I have always been insisting, at the meetings of the same society and elsewhere, that it is our duty to cherish, and not destroy the precious plants and animals of the district. Whenever a rare plant or animal is exhibited at those meetings, we have always a wail about its having been "not long since often seen, [illegible] disappearing." A chief cause of this is the deplorable rapacity of collectors of and traffickers in specimens; since the preposterous notion prevails that botany and entomology consist in a recognition of the mere physiognomy, without the least regard to the physiology, of species, and being able to call them by their scientific names.

And so it will be while local societies continue to encourage such errors, instead of promulgating the essential principles of botanical or entomological science, and obstructing the injurious operations of mere collectors or pretenders. And this desirable end, so far as regards taxonomy, might be easily attained without the least harm to rare species. Prizes for the best display, illustrated by microscopic drawings and preparations of the generic and specific characters of sections or the whole of many natural orders would afford really good tests of the industry and attainments of the candidates. For example, why not try for this purpose the Willows, Grasses, or Sedges? Two of these orders have the further recommendation of being of great economic value. Again, as specific distinctions seem to be the ultimate aim of these societies, certain cells or tissues, such as the pollen, epidermis, hairs, and stomata, would afford good subjects for investigation in this point of view, as would also raphides and other plant-crystals, and very likely disclose valuable characters not yet recognised in the books of systematic botany.

I have been led to these remarks by the increasing frequency of the practice now deplored. As the "West Kent Natural History, Microscopical, and Photographic Society" is much and deservedly respected, and exercises justly considerable influence in its department, an extract from its last "Council's Report," p. 19, will suffice as a sample of the mischief:—"With a view to promote the study of Entomology and Botany among the members of the Society and their families, the Council, in the early part of the year, announced their intention of giving two prizes of 5*l*. 5*s*. each, one for the best Botanical collection, the other for the best collection of Lepidopterous Insects; all specimens to be gathered or taken within the West Kent district." This quotation is by no means intended for blame to any particular society, but merely as an example taken from one of the printed "Reports" that has lately reached me of what is still being sown broadcast generally throughout the country.

And here we have plainly not only a reward of money for the best collection of plants and Lepidoptera in a given district, but a temptation or inducement to unscrupulous collectors, in their anxiety to win the prize and defeat their competitors, to destroy such rare specimens as they may not take away. Such nefarious conduct is not meant to be insinuated of the West Kent Society; but my object is simply to assert that which I know has too often been the effect of such prizes, and to invoke the aid of NATURE in suppressing the evil.

GEORGE GULLIVER

A FRENCH PHYSICAL SOCIETY

THE scientific movement increases in France; it began about the end of the Empire, under the ministry of Duriiy, and has since taken greater proportions, especially after the last war. The new French Association for the Advancement of Science,* it is well known, is modelled after the British Association, the success of which has surpassed expectation.

The physicists of Paris have assembled for several years in the laboratories of the Superior Normal School, placed at their disposal by M. Berlin, the director of the scientific studies of this school. They conversed about [physics,

* See NATURE, vol. v. p. 357.

recent theories were set forth, the new or little known instruments were shown and explained. Thus Sir Wm. Thomson's electrometer, and several experiments of Prof. Tyndall called forth the curiosity and attention of the assistants. But those amicable meetings are no longer sufficient; the necessity of a more formal gathering was felt, as well as of writing and publishing Transactions, that the notes and observations might not be completely lost. The members of the Institute of the physical section encouraged the new society by their warm approval.

On the 17th of January of the present year, in the Salle Gerson, an *annexé* of the Faculté des Sciences of Paris (*Sorbonne*), a number of physicists met. They accepted provisional statutes and elected a board. The provisional statutes proposed by a committee composed of MM. d'Almeida, Alfred Cornu, Gernez, Lissajous, Mascart, expressed, in a few articles, the basis of the new association.

The purpose of the society is to promote physics; it will have two sittings a month alternately with the Chemical Society, and will publish transactions that will be sent to the members. The members are divided into resident, non-resident, and honorary members, the last chosen by election from among the most eminent men in France and abroad. In the first year six will be elected, and two only in each following year.

The society will be glad to receive such gifts as will facilitate its work, and will inscribe in its Transactions the names of the givers.

The board is thus composed:—President, M. Fizeau, Member of the Institute; Vice-President, M. Bertin, Director of the Scientific Studies to the Superior Normal School; General Secretary, M. d'Almeida, Director of the new Journal of Physics; Secretary, M. Maurat, Professor of Physics to the Lycée St. Louis, of Paris; Vice-Secretary, M. Alfred Cornu, Professor of Physics to the Polytechnic School; Treasurer-Archivist, M. Philippon, Secretary of the Faculté des Sciences of Paris.

The venerable M. Becquerel, who, notwithstanding his 89 years, assisted at the meeting, in order to give by his presence a proof of his adhesion to the new society, has been designed, by acclamation, an honorary member.

MAXIME CORNU

NOTES

PROF. OWEN has been appointed to a Civil Companionship of the Bath. If this is intended as an acknowledgment of Prof. Owen's services to science, it is not to the credit of Government that the honour was not conferred years ago.

PROF. TAIT'S Rede Lecture on Thermo-dynamics will be delivered to-morrow.

HITHERTO the London "Companies," whose "fatness" is notorious, have done little or nothing for the promotion of scientific researches or education. It is therefore with the greatest pleasure we record that the Fishmongers' Company have handsomely presented to Mr. W. K. Parker, F.R.S., so well known for his valuable researches on the shoulder-girdle and skull in vertebrated animals, the sum of 50*l*., in addition to an allowance of 20*l*. a year for the next three years in order to enable him to pursue such parts of his work as relate to the Anatomy of Fish. This we certainly think a step in the right direction, and the Fishmongers' Company deserve all praise for having been so original and generous as to be the first to take it. We hope their award to Mr. Parker is only an earnest of what they will do in the future, and that their example will not be lost on the other notoriously wealthy companies of the City of London. A few thousands a year would never be missed out of their enormous revenues, and would not diminish by a single dainty the sumptuousness of their numerous feasts; whereas the amount of original and practically beneficial scientific work that could be done with the money, would yield them and the country generally a rich return. We daresay those who have the management of the funds of the various companies would be willing enough to divert a portion into scientific channels if they only knew how to go about it; the example of the Fishmongers' Company may afford them a hint. Moreover they need be at no loss, for there are plenty of eminent men of science competent and judicious enough to lend advice to the companies in this matter. Commerce, with which these companies are all more or less connected, owes much of its present gigantic dimensions and great prosperity to the discoveries and advances of science; gratitude and self-interest ought to urge our London merchants not to be indifferent to scientific progress. Let us also add, that their award to Mr. Parker is on a scale which shows a very slight acquaintance on the part of the City magnates with the value of time.

A FUSION has taken place between the local committee at Munich for erecting a statue to Justus von Liebig, and the committee appointed by the German Chemical Society at Berlin; the latter, in order to insure unity of action, giving way in the question as to where the statue should find its place. Notwithstanding the serious nature of the claims of Giessen, it was generally thought that the resting-place of the great chemist would unite the majority of votes of his admirers. A considerable number of leading German statesmen and foreign ambassadors have joined the committee, the full list of which will shortly be published.

FRESENIUS, who twenty-five years ago founded a school of chemistry at Wiesbaden, has celebrated the anniversary of its foundation amidst the festive concourse of his friends and pupils, and of the Government and learned societies of his country. A gloom was unfortunately cast over this event by the death of Mrs. Fresenius, which almost coincided with its celebration.

WE regret very much to announce the death of Emanuel Deutsch, at Alexandria. His premature death is a very great loss to Eastern scholarship.

THE Alexandra Palace, under new management, reopens on Saturday. We hope the managers will not neglect the interests of science.

WE recently announced that the French Society for the Encouragement of National Industry had awarded its grand medal to Sir Charles Wheatstone. The following is an extract from the report of the Committee on the Economic Arts:—While the kaleidophone of Sir Charles Wheatstone has been the point of departure of the method which permits sounds to be studied by the aid of the eye; while his researches on the qualities of sound, on the production of vowels, while the creation of his speaking machine, have elucidated many points in the theory of the voice; while his ingenious apparatus, illustrating the propagation and the combination of waves, has facilitated the understanding of these delicate phenomena, and contributed to throw light on the mechanism of the undulatory motions, his numerous researches on the applications of electricity, in which he has shown, at the same time, profound science and a genius marvellously inspired, occupy a great place in the history of the electric telegraph. It is he who first realised, under conditions really practicable, this admirable means of communication between men and between nations, and we ought not to forget that, more than once, he has come *personally* among us to prepare its organisation and stimulate success. The unanimous choice made by the committee of the economic arts and cordially ratified by the Council honours our society as much as him who is the object of it. We are happy to give, on this occasion, a testimony of sympathy to a nation in which science is held in such high esteem. Those among us who have had the good fortune to visit the scientific

men of England in their own country have not forgotten that we have always received from them the most cordial and the most generous hospitality. In conferring on Sir Charles Wheatstone a reward rendered valuable by those who have already received it, the Council performs a pure act of justice, and acquits, at least for some among us, a debt of gratitude.

DR. VON DOLLINGER has been appointed President of the Bavarian Academy of Science and Conservator-General of Scientific Museums in Bavaria, which became vacant by the death of Baron Liebig. King Louis advised the doctor of his appointment by an autograph letter.

THE Institution of Civil Engineers hold a *conversazione* in the West Galleries of the International Exhibition, on Tuesday, the 27th inst.

MR. ARTHUR GAMGEE, M.D., F.R.S., Lecturer on Physiology at Surgeons Hall, Edinburgh, and Examiner in Forensic Medicine in the University of London, has been appointed Brackenbury Professor of Practical Physiology and Histology in Owens College, Manchester.

PROF. H. DE LACAZE-DUTHIERS, member of the French Institute, Professor of Zoology at the Faculté des Sciences of Paris, and Director of the Zoological Station of Roscoff, will accompany Commander Mouchez, in the *Narval*, that officer being engaged in completing the hydrographic map of the Algerian shores. The professor will make frequent soundings, and study the fauna of the Mediterranean. He will be assisted in the geological determinations by a distinguished young geologist, M. Vélain, Répétiteur of the Faculté of Sciences of Paris. The cruise will last five months. The ship left Lorient on May 1. M. de Lacaze-Duthiers will join them in July, at the termination of his lectures at the Faculté. Let us hope that these new explorations, under the guidance of an ardent, learned, and experienced man, will procure materials as valuable as those which were obtained by Agassiz, Wyville Thomson and others.

WE understand that there is a plan in hand for building a new museum at Vienna, to which the contents of the Imperial Zoological Cabinet, including the important collections of Natterer and other well-known naturalists, are to be transferred.

THE following telegram was received on Saturday at the Foreign-office from Colonel Stanton:—Alexandria, May 17, 1873.—The Egyptian Government has just received a despatch from the Governor-General of Southern Loudan, dated 15th March, reporting the arrival at Gondokoro of the reinforcements sent to Sir S. Baker, confirming the private intelligence recently forwarded to your lordship as to the safety of the party, and adding that in compliance with Sir S. Baker's demand, 200 soldiers, with a supply of salt and ammunition, had been sent on to him. Sir S. Baker had not reached the lake.

DR. PETERMANN has recently received a letter from Dr. Nachtigal, who in 1869 was sent out to Africa on a mission from the Emperor of Germany to the Sultan of Borneo. The letter is dated February 1872, and gives some brief details of Dr. Nachtigal's visits to the countries lying to the N.E. of Lake Tchad, the greater part of the region visited being new to European exploration. A most important discovery made by Dr. Nachtigal is that Bahr-el-Gazal, put down on some maps conjecturally as flowing into Lake Tchad, really flows out of that lake north-eastwards for about 300 miles. He has also discovered a range of mountains extending probably a distance of upwards of 800 miles from Tibesti to Darfur; one of the passes is at least 7,878 ft. above sea-level. At the date of the despatch of his letter, Dr. Nachtigal was about to undertake a journey into Bagirmi, the country lying to the south-east of Lake Tchad. It will thus be seen that this traveller is collecting materials which will add greatly to our knowledge of Central N. Africa.

A MESSAGE has been received by the *Daily Telegraph* from Mr. George Smith dated Mosul, May 19. "Since my last message," he says, "I have come upon numerous valuable inscriptions and fragments of all classes, including very curious syllabaries and bi-lingual records. Among them is a remarkable table of the penalties for neglect or infraction of the laws. But my most fortunate discovery is that of a broken tablet containing the very portion of the text which was missing from the Deluge tablet. Immense masses of earth and *débris* overlie whatever remains to be brought to light in this part of the great mound. Much time and large sums of money would be required to lay it open. I therefore await instructions from you and the Museum, as the season is closing." The *Daily Telegraph* and the British Museum have now an opportunity of showing that they have really at heart the advancement of historical research, and we are sure Mr. Smith's hint will be met by a hearty response. We feel confident that the liberality of the *Daily Telegraph* will be continued until Mr. Smith's researches are completed to his own satisfaction.

SOME time ago we were able to give authentic news of the safety of the Russian explorer of New Guinea, Dr. N. von Miklucho-Maclay, who had been reported dead in several newspapers. Dr. Maclay has himself sent a letter to Dr. Petermann, dated on board the Russian clipper, *Isumrud*, March 11, with a postscript dated Manilla, March 22, saying he is alive, though not very well, and was about to despatch to the St Petersburg Geographical Society an account of his exploration of New Guinea, his main object in visiting that country being to collect material for its ethnology. He intended to visit Luzon and the Sunda Islands, and then return to New Guinea.

AN important step has been taken in the carrying out of the decisions of the International Metric Commission which met at Paris in October last year. The form and mode of execution of the standard metre having been settled, the Commission entrusted to the French Section the manufacture and comparison of the new metres with the original standard in the Archives of France. We learn from *Les Mondes* that before proceeding to cast the definitive metres, the French Commission has thought it advisable to execute the first types, with which to test successively all the methods that will ultimately be applied to the definitive metres. This first experiment took place in the laboratory of M. H. Sainte-Claire Deville, who, with the assistance of M. Debray, has succeeded in obtaining the iridio-platinum alloy perfectly pure. The operation of casting this first international metre was considered of so much importance, that the President of the Republic and some of his Ministers, and other eminent Frenchmen, "assisted" at it. Nine kilogrammes of platinum, with one kilogramme of iridium, were melted under the action of an oxyhydrogen flame from a blow-pipe in three-quarters of an hour. The ingot was then cast, perfectly limpid, in a mould formed, like the furnace itself, of a block of carbonate of lime, whose interior walls alone were burned under the influence of the excessive temperature which was developed; consequently with this substance there is no risk of breakage. The metal was allowed to cool in the mould, and preserved its bright surface; in this condition it will be submitted to all the processes necessary to give it the definitive form which it ought to possess. The operation was considered, by all who witnessed it, as perfectly successful.

THE following further particulars with reference to the American Arctic exploring ship *Polaris*, Captain Hall, have been obtained by the correspondent of the *New York Herald*; they are dated Bay Roberts, *via* St. John's, N.F., into which the steamer *Tigress* had come, having on board nineteen survivors, including H. C. Tyson, assistant-navigator of Captain Hall's

expedition. This party, which had been landed from the *Polaris*, were driven from her by a gale which burst her moorings on October 15, 1872, in latitude 72·35. When they last saw the *Polaris* she was under steam and canvas, making for a harbour on the east side of Northumberland Island. She had no boats left of the six which she brought with her from the port of New York. Two were lost in a northern expedition, two were landed on the ice with Captain Tyson's party, one was burnt as fire-wood to make water for the crew, and the other is on board the *Tigress*. The *Polaris* was in command of Captain Buddington, who had thirteen of a crew along with him, and a plentiful stock of provisions. She was making a good deal of water, but, as Captain Tyson informed the *Herald* correspondent, she was not more leaky than when he was on board all the previous fall and winter. Her bow was somewhat damaged, and it is the opinion of the survivors they will be unable to get clear until July, and even then, if the ship is unseaworthy, they would have to make new boats to effect an escape. On October 8, 1871, in latitude 81·38, longitude 61·44, Captain Hall died of apoplexy, and was buried on shore, where they erected a wooden cross to mark his grave. He had recently returned from a northern sledge expedition, in which he had attained the latitude of 82·16. In September 1871, the *Polaris* entered winter quarters, and left August 12, 1872. The ice was very heavy, and set in a southern direction. She was forced south, and so continued drifting till Captain Tyson and party were driven from her. The sledge party crossed Kane's Polar Sea, which they pronounced to be a strait about 15 miles wide. There was an appearance of open water to the north.

The Education Department propose to send on loan, to local schools in which it will be useful, what they call Travelling Apparatus for illustrating Instruction in Naval Architecture. The following is the list of articles included under that title :—1. Model of a half-midship section of an iron-clad ship, showing the mode of forming and combining the keel, frames, beams, &c., &c. 2. Ditto of an ordinary wooden ship. 3. Block-model, showing the lines used in laying off the fore-body of a ship. 4. Ditto, after-body. 5. Diagram showing the lines used in laying-off. These models and diagram are intended to be placed in the school or class-room for reference during the hours of study, in order that the students may better understand the nature of the work under consideration, and also to aid the teachers in illustrating their ideas when imparting instruction to their classes.

Prof. Marsh, in the current number of the *American Journal of Science and Art*, describes several new species of mammalia from the tertiary deposits of the Rocky Mountains region. *Orohippus agilis* is a new species of a genus intermediate between *Anchitherium* and *Palæotherium*, which has four functional digits, the first premolar tooth nearly as large as the second, no antorbital fossa, and an incomplete bony orbit. *Colonoceras*, a new genus, nearly allied to *Hyrachyus* (Leidy) and *Helaletes* (Marsh), is peculiar in having a pair of rugosities on the nasal bones, to support dermal horns. It was about the size of a sheep. Prof. Marsh separates the genus *Dinoceras* from *Tinoceras*, on account of the maxillary horn-cores being more anteriorly situated, and the parietal crests more elevated in the former, at the same time that the canine tusks are more compressed and trenchant. A new species of *Oreodon*, and two others of *Rhinoceros*, are also described.

A *résumé* of our knowledge, strikingly incomplete as it is, on the subject of sneezing, is given by Dr. Seguin in the third number of the new and excellent *Archives of Scientific and Practical Medicine*. The author's attention was drawn to the subject from his observing a fact, previously well known, that sneezing may be frequently stopped by pressing the fingers on the lips or sides of the nose. No new theory is given to explain the physiology of the phenomenon, and it is stated that naturally most of the air expired during a sneeze escapes through the nose, but that custom has brought about the discharge of a part through the mouth. This we cannot agree with, as it is difficult to believe that custom has much influence on so abrupt an act.

We learn from *Ocean Highways* that Major Branfill, of the great Indian Trigonometrical Survey, has discovered that a peak of the Anamully Range attains a height of 8,837 ft. above the sea, 500 ft. higher than Dodabetta, in the Nilgiri Hills, hitherto supposed to be the loftiest peak in Southern India.

A few of the members of the Anthropological Institute, who did not approve of the proceedings at the annual meeting, have formed themselves into a separate society, under the name of the London Anthropological Society, with Dr. Charnock as president, and Captain R. F. Burton and Mr. Staniland Wake as vice-presidents. "This society," the prospectus says, "has been formed for the study of the science of anthropology in all its branches. The society, while adhering to the usual practice of conducting its transactions at meetings attended only by Fellows and gentlemen introduced by Fellows, contemplates placing the results of its investigations before the non-scientific portion of the community, by holding from time to time special meetings, to which the general public will be admitted."

Additions to the Brighton Aquarium during the past week :—One Alligator (*Alligator mississipiensis*), 8 feet long, from South Carolina, purchased ; one Australian Monitor (*Monitor gouldii*), purchased ; 500 salmon, Great Lake trout, common trout, and hybrid fry (*Salmo salar, lacustris, et fario*), presented by Mr. Frank Buckland ; larger and lesser Spotted Dog-fish (*Scyllium stellare et canicula*) ; Skate-toothed Shark (*Mustelus vulgaris*) ; Picked Dog-fish (*Acanthias vulgaris*) ; Monk-fish (*Rhina squatina*), one specimen 5 feet long ; Sting Ray *Trygon pastinaca*) ; Common Skate (*Raia batis*) ; Spotted Ray (*R. maculata*) ; Thornback (*R. clavata*) ; Three-spined Sticklebacks (*Gasterosteus spinulosus*) ; Bass (*Labrax lupus*) ; Streaked Gurnards (*Trigla lineata*) ; the Piper (*Trigla lyra*) ; Greater Weever (*Trachinus draco*) ; Lesser do. (*T. vipera*) ; John Dorée (*Zeus faber*) ; Dragonets (*Callionymus lyra*) ; Land Smelts (*Atherina presbyter*) ; Grey Mullet (*Mugil capito*) ; Carp (*Cyprinus carpio*) ; Roach (*Leuciscus rutilus*) ; Minnow (*L. phoxinus*) ; Loach (*Nemachilus barbatula*) ; Tench (*Tinca vulgaris*) ; Herring (*Clupea harengus*) ; Sharp-nosed Eel (*Anguilla vulgaris*) ; Greater Pipe-fish *Syngnathus acus*) ; Snake Pipe-fish (*Nerophis æquoreus*) ; Branched Seahorse (*Hippocampus ramulosus*), Mediterranean ; Squids, (*Loligo media*) ; Masked crabs (*Corystes cassivelaunus*) ; Spider Crabs (*Maia squinado*).

The additions to the Zoological Society's Gardens during the past week include a Cashmere Monkey (*Macacus pelops*), presented by Rear-Admiral Davies ; a Savannah Deer (*Cervus savannarum*) from South America, presented by Capt. Bennett ; a Suricate (*Suricata zenik*) from South Africa, presented by Mr. A. Benyon ; a Palm Squirrel (*Sciurus palmarum*) from India, presented by Mr. W. Lovegrove ; a Mocking Bird (*Mimus polyglottis*) from North America, presented by Mr. P. Frank ; an Indian Eryx (*Eryx johnii*), presented by Dr. Anderson ; two pied Crow Shrikes (*Strepera graculina*) from Australia ; an Ursine Colobus (*Colobus polycomus*) from Sierra Leone ; a Hocheur Monkey (*Cercopithecus nictitans*) from West Africa ; a Wandering Tree-pie (*Dendrocitta vagabunda*), two pied Mynahs (*Sternopastor contra*), and two rose-coloured Pastors (*Pastor roseus*) from India, purchased ; two Hoffmann's Sloths (*Cholopus hoffmannii*) from Panama ; two black Vultures (*Cathartes atratus*) from South America ; a black-handed Spider Monkey (*Ateles melanochir*) from Central America, and a Crocodile (*Crocodilus americanus*) from Mexico, deposited.

COMPARISON OF THE SPECTRA OF THE LIMB AND OF THE CENTRE OF THE SUN *

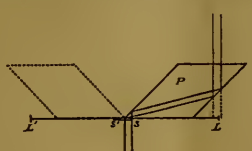
A COMPARISON of the spectrum of the edge of the sun with that of its centre is of great theoretical interest; but any comparison other than by direct juxtaposition must be very unsatisfactory, and the more so as the differences are less. In order to obtain spectra of two different portions of the sun side by side, where the slightest variations may be detected, I have constructed a small prism with four polished sides, its bases being parallelograms. This is so placed that one face rests upon the slit plate of the telespectroscope, and has its acute edge perpendicular to the slit at its middle point. The instrument may then be directed so that the image of the sun falls with its centre on the uncovered portion of the slit, while the light which forms the edge of the sun, falling perpendicularly upon the first surface of the prism, suffers two interior total reflections and a displacement depending upon the form of the prism. A glance at the figure, in which $s\,s'$ is the slit, L L′ the diameter of the sun's image, and P the prism, shows that no light from the covered part of the slit will reach the collimating lens except that which has been reflected from the two sides of the prism. The relation of the acute angle (v) and the distance between the reflecting sides (t) to the focal length of the great telescope (F) and the width of the spectrum (a) is given by the formula,

$$2t \sin v = F \tan 16' - a.$$

The sides of the prism not fixed by the equation admit of considerable latitude, but should be made to approach the lower limit in order that the planes of the direct and transmitted images may be as little separated as possible. Of course t and v should be so proportioned that the reflections may be total.

The instruments with which the following observations have been made are those belonging to the observatory of the Sheffield (U.S.) Scientific School, consisting of an equatorial telescope of 9 in. aperture, and 118 in. focal length, by Clark, and a spectroscope of Young's form by the same maker. The spectroscope has a dispersive power of 12 prisms of 60°. In most of these observations an eye-piece of high power has been adapted to it, which gives a separation of the D lines equal to 64 minutes nearly. In the small prism placed before the slit, a is equal to ·04 in., a quarter of the length of the slit.

When the instrument is properly directed and in adjustment, we see a very narrow black line dividing the spectrum longitudinally into two parts of widely different intensity; the fainter,



belonging to the limb of the sun, is marked on its edge by the bright chromosphere lines. Upon comparing these two spectra, certain differences are recognised besides that of intensity, by far the most marked of which are exhibited by the lines b_1 and b_2, which become sharper and less hazy near the limb. The line b_3 possesses the same characteristic, but to a less degree; C and F also become sharper in the same region. Excepting these and the D lines it requires very close examination to detect any variation. There is, however, a line in the red at 768·1 of Kirchhoff's scale which is strongly marked near the centre of the sun's disc, but disappears entirely, to my power at least, within 16″ to 20″ from the limb. Two other lines below F, at 1828·6 and 1830·9 of the same scale, exhibit nearly complementary phenomena, *i.e.*, they are strongly marked near the edge, but much fainter at the centre. These latter lines also become greatly strengthened over the penumbræ of spots. The line 768·1 is not thus affected. These are all the differences which I have invariably seen in repeated examinations since February 17.

Others have, however, been suspected. Certain lines, which are strengthened in a region of spots like those above mentioned, appear to be strengthened also near the edge, but do not undergo so marked a change. It is obvious that the differences should be most pronounced in the clearest sky, and such is the case. The closest examination has extended only from B to a short distance above F, as the plate glass of which the small prism is made has a decided yellow tint and absorbs the blue rays strongly.

Since the light from the border of the sun undergoes a general absorption, which reduces its intensity to much less than one-fourth that at the centre, according to Secchi's measurements, and yet the spectroscopic character is changed so slightly, it is impossible for me to escape the conviction that the seat of the selective absorption, which produces the Fraunhofer lines, is below the envelope which exerts the general absorption. But the phenomena of the faculæ prove not only that this envelope rests upon the photosphere, but also that it is very thin. The origin of the Fraunhofer lines, then, must be in the photosphere itself, which is in accordance with Lockyer's views.

Any effects which the chromosphere might produce, we would anticipate finding most evident in the lines of those gases which are readily detected there. A reference to the observations shows at once a compliance with this anticipation in the lines of hydrogen, magnesium, and sodium. The line 768·1 is not less strikingly in concordance, if it be regarded as 768·?* (the ? indicates doubt as to the tenths of the scale, and * absence of a corresponding black line) of Young's Catalogue of Chromosphere Lines. The lines 1828·6 and 1830·9, with others of the same class, probably have their origin in the medium which exerts the general absorption, and thus are allied to our telluric lines. It also seems probable that the chromosphere is too transparent to reverse many of its lines. That this is the case in the helium lines is tolerably certain.

In the apparatus described, two similar prisms were also placed over the slit in a symmetrical position. The spectra of two opposite edges of the sun were thus brought together, and the change in refrangibility due to the sun's rotation was very clearly shown. CHAS H. HASTINGS

Newhaven, April 3

* Made at the Sheffield (U.S.) Scientific School. Communicated by Prof. Newton.

THE "INSTINCT" QUESTION

FROM the many additional communications we have received on this subject, we make the following selection.

With regard to a sense of direction, Mr. George C. Merrill, of Topeka, Kansas, writes as follows:—

I have learned from the hunters and guides who spend their lives on the plains and mountains west of us, that no matter how far or with what turns they may have been led in chasing the bison or other game, they on their return to camp always take a straight line. In explanation they say that unconsciously to themselves they have kept all the turns in their mind.

Mr. C. Bygrave Wharton, of Bushey, Herts, writes:—

As a left-handed and left-legged man who has more than once been lost in the bush in New South Wales, my experience may possibly be of interest to Mr. George Darwin and others. Invariably I unintentionally bore to the left; and once, after wandering for about six hours, just as I was giving myself up for lost, I discovered that I was within a hundred yards of the place from which I had started having performed a large circle to the left. It will thus be seen that though my left leg and arm are the stronger, there is always a tendency to walk in a circle to the left.

Mr. William Earley, of the Gardens, Valentines, sends the following interesting observations on the habits of wild rabbits:—

As is well known, the doe rabbit does not produce her young in any ordinary rabbit warren, or "run," but invariably selects a quiet out-of-the-way situation wherein to form a nursery for them. Now the reason for this peculiar practice has always been attributed to the fact that they leave their legitimate homes at this all-important period, simply because the male parents invariably destroy the offspring if an attempt be made to breed them in the permanent home or warren. I incline to believe we must look elsewhere for the explanation.

Firstly, then, a close atmosphere seems all-important to their development, as the old doe rabbit not alone denudes her breast of its natural fur covering wherein to ensconce them warmly all

around, she also closes up the usual entrance to the nursery firmly, even patting the soil down to exclude the colder outer air. In due time, as the young increase in size, &c., she makes "air-holes," commencing with very minute ones, which are gradually enlarged as the inmates gain strength and size.

These are known facts, to which I add one not heretofore noticed, which seems important; it has reference to the formation of the subterranean nursery, in regard to its shape and the evident "end in view." These minor tunnels, or nursery "stops," are invariably formed by starting a downward curve, at an angle of about 45°, which is continued beyond any line of sight the eye can be guided by on the outer side. They subsequently curve abruptly upward, with almost double this initial acuteness, ending in a shelved enlargement, with the roof boundary nearly uniformly three inches from the surface of the ground above and without.

What I feel constrained to uphold in regard to these first facts is, that herein exists a most subtle sanitary arrangement; that by these means a subdued genial air is admitted, the only fresh air the nursery receives, and whereon the nurselings thrive, strengthen, and grow. The facts would seem to support the theory that the mother-parent continues what must be its hard work—doubly hard and severe in these finishing overhead excavations—until the very keen power of scent they possess assures them that the outer air is slightly admitted through innumerable interstices in the soil above.

My second proposition, or indeed belief, based upon distinct observation, is, that the parent doe rabbit does not visit its young, even nocturnally, at certain times oftener than once in each 72 hours! Certainly sometimes not more frequently than once during the 48 hours comprising two days and two nights. The latter fact I have ascertained by carefully marking and observing the neatly closed entrance to the stops, and also by marks beneath an iron garden-gate, in freshly laid gravel, which the rabbits had to scratch aside before they could enter. Furthermore, I have every reason to believe that the parent rabbit ceases to transmit the customary natural scent at the time she approaches or acts about the "stop;" if, indeed, as is the case with some kinds of game birds, during the period of incubation, she does not lose it altogether. Certain is it no appreciable amount of scent remains about the stop in the early morning after the parent rabbit has visited its nursery during the past night.

[On the question whether animals have the power of ceasing to emit a scent at certain times, see the article on Pheasants in this week's number.—Ed.]

Mr. J. D. Bell, of the *World* office, New York, writes as follows on the consciousness of time in horses:—

My own experience will not allow me to speak positively as to smell, but horses that I have met and carefully observed, were not peculiarly gifted in this respect. It was a common saying on "the plains" and in the mining regions of California, that mules, by the way very sagacious animals, which would well repay observation, "scent the redskin a mile away." I have made some inquiry on this point, but have been unable to find that the olfactories of the mule are really thus acute. I can bear testimony to the extraordinary powers of sight in horses. And I am inclined to think that they take more notes by the way through their eyes than through the nose. As none of your correspondents have called attention to it, I desire to recall the fact that horses have ears as well as eyes and noses. Their hearing is very acute, and I am inclined to think that the explanation of the detection of red-skins by mules, will be found in the educated ear rather than in the educated nose. It used to be said in the cavalry service of the United States during the war that "horses were the best pickets." I have seen them again and again in the dead of night prick up their ears when the men on their backs heard nothing. I have never seen them sniff or smell first. Listening was invariably the first movement. Then came sight. Horses have scanned the woods and chapparall with a care that no man could surpass. If the moving thing first heard and then seen was an unfamiliar object—more especially if it was moving along the ground—then I have seen horses sniff, smell, and snort. In horses the snort is expressive of aversion rather than fear, or perhaps of a sentiment compounded of both.

Horses learn the notes of the bugle, and I have often seen a trained horse turn in a direction opposed to that indicated by the pressure of his less experienced rider's leg. I have known horses which, after detecting the presence of moving objects by hearing and then by sight, during which time they remained perfectly quiet, change feet, and even paw the ground if the rider did not by his movement show recognition of the presence of what might be an enemy.

And what, it will be asked, has this to do with the question at issue? Simply this—horses think, horses reason, horses classify, horses remember. But I desire to offer a few remarks on Darwin's letter about the blind mare that stopped at every public-house on the road. My own explanation of the fact, and there must be hundreds of similar instances—is that the mare, by long-continued custom, became conscious of the time which should elapse between the respective stopping places. Horses have a great memory for time. What is the interpretation of the existence and improvements of our racing and trotting horses but that these animals have the power of remembering time, and the power of transmitting this improved registering and transmitting cerebral apparatus to their progeny. I will close this letter by relating a couple of incidents. I was speaking of my belief in this equine memory for time to an enthusiastic horseman of my acquaintance, the other day, and at the same time showed him Mr. Darwin's letter. He said that in his youth he had driven a horse, sound in every respect, on a "bread" route. He always served his customers in a certain order. After a while his animal knew all the places, and stopped in front of the store or residence where bread was to be delivered, without a signal from his master. If the master remained in any place longer than usual, his horse started off, but instead of going to the next customer, returned to the stable. This, said he, occurred again and again, not at one place, but at many places.

I served, during the recent war, in a cavalry regiment in the United States' service. The horses knew the time for "the relief," and if the relief did not come they became restive. On one occasion we changed the time of remaining on post from two to four hours. For the first two hours the horses behaved admirably; after that they were in constant motion, and had to be constantly restrained. Horses recognised the time for stable call—not merely "hunger"-call, but the proper time-call.

A gentleman in the north of Ireland, who gives us his name and address, sends us the following story of a dog:—

He was a terrier—a cross upon the skye—very intelligent, like all of his kind. He was given to me by Mr. C——, a gentleman residing upon Lough Foyle near Moville. He was brought from that to Derry in a steamer up the Lough, and from Derry to Buncrana down Lough Swilly by train. He therefore travelled two sides of an acute-angled triangle, about thirty miles in all by conveyance. The third side being about fifteen miles, but a mountainous and unfrequented route. He appeared at first very happy and reconciled, but one fine morning he was seen taking the road parallel to the railway back to Derry, and after my searching for him for some days and making every inquiry, we found he had returned, tired and worn out, to his old master, Mr. C., near Moville. It was evidently hard work, and he was two or three days on the road. This I consider an interesting case.—Here the dog did not go by the third side of the triangle—which if he knew how to do he would have done instead of exhausting himself by the long route he took—following the direction along which he came by steamer and train.

My theory is that the dog does preserve a very distinct, or at least tolerably distinct, notion of the route he was brought from home by, and that it is forcibly impressed upon him; but the great aid to his return is the *direction* of the sun or light. He knows that if he travels in a certain direction—say E.—he is going towards the morning sun, and W., towards the evening sun.

A correspondent, Mr. R. A. Pryor, Hatfield, sends us the following extract from the Rev. A. l'Estrange's edition of Miss Mitford's "Life and Letters":—

Miss Mitford (Letter of October 16, 1829, vol. ii. p. 277), had been dining in company with the late Dr. Routh, president of Magdalen College, Oxford, who "had a spaniel of king Charles's breed, who, losing his mamma by accident when a pup, was brought up by a cat: well, he and his brother, for there were two pups, orphans of three days old, were nursed by this

cat. But what I mention him to you for is to tell you the curious account which the doctor, a man of perfect veracity, gives of his habits—he is as afraid of rain as his foster mother, will never, if possible to avoid it, set his paw in a wet place; licks his feet two or three times a day, for the purpose of washing his face, which operation he performs in the true cattish position, sitting upon his tail; will watch a mouse-hole for hours together; and has in short all the ways, manners, habits, and dispositions of his wet nurse, the cat. Is not this very singular? But it's puzzling as well as amusing, and opens a new and strange view into that mysterious subject, the instincts of animals. Mrs. Routh, and Mrs. Blagrove (the mistress of the cat, who was present at dinner to-day), confirmed all the facts of the case. They say that one can hardly imagine how like a cat Romulus (the dog's name) is, unless one lived with him."

The following is from a letter of October 20, 1835:—

"Another characteristic of this hot dry summer (1835) has been the manner in which the large humble bees have forced open, torn apart the buds of my geraniums; an operation I never saw them perform before.

"Another novelty of this season has been that the splendid new annual, the *Salpiglossis picta*, has, after the first crop of blossoms, produced perfect seed without flower petals, a proof (if any were needed), that the petals which constitute the beauty of a flower, are not necessary to its propagation."

We may mention that Mr. C. H. Jeens has a cat and a dog, the latter now twenty months old, which, from the time the dog was a month old, have been in a relation similar to the cat and the pups in Miss Mitford's story, with a result somewhat similar. When the dog catches a mouse he treats it after the well-known manner of cats, pawing it, allowing it to run a distance, then pouncing upon it, and so on for many minutes.

SCIENTIFIC SERIALS

The *Monthly Microscopical Journal* commences with the paper on "a new Callidina; with the results of experiments on the Desiccation of Rotifera," by Mr. H. Davis, which was read before the Royal Microscopical Society in April, and in which the author, by means of several carefully performed experiments, proves that Rotifera, which survive after being exposed to a temperature of 200° F., or in a vacuum for some time, do not get desiccated, but only covered with an impervious gelatinous covering which retains a certain amount of moisture in them. This Mr. Slack shows to have been previously proved. Mr. Parfitt describes a new form apparently related to the Rotifera and the Annelida, named by him *Ageihisteus plumosus*, with the oral aperture lateral and inferior. Dr. Braithwaite describes *Sphagnum papillosum* and *S. austini* in his paper on Bog Mosses; and Mr. F. Wenham has another valuable paper on "Binoculars for the highest powers." A new slide for the microscope, designed

by Mr. D. S. Holman, is described. It is a current cel or moist chamber for studying the blood and other organic fluids. The accompanying illustration will assist in explaining it. Two shallow circular cavities are excavated in a very flat thick glass slide, not far from one another. They are united by two or three grooves, which are cut as triangles in order that they may be of unequal depth in different parts. When the apparatus is to be used, each of the shallow cavities and the intermediate grooves are partly filled with the fluid to be examined, after the slide has been warmed by the hand, and a glass cover is laid over the whole, which soon becomes fixed from the cooling of the slide and the consequent rarification of the enclosed air. The grooves between the cavities form the field for inspection, and any degree of movement may be produced in the fluid which they contain by approaching the warm finger to the top of one of the cavities, as the air inside is thus made to expand and drive some of the fluid into the other which is not heated. There is scarcely any limit to the degree of delicacy of movement which may be attained with this instrument; the slightest movement, not sufficient to remove a body from the field of vision, being produced without difficulty after some practice.

SOCIETIES AND ACADEMIES

London

Chemical Society, May 15.—Dr. Odling, F.R.S., president, in the chair.—Dr. H. S. Armstrong delivered a most able and comprehensive lecture on "Isomerism," pointing out that the generally received position theory was incompetent to explain many reactions which took place in the formation of metameric and isomeric substances. He suggested that the investigation of the thermal properties of compounds would establish facts which might ultimately enable us to obtain some insight into the matter.

Anthropological Institute, May 20.—Prof. Busk, F.R.S., in the chair.—A paper was read by Mr. Hyde Clarke on the Egyptian Colony and Language in the Caucasus. This was devoted to a part of a series of investigations to ascertain the comparative chronology of prehistoric races by the correlation of comparative philology with the study of physical features, monuments, weapons, &c. It identified the Ude language of the Caucasus, that of an expiring population, with the Coptic, and still more closely with the Hieroglyphic in minute and numerous details of roots, grammar, and structure. The resemblance of the Bzyb dialect of Ude with the Bashmurie Coptic illustrated the differences between Hieroglyphic and Coptic. The paper then proceeded to point out the conformity of strata in the linguistic topography of Caucasia and the Nile regions, particularly in the earlier epochs of Agaw and Abkhas, and of Furian and Akush. Hence the conclusion was drawn that the sources of Egyptian grammar were not in the late Semitic, but in the prior epochs, and that Egyptian grammar and civilisation belong to a remote period in the annals of civilisation, but still to a relatively modern period in the history of man. The author, accepting the history of Herodotus as to the conformity between the Colchians of Caucasia and the Egyptians, did not accept his theory that the Colchians were a colony of Lesodites. In the time of Herodotus and Pindar, the Colchians, now light, were as dark as the Egyptians.

Glasgow

Geological Society, April 24.—Mr. John Young, vice-president, in the chair.—Mr. David Robertson, F.G.S., read a note on the "Precipitation of Clay in Fresh and Sea Water." He stated that in making some observations on the gradual deposition of particles of clay held in solution by water, he found that in fresh water these were held suspended for a long time before wholly subsiding, while salt water, or a mixture of salt and fresh, became comparatively clear in the course of a few hours. The results showed that water only slightly brackish had a great power in precipitating the clay, and from this he concluded that the great bulk of the clay carried down in solution by rivers must be deposited before it could reach any great distance from the sea shore. This might throw some light on the formation of deltas, and on the silting up of river courses within the influence of the tides. It might also assist in determining how far the glacial mud, for example, could be carried into the sea by tides and currents.—The chairman read a paper which he had prepared in conjunction with Mr. Robertson, "On the Composition of the Boulder and Laminated Brick Clays of the West of Scotland." The authors stated that their object was to ascertain, if possible, the conditions under which these clays had been deposited, and how far any of them were fossiliferous. For this purpose they had collected samples of clays from upwards of fifty localities. These, after being dried, were weighed, and then carefully washed. The results led them to regard as most probable the conclusion that the till or unstratified boulder clay was a deposit that had been laid down in water and formed from materials which land ice had carried seawards, the ice extending over the submerged tracts now covered by the boulder clay. This seemed to be borne out by the large percentage of fine glacier

mud found in all the boulder clays, and which they thought could not have been retained in the deposit had it been formed under a sheet of land ice above sea level, seeing that streams of muddy water continually issue from under all existing ice sheets. The laminated brick clays they viewed as having been formed by rewashings out of the boulder clay, and from the flow seawards of the muddy water from under the melting ice-sheets that bound the shores; the sea, however, being then comparatively free of ice. In nearly all the brick clays of the maritime districts they had found organisms, chiefly marine; but a few indicated brackish and fresh water conditions. Only in one or two instances had they found organisms in the boulder clay.

Berlin

German Chemical Society, May 12.—President, A. W. Hoffmann. C. Engler spoke on the simultaneous action o ammonia and phosphoric anhydride on ketones, especially on acetophenone, C_8H_8O. The results are two bodies, $NC_{24}H_{18}$ and a hydrocarbon. The former crystalline, and a weak base is formed according to the formulæ,

$$2C_8H_8O + NH_3 - 3U_2O = NC_{24}H_{21}$$
$$2NC_{24}H_{21} + 3O = 2NC_{24}H_{18}.$$

The hydrocarbon simultaneously formed is beautifully crystallised triphenylated benzol, $C_6H_3(C_6H_5)_3 = C_{24}H_{18}$. The reaction corresponds therefore to the formation of mesityline from acetone. Phosphoric anhydride and aniline seem to transform acetone into a base of the formula $CH_3 (C = NC_6H_5) - CH_3$ a liquid boiling between 210° – 220°.—C. Rammelsberg has investigated a so-called ozone-water, an article of trade, much advertised and praised for its medical properties. He has found no trace of ozone, but a small proportion of chlorine in it. Pursuing his researches, he found water of ordinary temperatures unable to absorb ozone without the application of pressure. The ozone was produced by Siemen's tube. Referring to a popular error: he explains what is generally considered as the production of ozone by mixing potassic permanganate with sulphuric acid, by the unavoidable presence of potassicperchlorate.—C. Scheibler referred to a gum, $C_{12}H_{22}O_{11}$ (isomeric with arabine) which he found in beetroot, and which is identical with metapectic acid. It occurs in two modifications turning the plane of polarisation to the right or to the lett. The latter is transformed by sulphuric acid into "arabin sugar" identical with the sugar he obtained by the same process from arabine. Both crystallise in identical rhombic prisms, turn the plane of polarisation to the right ($\alpha =\ \ + 116$), reduce solutions of copper, and do not ferment.—N. Michaelis has made the interesting discovery that a liquid phenylic phosphide is obtained by passing benzole and tercloride of phosphorus through red hot tubes. It corresponds to the formula, $C_6H_5.\ P.\ Cl_2$, and boils at 222°.—A. Brückner, comparing two various mononitrophenoles, has found erroneous the supposition that there are four bodies of this formula, which he has reduced to three.—N. Baumgarten refutes the generally adopted opinion that bromine replaces chlorine in chloric acid. His experiments corroborate the doubt expressed by J. Thomson, and founded on his thermochemical researches.—C. Schorlemmer continued his valuable communications on hephylic acids and alcohols, as derived from heptan and from œnenthol.—V. Meyer recommends, for analysing commercial chloral, to heat it with a certain quantity of potassa of known strength, and to determine volumetrically the quantity of potassa that remained uncombined with formic acid.

Paris

Academy of Sciences, May 12.—M. de Quatrefages, president, in the chair.—The following papers were read:—On the portative force of magnets, by M. Jamin. The author thus denominates the carrying power of magnets. He exhibited two: an ordinary one weighing 6 and carrying 80 kilos, and one made on his principle, weighing 600 grammes and carrying 500 kilos; the paper described their construction.—On the causes which produce the tumefaction of obsidian at a high temperature, by MM. Boussingauld and Damour.—New researches on aldol, by M. Ad. Wurtz. The author thus names a condensed aldehyde partaking of the properties of that body and of an alcohol.—Hydrologic studies of the Seine, by M. Belgrand.—The Academy then proceeded to elect a member of the physical section in the place of the late M. Babinet. M. P. Desains obtained 32; M. Cornu, 13; M. Le Roux, 7; and MM. Bourget, Gaugain, and Lucas 1 vote each. M. Desains was therefore declared duly elected.—A report on MM. Troost and Hautefeuille's paper on isomeric and allotropic transformations was then read, and also one on a memoir on the proximate analysis of rocks, &c., by M. Fouqué.—On the water supply of Versailles during the first half of 1873, by M. E. Decaisne.—On the algebraic representation of bright lines in space, by Mr. W. Spottiswoode.—On the regulation of compasses, by M. Caspari.—On an electro-diapason of continuous movement, by M. E. Mercadier.—An answer to an observation of M. Raynaud on the conditions of maximum resistance in galvanometers, by M. Th. du Moncel.—Observations on the notes of MM. du Moncel and Thenard on the decomposition of carbonic anhydride by the silent electric discharge, by M. G. Jean.—Observations on a paper by M. du Moncel on the condensed induction spark, by M. Houzeau.—On the action of sulphur on arsenic, by M. Angélis.—On the action of gaseous hydochloric acid on the compound ammonias, by M. Ch. Lauth.—On a modification of the optical saccharimeter, by M. Prazmowski.—On the action of the dissolved oxygen of water on reducing agents, by MM. Schützenberger and Risler.—A new classification of the fresh-water algæ of the genus *Batrachospermum*, by M. Siroclot.—On spring and winter frosts, by M. Martha-Beker.

DIARY

THURSDAY, May 22.

Society of Antiquaries, at 8.30.—Miscellaneous Antiquities.
Royal Institution, at 3.—Light: Prof. Tyndall.

FRIDAY, May 23.

Royal Institution, at 9.—Spectra of Polarised Light: Mr. Spottiswoode.
Geologists' Association.—Excursion to Eastbourne and St. Leonards.

SATURDAY, May 24.

Royal Institution, at 3.—The Historical Method: John Morley.
Linnean Society, at 3.—Anniversary.

MONDAY, May 26.

Geographical Society, at 1.—Anniversary.

TUESDAY, May 27.

Institution of Civil Engineers, at 9.—Conversazione.
Royal Institution, at 3.—Archæology of Rome: J. H. Parker.

WEDNESDAY, May 28.

Society of Arts, at 8.
Geological Society, at 8.—On the Glaciation of the Northern part of the Lake District: J. Clifton Ward.—Alluvial and Lacustrine Deposits and Glacial Records of the Upper Indus Basin: Frederic Drew.—On the Nature and probable Origin of the superficial Deposits in the Valleys and Deserts of Central Persia: W. T. Blanford.—On the Cephalopoda Bed and the Oolite Sands of Dorset and part of Somerset: James Buckman.
Archæological Association, at 8.

PAMPHLETS RECEIVED

English.—The Method of Quantitative Induction in Physical Science: Dr. G. Hinrichs.—Two Essays drawn up for the Official Record of the Exhibition held in Melbourne, 1872–3. 1. On Preserved Meats. 2. On Colonial Wines: Rev. J. I. Bleasdale, Melbourne.—Solar Radiation: an Account of the Experiments made at Harpenden, Herts, by the Rev. F. W. Stow, M.A.—Report of the Entomological Society of Ontario, 1872.—The Geological Survey of Canada, Report of Progress for 1871–2.—The Fourth Annual Report of the State Board of Health of Massachusetts, January, 1873.—Journal of the Royal Agricultural Society of England, Pt. 1, No. 17, Vol. x. (Murray).—Local Biology: Rev. L. Blomfield (Bath).—Report of the Committee on the Treatment and Utilisation of Sewage, 1871 (Taylor and Francis)

THE ZOOLOGICAL STATION AT NAPLES

ROME was not built in a day, says the proverb,—and so far, at least, the Zoological Station resembles the Eternal City,—for it is not yet quite finished.

The difficulties have been sufficient to explain this delay. The complexity of a building of this kind, which had to combine so many technical arrangements with scientific requirements without neglecting beauty of appearance and the comfort of a dwelling-house for the principal, assistant naturalists, and other officials, will easily be conceived by those who have ever attempted to carry out the plan of an establishment *sui generis.* Add to this, that the dimensions of the building were limited before a stone was laid, that the sums allotted for the construction were by no means unlimited, that all had to be done in so difficult a place as Naples, by a foreigner who never had experience in practical pursuits of this intricate nature, but is a naturalist, and not a business man.

At the same time, one must not believe that this delay has been altogether a misfortune. Though the Zoological Station had to pass through more than one "crisis," it has been particularly lucky: dangerous as the aspect of all these critical situations seemed, nevertheless it has always escaped, and now finds itself in better circumstances than it would have been without them. This seems principally due to the fact that in struggling against difficulties and enemies, one is forced to strengthen and augment one's auxiliary troops, and thus the army of supporters gets greater and greater, and triumph is more easily secured than before.

As the outlay had been considerably increased in consequence of greater dimensions, and some internal arrangements, it became necessary to find additional funds. I am happy to say, that on my application, the German Empire, after having consulted the Berlin Academy of Sciences, consented to contribute 1,500*l.* The Italian Government likewise promised, on my personal application to the Minister of Finances, Dr. Sella, to remit the not unimportant sums that had to be paid as duties on the importation of the machinery and the great glasses.

On the other hand, I formed a new scheme for keeping up the establishment. Some of the readers of NATURE may remember, perhaps, that the whole place was founded upon the income of the Aquarium, which is combined with the Zoological Station. The bulk of the capital being augmented, and the whole establishment in all its parts increased, the sums necessary for supporting it likewise must increase. Instead of ten places to be given to foreign naturalists, who come to work in the Zoological Station, there are now twenty. The number of officials, scientific and unscientific, will increase at the same rate, and everything else, too. Desirable as such an event must be for science' sake, much as it would increase the importance of the new Institution, there can be no doubt that it would also greatly increase its annual wants.

I pursued, therefore, as much as I could, the plan for letting the tables in the laboratories,—a plan which has been spoken of in NATURE (vol. vi. p. 362). I am happy to say that at present Italy as well as Prussia has consented to hire each two tables. Bavaria, too, is likely to take one table, and further applications have been made to Saxony, to Baden, and some other places, which at present cannot be indicated, as negociations are still impending.

The Library of the Station has made very important progress. The Zoological Society of London has generously granted the complete set of their Proceedings; the British Association the complete set of their Transactions. Dr. Engelmann, the Leipzig publisher, has again made a splendid gift of all that he has published since 1870; Viet and Co., of Leipzig, have given the eight last volumes of the *Archiv für Anatomie und Physiologie*: Friedlander, of Berlin, has sent some of his most valuable books; and single naturalists constantly send in their publications. The Catalogue of the whole Library will soon appear, and be delivered to the scientific public as Appendix to the *Zeitschrift für wissenschaftliche Zoologie.*

The Station has already made its presence felt in the world of Zoology, by sending to Universities and Laboratories collections of Mediterranean animals. What makes this especially valuable is, that by the careful way in which the required specimens have been prepared and preserved, they are always capable of being dissected and even studied in a histological way, which seldom is the case with museum specimens. Thus the Universities of Marburg, Göttingen, Munich, Strasburg, Jena, and others, have received such collections as were asked for by the Professors of Zoology; besides this, the zoologists that passed during the last winter to Naples or Messina, have been always assisted by the scientific staff of the Station.

We have also succeeded in sending animals alive to distant places. Thus it has become very generally known that a small parcel containing some specimens of Amphioxus has been received as a charged letter in the Crystal Palace Aquarium; and I hear from Mr. Lloyd that the small animals are still alive. We succeeded also in sending some large crabs over by steamer.

It is my intention to develop as much as may be this department of the activity of the Station, and I take this opportunity of stating that the Station will send Mediterranean animals of every kind and in any state of preparation to those who make application for them. The charges will be as moderate as possible, always in accordance with the self-supporting principle, so as to enable every part of the establishment to provide for its own wants.

ANTON DOHRN

Naples, May 8

GAUDIN'S "WORLD OF ATOMS"

L'Architecture du Monde des Atomes, devoilant la structure des composés chimiques et leur cristallogénie. Par Marc-Antoine Gaudin. (Paris: Gauthier-Villars, 1873.)

IT is now more than forty years since Ampère, in his lectures at the Collége de France, was discussing the evidence in favour of the existence of atoms, and the difficulties of any scientific investigation of their properties and relations. M. Gaudin, one of his hearers, was struck,

as he tells us, with the importance of this investigation, and then and there devoted the efforts of his whole life to carry it out. Accordingly, in 1832 he presented a very extensive work to the Academy of Sciences, a report on which, by MM. Gay-Lussac and Becquerel, is annexed to the volume before us.

The ideas developed in this work were derived from two sources—crystallography and chemistry. Haüy had endeavoured to explain the regularity of the forms of crystals by regarding them as built up of molecules, the form of each molecule being similar to that of the simplest solid which can be obtained from the crystal by cleavage. The absolute size of these integrant molecules, as they were called, was left, of course, indeterminate.

Wollaston preferred to regard the arrangement of the ultimate molecules in a crystal as resulting, not from their accurately fitting one another as bricks do in a wall, but from their tendency to crowd together into the smallest possible volume as peas do in a bag. The form of the molecules, according to Wollaston, was not polygonal, but spherical or ellipsoidal.

At this point Ampère took up the theory. His atoms were no longer either closely fitted together, or even touching one another at isolated points, but were maintained by attractive and repulsive forces at distances exceedingly great compared with their own dimensions. The forms of the atoms themselves were therefore no longer considered as of any importance; the molecules, formed of groups of these atoms, were represented in diagrams as systems of points; and the explanation of the geometrical properties of the substance in the crystalline form was sought in the geometrical arrangement of these atoms.

The proportions in which the atoms of different kinds were to be represented in the molecules were determined in accordance with the atomic theory of chemistry, established by Dalton, and the absolute number of such atoms in the molecule was arranged so as to satisfy the law of gases, recently discovered by Gay Lussac, which asserts that the mass of every gaseous molecule is proportional to the specific gravity of the gas at the standard pressure and temperature.

The theory of M. Gaudin may be regarded as founded upon that of Ampère, with certain modifications. Instead of assuming with Ampère, that when two molecules combine, the form of the compound molecule is the resultant of the forms of its components, he supposes that the atoms of the combining molecules are all thrown into a common stock, to be arranged, according to some principle of equilibrium or of symmetry, in a form having no necessary relation to the forms of the combining molecules.

In the work before us M. Gaudin gives us, as the result of his long-continued meditation on compound molecules, actual diagrams of their supposed forms, showing not only their outward shape, but the arrangement of the molecules in each of the layers in which they are disposed. The ingenuity with which he has arranged in a symmetrical manner groups sometimes amounting to 279 atoms must be seen in order to be appreciated. But the merit of these arrangements as an explanation of facts must be tested, first by a careful comparison of those forms whose chemical relations are similar, and then by a comparison of each diagram with the crystallographic properties of the substance which it is supposed to represent. The author has, to the best of his ability, applied both these tests, and we shall not here pronounce sentence upon the result of such an examination.

We may remark, however, that M. Gaudin began his labours forty years ago, using the methods of investigation which we have briefly described. Since that time he has been patiently arranging his atoms by rows and groups, and representing them in models by means of pearls of various hues. He has shown no symptom of being attracted towards any of those newer paths which Joule, Clausius, and others have opened up into the higher regions of kinetic molecular science. Indeed we not only find no mention of the names of any of these men, but we look in vain for any indication of a desire to pass beyond mere geometrical arrangements of atoms, and to inquire into the forces with which they act on each other or the motions with which they are agitated. There is a chapter, indeed, entitled "Hémiédrie et pouvoir rotatoire," but though there is something about hemihedry, there is nothing there at all about the power of rotating the plane of polarisation of light. The only piece of dynamics in the book is the theory of capillary phenomena at p. 197, about which the less we say the better.

M. Gaudin is favourably known to science as an adept in the management of the blow-pipe. He has melted the most refractory bodies, and compounded the oriental ruby from its elements. He has not only established the chemical formula of silica and modelled its molecule, but he has fused quartz into beads, and drawn it into threads like spun glass.

His experimental researches have displayed great ingenuity and manipulative skill, but have often been brought to an untimely end for want of funds to carry them on. In his theoretical speculations he has been guided by geometry alone, without the powerful if not absolutely necessary aid of dynamics; and in the great work of his life he has met with very little encouragement, and has been sustained only by his conviction of the scientific value of the treasure of which he is in search.

OUR BOOK SHELF

A Manual of Photography. By George Dawson, M.A. Eighth edition. (J. and A. Churchill.)

THE new edition of this excellent manual of photography, which is founded on and incorporates as much of Hardwick's "Photographic Chemistry" as is valuable in the present further advanced stage of the art, retains its position as the best work on the subject for amateurs, as well as professionals. The many new methods and materials which are so frequently being introduced, make it essential that any book professing to keep up to the times must be frequently revised, and Dr. Dawson has in this work presented the subject in its most advanced position. The earlier chapters, after giving a short sketch of the history of photography, enter into a description of the most important experiments, the expansion of which make up the subject itself. This is followed by a review of the various lenses required for the many different purposes to which photography is applied, and their peculiarities are rendered more evident by the introduction of very clear diagrams of them in section. After a full description of the various points connected with the wet-plate

collodion process, considerable space is devoted to the more modern subject of dry-plate photography. The many precautions necessary in the employment of the collodio-bromide negative process, as introduced by Messrs. Sayce and Bolton, and improved by Mr. Carey Lea and Colonel Wortley, are fully entered into; and the very rapid method introduced by the latter gentleman, in which the collodion is saturated with nitrate of silver, is given with some very recent formulæ. The subject of printing in pigments, so important in the present day, which "doubtless would become universal were the processes unfettered by patents," is fully described, with the difficulties attending the "double transfer" of the gelatin film. Following the details of photolithography, photozincography is that of collotype printing, which has become so prominent of late. A vocabulary of chemicals ends this valuable and suggestive work, of which, from want of space, we have had to omit the mention of many points.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Science at Cambridge

THERE are some points in two articles which have lately appeared in your periodical upon which I should like to make a few remarks. First, however, allow me to congratulate the author upon having deprived the opponents of "Science" of a time-honoured monopoly. For a certain quiet insolence of conscious superiority and an inability to see more than one side of a question, his articles equal any diatribes that I have heard or read from the most intolerant supporter of "the old ecclesiasticism and false culture."

Let that pass, however, and let us proceed to examine one or two statements in detail. "Science is all but dead in England, . . . perhaps deadest of all at our Universities." Now on reading the word science, one has always to ask what a writer means, and the probability is that he means what is commonly called natural science; our writer, however, kindly gives us a definition—"that searching after new knowledge which is its own reward."

Most certainly the more eminent among our Professors and resident Fellows (and some of them are known even in Germany) cannot be said to have followed learning for any other reward; or if so they have taken their pigs to a very poor market. He will, perhaps, say that they have fellowships and professorships. Yes, the aggregate value of which will vary from probably six to nine hundred a year, coupled, in some cases, with conditions which seriously diminish their value. Is this so great a prize?

Again, we are represented as encouraging by prize fellowships and "that kind of liberal education which softens the character and prevents it being strong." I hardly know what the writer means; however, the following are the studies which we do endeavour to encourage:—

(1.) Mathematics.—Does the writer seriously mean to apply his remark to this study? If so, I can only say that to those who can appreciate sound and unsound reasoning, there is a marvellous difference between the work of (say) such a geologist as the late Prof. Sedgwick, trained in the school of mathematics, and not a few, whom it would be offensive to name, who have never had that advantage.

(2.) Language.—Perhaps in comparison with looking at mites in a microscope, or analysing some very rare but useless mineral, the attempt to enter into communion with the thought of the master-minds of our race in the past time is a contemptible pursuit; but though with a great regard for both the above pursuits myself, and with no pretension to refined scholarship, I cannot—and hope but few can—agree with this opinion.

(3.) The moral sciences.—If this is meant, I give the writer over to the tender mercies of the philosopher, who, I think, will be able to give an account of him: so also as regards legal studies.

(4.) Natural Sciences.—These are encouraged in precisely the same way as the others (in the case of most colleges). Is this then culture which produces effeminacy?

But perhaps the writer will say that only classics and mathematics are encouraged. To this I reply that the other studies are of recent growth in the University—I admit that they ought to have taken root long ago—that however is not our critic's charge—he is dealing with the present—and I have no hesitation in affirming that in all the important colleges the students of natural science have just as good a chance of honour and rewards as those of other branches of learning. The number of rewards that have been given is small, because the number of really first-class students has hitherto been small. The number of students (and their quality) increases year by year. I have no fear that as a rule they will meet with their deserts.

Or does the writer mean to say that our fault is teaching and examining, that we ought to open laboratories (for notwithstanding his definition, I think his science means only one thing) and simply exercise a general superintendence over students? After an experience of some years I can only say that though I do not worship either lectures or examinations (especially the latter), with a blind "idolatry," I believe without them the majority of young students are very apt to become slipshod and slovenly in their work.

But the trumpet's sound is so uncertain that I know not exactly what the writer does mean. I have read over and over again his *tertium quid* (p. 41), in supporting which he confesses he is with a select few—doubtless the salt of the earth—and I still am doubtful. They be very "brave words"—but "to make the University a place where anyone and everyone may be trained for any and every respectable path of life," is just the aim of every change that has been made since I have known the place. Our students—of subjects not classical—certainly increase yearly, and I have not heard of any marked deportation to the Elysian fields of either Manchester, London, Newcastle, or Germany. Neither have I found that such "master minds of the age" as are within our walls (and I think, subject to the writer's approval there are some) inaccessible to students.

In conclusion I must state in self-defence that I am not usually considered a conservative. I have done all that was in my power to help the cause of University Reform, and especially of Natural Science. But much as I delight in the latter I decline to regard it as the only culture, the only training worthy of respect. I trust to live to see yet greater changes. These however will not be obtained by vague declamations or reckless accusations—such as "long years of misrule have left suckers of jobbery, like bind-weed in an old garden, which come up refreshed with every stirring of the soil." After twelve years of active life in the University—and often failing to obtain what I wanted—I unhesitatingly assert that there is no place where there is so little jobbery, or where the motives that actuate men, even if mistaken, are so generally pure as here. There are jobs everywhere now and then, even in scientific societies or coteries.

There are indeed difficulties in the way of reform, but the writer of the articles, I venture to think, has not hit the nail on the head. May I, before ending this long letter, in a few words indicate one or two—1. The workers in the University should govern it. At present a body called the Senate, consisting chiefly of non-residents, has the final decision of everything. Throw all the power into the hands of the working bees, and we will reform ourselves fast enough. 2. The waste of money in non-resident fellowships. There are very few here who would defend the present system, but we have no power to change it ourselves. 3. The poverty of the Universities. To relieve this we must have power given to colleges to alter their statutes, and so long as the University is governed by the Senate, we in the colleges do not care to put beyond our control funds which might then even be applied to political or theological squabbles. 4. An improvement of the Professorial System—more teachers and rather less routine work, with greater unity of action between the former. Give us powers, and we will soon settle that. We are bound, like the Jews, "by a chain of ordinances," and till that is broken cannot help ourselves. T. G. BONNEY

St. John's College, Cambridge

Arctic Exploration

THE news of Mr. Hall's Arctic Exploration is important from two points of view, and I shall be obliged if you will allow me the space to point out the lessons to be derived from it, and the way in which the new facts strengthen the arguments for Polar exploration.

But first it is most important that the attempt of the *Times* to injure the cause of Arctic discovery, in an article published last Saturday (May 24), should be examined; for if all the arguments of the enemies of knowledge are summed up in that article, they are weak indeed. Such as they are, these arguments are propped up by three incorrect statements which must, in the first place, be knocked away. First it is alleged that "men of science cannot tell us what are the problems they hope to clear up" by Arctic discovery. This assertion is disproved by the documents published by the *Times* itself on December 16, in which the objects of Arctic exploration are clearly and distinctly enumerated. That this enumeration may be, and should be made more exhaustive, you pointed out at the time, and your suggestions have been adopted. But the objects are clear enough, and have been clearly stated. Briefly they are the investigation of the geography, hydrography, geology, meteorology, fauna, flora, and ethnology of an unknown area covering several million square miles of the earth's surface. Secondly, the *Times* alleges that Arctic Explorers "made little of the dangers of the proposed expedition." This is a mistake. Arctic Explorers have done nothing of the kind. They are perfectly aware of the extent and scope of the dangers, and how they can be reduced to a *minimum*, and they have furnished the Government with the results of their experience. Thirdly, it is asserted by the *Times* that geographers "confidently cited the pending close of Mr. Hall's Expedition as a conclusive fact to be argued from." This also is incorrect. Mr. Hall's expedition was simply mentioned in their address, without any comment, and no argument whatever was derived from it; for the very good reason that its history was then unknown. Very strong arguments, however, will now be based upon the facts stated by the boat's crew of the *Polaris*.

These erroneous statements being refuted, the whole argument in the *Times* article, falls to pieces. There remains a highly-coloured version of the story told by the boats' crew of the *Polaris*, garnished with sensational sentences, of which the following are examples:—"*Death, in a hundred ghastly shapes, dogs the shadow of this phantom ship*" . . . "*Are we morally justified in exposing human beings to the slow torture of a solitary death by famine or by cold?*" and the like; the moral being, that because the writer in the *Times* has imagined some fanciful nightmare, therefore no Englishman is again to venture into the Arctic Regions.

Let us turn to the plain facts. The *Polaris* is a vessel wholly unsuited for ice navigation; she was commanded by a landsman, and her crew was undisciplined and not under proper control. Yet she passed safely through Baffin's Bay and far up Smith Sound, where at least two exploring parties made journeys to the north; she wintered, and was drifted out into Baffin's Bay last summer, where part of the crew deserted with all the boats. But she had plenty of provisions, could easily winter in Whale or Wolstenholme Sounds, where there are friendly Esquimaux, could construct a boat if necessary, and a fleet of whalers will be in the "North Water," ready to give assistance, this summer. Obviously the blame of any disasters that may have befallen her cannot be imputed to the Arctic Regions. Under the circumstances, she would have been leaky, her crew would have been mutinous, and she would have lost her boats in any other climate. These events are due to the way in which the expedition was organised, not to the temperature.

An English Arctic Expedition, consisting of two vessels adapted for ice navigation with a picked crew under naval discipline, and commanded by an experienced seaman, will run no such risks. One vessel, as a depôt, could be stationed near the entrance of Smith Sound, while the other pressed to the north; so that, in the improbable event of the advanced ship being lost, her crew could retreat to the consort. The dangers of Arctic exploration are involved in the travelling and boat-work, and in exposure to frost-bites and over-fatigue. They are not such as Englishmen may not freely and prudently encounter in the cause of science and discovery. They are such as our ancestors were eager and anxious to meet and overcome, and as their descendants, in spite of the *Times*, intend to encounter again and again. They apply to individuals, not to the expedition as a body, and have been reduced to a *minimum* by modern science and experience. The climate is the healthiest in the world, the scenery enchanting, the work most interesting and fruitful. The *Times* alleges that former Arctic expeditions have brought back nothing but "a few insignificant facts, and a multitude of barren conjectures." This is the exact reverse of the truth. They have brought back a multitude of important facts in all branches of science, and priceless collections. To them is due the lucrative whale and seal-fisheries, great stores of knowledge, the materials for such papers as that by Dr. Hooker on the *Arctic flora*, and for many others of similar value.

The news brought by the boat's crew of the *Polaris*, if at all accurate, is very important. It proves that even such a vessel as the *Polaris* may advance up Smith Sound, in one season, to 82° 16′ N. It is stated, also, that at, or near this point, the land, both of Greenland and Grinnell Land, was still trending northward. From such a point, an extended party, with depôt parties, organised on McClintock's principles of sledge travelling, could reach the North Pole and return to the ship. Another important fact is that the *Polaris* was beset in 80° 2′ N. and drifted out into Baffin's Bay. This shows that there is not a constant block of ice in the strait, but that the floes drift down with the current, leaving, as a consequence, an occasional navigable lane between the drifting ice and the land floe. These facts are most satisfactory, and increase the prospect of a successful exploration of the unknown region by way of Smith Sound. I think that you have already announced the nomination of an Arctic Committee by the Council of the Royal Society, to confer with the Committee of the Geographical Society; and we may fairly anticipate that when these bodies again bring the subject to the attention of Her Majesty's Government this summer, the case, both as regards the important objects to be attained by Arctic exploration, and the measures to be adopted, will be materially strengthened.

Late of H.M.S. *Assistance* in the Arctic Expedition of 1850 51.

Forbes and Tyndall

PROF. HUXLEY is at a loss "to discover any excuse for the biographer" having published, at pp. 386-7 of the "Life and Letters of the late Principal Forbes," a letter, with an extract from which he heads his own letter in the last number of NATURE. For publishing that letter no excuse need be offered, because a sufficient reason can be given.

The discussions regarding the glacier question, and the decision of the Council of the Royal Society regarding the Copley Medal in the autumn of 1859, are matters well known to all who take interest in such subjects. Some further light has been thrown upon the history of the latter transaction by the recent letter of Prof. Huxley. Neither into the overt facts, nor into their secret springs, was it my duty as a biographer to enter. But it was my duty to record the impression made on Forbes's mind by the treatment he then received. This I did, not by "deliberately picking expressions out of a private letter," as Prof. Huxley phrases it, but by giving, without note or comment, nearly the whole of a letter written by Forbes at the time to his friend Mr. A. Wills.

Instead of objecting to the few lines on this subject which have been allowed to appear, Prof. Huxley may rather appreciate the reserve which has passed over so lightly a transaction in which the late Principal Forbes felt that he was deeply wronged. But it was the desire of the biographers to exclude, as much as possible, all controversial matters, not from any doubt as to the justice of Forbes's claims as a glacier discoverer, but in order, as far as might be, to avoid strife. If they have not succeeded in doing so as completely as they wished, this has not been their fault. When the book was almost through the press, they found themselves, by the appearance of Prof. Tyndall's work on the "Forms of Water," constrained to depart somewhat from their original intention, and to include two statements which Forbes had written on the subject of his glacier discovery, and which are now to be found in Appendix A and Appendix B of his "Life." These contain the gist of the whole question, as far as Forbes was concerned. Neither the one nor the other has ever yet been refuted in any point. If Prof. Huxley desires to justify the action of himself and others who opposed Forbes in 1869—and to deal with the question in the only way in which the world is at all concerned with it—let him try to disprove the facts and refute the statements contained in these two appendices. If he succeeds in this attempt, he will have removed the grounds on which Forbes rested his claims to be held as a glacier discoverer. Till this has been done, to discuss merely incidental personal allusions is to miss the point, and to evade the main issue.

Houston House, Linlithgowshire, May 26

Clerk-Maxwell's Kinetic Theory of Gases

YOUR correspondent, Mr. Guthrie, has pointed out an, at first sight, very obvious and very serious objection to my kinetic theory of a vertical column of gas. According to that theory, a vertical column of gas acted on by gravity would be in thermal equilibrium if it were at a uniform temperature throughout, that is to say, if the mean energy of the molecules were the same at all heights. But if this were the case the molecules in their free paths would be gaining energy if descending, and losing energy if ascending. Hence, Mr. Guthrie argues, at any horizontal section of the column a descending molecule would carry more energy down with it than an ascending molecule would bring up, and since as many molecules descend as ascend through the section, there would on the whole be a transfer of energy, that is, of heat, downwards; and this would be the case unless the energy were so distributed that a molecule in any part of its course finds itself, on an average, among molecules of the same energy as its own. An argument of the same kind, which occurred to me in 1866, nearly upset my belief in calculation, and it was some time before I discovered the weak point in it.

The argument assumes that, of the molecules which have encounters in a given stratum, those projected upwards have the same mean energy as those projected downwards. This, however, is not the case, for since the density is greater below than above, a greater *number* of molecules come from below than from above to strike those in the stratum, and therefore a greater number are projected from the stratum downwards than upwards. Hence since the total momentum of the molecules temporarily occupying the stratum remains zero (because, as a whole, it is at rest), the smaller number of molecules projected upwards must have a greater initial velocity than the larger number projected downwards. This much we may gather from general reasoning. It is not quite so easy, without calculation, to show that this difference betwen the molecules projected upwards and downwards from the same stratum exactly counteracts the tendency to a downward transmission of energy pointed out by Mr. Guthrie. The difficulty lies chiefly in forming exact expressions for the state of the molecules which instantaneously occupy a given stratum in terms of their state when projected from the various strata in which they had their last encounters. In my paper in the *Philosophical Transactions*, for 1867, on the "Dynamical Theory of Gases," I have entirely avoided these difficulties by expressing everything in terms of what passes through the boundary of an element, and what exists or takes place inside it. By this method, which I have lately carefully verified and considerably simplified, Mr. Guthrie's argument is passed by without ever becoming visible. It is well, however, that he has directed attention to it, and challenged the defenders of the kinetic theory to clear up their ideas of the result of those encounters which take place in a given stratum. J. CLERK MAXWELL

Additional Remarks on Abiogenesis

SINCE my communication in NATURE, March 20, a further investigation of the subject has shown me that the experiments there recorded do not yet fully prove the reality of abiogenesis. My argumentation based on those experiments is liable to the following objection:—

The principal experiment (water, potassium-nitrate, magnesium-sulphate, calcium-phosphate, glucose, and peptone) is conducted in a *neutral* solution. In the control-experiments neutral ammonium-tartrate is used as nutritious substance for the supposed germs. But this salt disassociates by boiling, loses ammonia, and the reaction becomes *acid*. When, therefore, Bacteria appear in the principal experiment and not in the control-experiments, this result can be explained by admitting that the germs resist a temperature of 100° in a neutral liquid, but are killed by the same temperature in an acid solution. This explanation agrees very satisfactorily with the fact proved by Pasteur, that an acid reaction is much more deleterious to living germs than a neutral reaction at the same temperature.

This objection is very rational, but it does not throw over my conclusion respecting the reality of abiogenesis, for the following reasons:—

It is now obvious that in the control-experiments ammonium-tartrate cannot be used, a nitrogenous body must be sought, not too complex, that remains neutral by 100°. For this end I have found urea to answer well. Pure urea is perfectly fit to furnish nitrogen to the Bacteria, but not to furnish them their carbon. Bacteria sown in a solution of urea and mineral salts do not develop themselves, but when sugar is added their growth goes forth rapidly. The following solution—100 c.c. water, 0·2 grms. potassium-nitrate, 0·2 grms. magnesium-sulphate, 0·04 grms. calcium-phosphate, 1 grm. glucose, 0·5 grm. urea, is eminently fit for the development of Bacteria. Also a solution that contains, instead of the sugar and the urea, 0·5 grm. peptone.

These solutions were now used in the control-experiments. For instance:

a. Principal experiment. 100 c.c. salt-solution,* 2 grms. glucose, 0·3 grms. peptone boiled and treated in the ordinary manner (See NATURE, vol. vii. p. 380). On the third day the liquid contains countless swarms of Bacteria.

b. Control experiment. 100 c.c. salt solution, 1 grm. glucose, 0·5 grm. urea, boiled exact. No Bacteria appear; on the eighth day the liquid is perfectly clear.

c. Control experiment. 100 c.c. salt solution, 0·5 grm. peptone, boiled, &c. On the eighth day complete absence of Bacteria.

In each of these experiments the reaction is neutral. They are therefore fully comparable. The experiments *b* and *c* prove, moreover, that the closing tiles exclude completely the atmospheric germs, a fact that was also proved by direct experiments, wherein the solutions *b* and *c* were used and dust strewn on the closing tile in the manner formerly described.

But is it not possible to generate Bacteria in a liquid which has been boiled when acid?

To elucidate this point, the above-named solution *a* was rendered acid (2 – 4 c.c. of a 1 per cent. solution to 100 c.c.) and treated as usual. No Bacteria appeared, whether the liquid was, after boiling, neutralised with soda or not.

But this negative result is easily conceivable; for the acid alters essentially the calcium-phosphate, changes $CaHPO_4$ into $Ca_2H_4P_2O_8$. And that this alteration is not without influence, is rendered probable by the fact, which I have recorded in the *Maandblad voor Natuurwetenshcappen*, No. 7 (April 23, 1873), namely, when in the principal experiment instead of $CaHPO_4$ is used a mixture of $Ca_3P_2O_8$, and $Ca_2H_4P_2O_8$ the result (the genesis of Bacteria) is much less constant. The neutral calcium-phosphate by boiling with water breaks up in the basic and the acid salt, but this division must take place in the presence of sugar and peptone.

On the other hand, the acid modifies the peptone. This is easily demonstrated by comparing, in the polariscope, the rotating power of a neutral peptone-solution with the power of the same solution. After boiling with acid a notable difference is observed.

The acid can, nevertheless, be employed with the following modification:—In 100 c.c. water are dissolved 0·2 grm. potassium-nitrate, 0·2 grm. magnesium-sulphate, and 2 grms. glucose; 2 c.c. of a 1 per cent. solution of tartaric acid are added, so that the liquid has a strong acid reaction. It is then boiled for ten minutes. Then with a red hot platinum spatule a little soda is taken from a hot crucible and thrown in the flask. The quantity of soda required is approximately ascertained by a preliminary trial. Care should be taken not to render the liquid alkaline. Then 0·05 grm. calcium phosphate and 0·3 grm. peptone are added together, and the boiling continued for ten minutes. The flask is closed as usual, and deposited in the hatching-bath. Three days after, it swarms with Bacteria.

When, instead of calcium-phosphate and peptone, are added 0·05 grm. calcium-phosphate and 0·5 grm. urea, nothing appears; and the result is equally negative when the following solution is taken:—100 c.c. water, 0·2 grm. potassium-nitrate, 0·2 grm. magnesium-sulphate, 0·05 grm. calcium-phosphate, 1 grm. potassium-natrium-tartrate, 0·3 grm. peptone. In this latter case no acid is used. The addition of the tartrate is made to have a sufficient quantity of carbon in the liquid. These control experiments prove that none of the employed materials, neither the glucose, nor the calcium-phosphate, nor the peptone did introduce germs.

By these experiments the above-stated objection is, in my opinion, satisfactorily refuted.

In concluding these remarks, I must mention an important fact. For the above-described experiments, I employed mostly the ordinary glucose, an amorphous, yellowish white mass, not chemically pure. By crystallisation from strong alcohol, I purified this sugar. In three different preparations I obtained thus three samples of perfectly white more or less pure glucose. One

* Composed of 1 grm. potassium-nitrate, 1 grm magnesium sulphate, 0·2 grm. neutral calcium-phosphate in 500 c.c. water.

of these samples yielded, with peptone, Bacteria; not so the other two. All three were prepared with the utmost caution respecting atmospheric dust, &c. That, moreover, the positive result could not be caused by an accidental admixture of germs was amply proved by the often repeated control-experiments. It appears, therefore, that, besides the glucose and the peptone, a third substance is needed for generating Bacteria, a body present in the ordinary glucose (starch-sugar), but removed by purification. The nature of this body I have not yet been able to ascertain. But however important, this matter has no direct bearing upon the question of abiogenesis. For that this third unknown body cannot be (as some will probably presume) a germ, my control-experiments and also the above-described experiment, wherein the sugar was boiled with acid, do sufficiently prove. D. Huizinga

Groningen, May 23

Flight of Birds

Some time since I had occasion to ascend a mountain in the neighbourhood. The wind was blowing over the ridge-like crest of the mountain with a velocity of, I should say, ten or twelve miles an hour, sweeping with increased rapidity through certain transverse gorges cutting the ridge at right angles. In one of these I observed a hawk hovering in search of prey. In the midst of this rapid air current the bird remained apparently *fixed* in space, without fluttering a wing, for at least two minutes. After a time it gently changed its position a few feet with a slight motion of its wings, and then came to rest again as before, remaining apparently as motionless as the rocks around it. From my nearness to it a change of position of an inch would have been clearly visible, and yet except when it seemed to desire to change its point of observation no motion of any kind could be detected. How is this to be accounted for? Does a bird possess the power of giving an extremely rapid tremulous motion to its wings invisible even at a small distance, similar in its nature to the wing vibration of certain insects, which, as any one may have noticed, have a similar power of apparently fixing themselves in space over a flower, for example, notwithstanding a condsiderable amount of motion in the air in which they are suspended?

If any of your correspondents would kindly take the trouble to throw some light on these points they would greatly oblige one who is unfortunately placed out of reach of the ordinary means of reference. J. Guthrie

Graaff Reinet, Cape Colony, April 2

THERMO-ELECTRICITY

THE subject I have chosen is one intimately connected with the names of at least two well-known members of this University—the late Prof. Cumming and Sir William Thomson. It possesses at present peculiar interest for the physicist; for, though a great many general facts and laws connected with it are already experimentally, or otherwise, secured to science—the pioneers have done little more than map the rough outlines of some of the more prominent features of a comparatively new and almost unexplored region. Some of its experimental problems are extremely simple, others seem at present to present all but insuperable difficulties. And it does not appear that any further application of mathematical analysis can be safely, or at least usefully, made until some doubtful points are cleared up experimentally.

The grand idea of the conservation, or indestructibility, of energy :—pointed out by Newton in a short Scholium a couple of centuries ago, so far at least as the progress of experimental science in his time enabled him to extend his statements :—conclusively established for heat at the very end of last century by Rumford and Davy; and extended to all other forms of energy by the splendid researches of Joule :—forms the groundwork of modern physics.

Just as, in the eye of the chemist, every chemical change is merely a re-arrangement of indestructible and unalterable matter; so to the physicist, every physical change is merely a transformation of indestructible energy; and thus the whole aim of natural philosophy, so far at least as we yet know, may be described as the study of the possible transformations of energy, with their conditions and limitations; and of the present forms and distribution of energy in the universe, with their past and future.

It is found by experiment that some forms of energy are more easily or more completely transformable than others, and thus we speak of higher and lower forms, and are introduced to the enormously important consideration of the degradation, or, as it is more commonly called, the dissipation, of energy. The application of mathematical reasoning to the conservation of energy presented no special difficulties which had not, to some extent at least, been overcome in Newton's time: but it was altogether otherwise with the transformations of energy. And it is possible that, had it not been for the wonderfully original processes devised by Carnot in 1824, we might not now have secured more than a small fraction of the immense advances which science has taken during the last thirty years.

For a transformation of heat we must have bodies of different temperatures. Just as water has no "head" unless raised above the sea-level, so heat cannot do work except with the accompaniment of a transference from a hotter to a colder body. Carnot showed that to reason on this subject we must have *cycles* of operations, at the end of which the working substance is restored exactly to its initial state. And he also showed that the test of a *perfect* engine (*i.e.* the best which is, even theoretically, attainable) is simply that it must be *reversible*. By this term we do not mean mere backing, as in the popular use of the word, but something much higher—viz. that, whereas, when working directly, the engine does work during the letting down of heat from a hot to a cold body; when reversed, it shall spend the same amount of work while pumping up the same quantity of heat from the cold body to the hot one. As a reversible engine may be constructed (theoretically at least) with any working substance whatever, and as all reversible engines working under similar circumstances must be equivalent to one another (since each is as good as an engine can be) it is clear that the amount of work derivable from a given amount of heat under given circumstances (*i.e.* the amount of transformation possible) can depend only upon the temperatures of the hot and cold bodies employed. In this sense we speak of Carnot's Function of Temperature, which is as imperishably connected with his name as is the Dynamical Equivalent of Heat with that of Joule.

Building upon this work of Carnot, Sir W. Thomson gave the first *absolute* definition of temperature—that is a definition independent of the properties of any particular substance. Perhaps there is no term in the whole range of science whose meaning is correctly known to so few even of scientific men, as this common word temperature. It would not, I think, be an exaggeration to say that there are not six books yet published in which it is given with even an approach to accuracy. The form in which the definition ultimately came from the hands of Joule and Thomson enables us to state as follows the laws of transformation of energy from the heat form.

1. A given quantity of heat has a definite transformation equivalent.

2. But only a fraction of this heat can be transformed by means even of a perfect engine: and this fraction is DEFINED as the ratio of the range through which the heat actually falls to that through which it might fall—were it possible to obtain and employ bodies absolutely deprived of heat.

This definition has two great advantages. 1st, The utmost amount of work to be got from heat under any circumstances of temperature is determined by precisely the same law as that assigning the work to be had from

* Abstract of the Rede Lecture delivered in the Senate House, Cambridge, May 23, 1873.

water under similar circumstances of level. In this case the sea-level corresponds to what is called the Absolute Zero of temperature. [It is well to observe here that it is the potential energy of the water, not the quantity of water itself, which corresponds in this analogy to the quantity of heat. In this simple remark we have all that is necessary to correct Carnot's reasoning in so far as it was rendered erroneous by his assumption of the materiality (and consequent indestructibility) of heat.] 2nd, Temperatures thus defined correspond, as Thomson and Joule have shown by elaborate experiments, very closely indeed with those given by the air-thermometer—the absolute zero being about 274° of the Centigrade scale below the freezing point of water. I have made this digression as I shall have frequently to use the word temperature, and I shall always employ it in the sense just explained.

The subject of Thermo-electricity of course includes all electric effects depending on heat, but in this lecture I shall confine myself to the production by heat of currents in a circuit of two metals.

The transformation of heat into the energy of current electricity was first observed by Seebeck in 1820 or 1821. His paper on the subject (Berlin Ac., 1822-3, or Pogg. vi.) is particularly interesting, as he gives the whole history of his attempts to obtain a voltaic current from a circuit of two metals without a liquid, and the steps by which he was led to see that heat was the active agent in producing the currents he eventually obtained. In this paper Seebeck gave the relative order of a great number of metals and alloys in the so-called thermo-electric series, and showed that several *changes of order* occurred among them as the temperature was gradually raised.

In a note attached to this paper, Seebeck recognises that in this further discovery he was anticipated by Cumming (who seems, in fact, to have made an independent discovery of Thermo-electricity). Cumming showed that when wires of copper, gold, &c., were gradually heated with iron, the deflection rose to a maximum, then fell off, and was *reversed* at a red heat.

[Seebeck's original experiment and Cumming's extension of it were exhibited.]

You see that, keeping one of the copper-iron junctions at the temperature of the room and gradually heating the other, I produce a current which increases in intensity more and more slowly till it reaches a maximum, then falls off faster and faster till at last it vanishes and thereafter sets in the *opposite* direction. We are still far below the melting point of copper, yet further heating up to that point produces but little additional effect. The reason of this will be apparent from some facts to be described towards the end of the lecture. At the moment of maximum current the two metals are thermo-electrically *Neutral* to one another.—The temperature in the present case is about 280° C.

Seebeck pointed out that bismuth and antimony (to the choice of which he had been led by a very curious set of arguments) were very far removed from one another in the series, and therefore gave large effects for small differences of temperature. This is still taken advantage of in the Thermo-electric Pile, which, when combined with a sufficiently delicate galvanometer, is even now by far the most delicate thermometer we possess. It has recently enabled astronomers to detect and measure the heat which reaches us from the moon, and even from the brighter fixed stars. In the skilful hands of Forbes and Melloni this instrument was the effective agent in demonstrating the identity of thermal and luminous radiations—a step which, as regards the simplification of science, is as important as the discovery of magneto-electricity; and which was completed by Forbes when he succeeded in polarising radiant heat.

But when we come to look at this question from the point of view of transformation of energy, we have to ask *where* is the absorption, and *where* the letting-down of heat, to which the development of the current considered as a rise of energy is due. Very remarkably, an experiment of Peltier supplies us with at least part of the answer. Peltier showed that, given a metallic junction which when heated would give a current in a certain direction, then provided a battery were interposed in that circuit (initially at a uniform temperature) so as to send a current in that direction, the passage of the current *cooled* the junction, while a reversal of the current heated it. This, considering the circumstances under which it was made, and the deductions since drawn from it, is one of the most extraordinary experimental discoveries ever made. Water was frozen, in an experiment by Lenz, by means of the Peltier effect.

Here then is a reversible heat effect, and to it we may reasonably assume that the laws of thermodynamics may be applied; although from the very nature of the experiment the reversible effect must always be accompanied by non-reversible ones, such as dissipation by heat-conduction, and by heat generated in consequence of the resistance of the circuit. The latter of these is in general small in thermo-electric researches, but the former may have large values.

It is known from the beautiful experiments of Magnus that no thermo-electric current can be produced by unequal heating in a homogeneous circuit, whatever be the variations of section—a negative result of the highest importance. Sir W. Thomson, to whom we are indebted for the first and the most complete application of thermodynamics to our subject, showed that the existence of a neutral point necessitates the existence of some other reversible effect besides that of Peltier. And even if the circuit varied in section, the result of Magnus, just referred to, showed that this could only be of the nature of a convection of heat by the current between portions of the same metal at different temperatures. Thomson's reasoning is of the very simplest character, as follows:—Suppose the temperature of the hotter junction to be that of the neutral point, there is no absorption or evolution of heat there; yet there is evolution of heat at the colder junction, and (by resistance) throughout the whole circuit. The energy which supplies this must be that of the heat in one or both of the separate metals; but reasoning of this kind, though it proves that there must be such an effect, leaves to be decided by direct experiment what is the nature and amount of this effect in each of the metals separately. By an elaborate series of ingenious experiments Thomson directly proved the existence of a current convection of heat, and (curiously enough) of opposite signs in the first two metals (iron and copper) which he examined. In his own words, "Vitreous Electricity carries heat with it in an unequally heated copper conductor, and Resinous Electricity carries heat with it in an unequally heated iron conductor." This statement is not very easy to follow. It may perhaps be more intelligible in the form:—In copper a current of positive electricity tends to equalise the temperature of the point it is passing at any instant with that of the point of the conductor which it has just left, *i.e.*, when it passes from cold to hot it tends to cool the whole conductor; when from hot to cold, to heat it, thus behaving like a real liquid in an irregularly heated tube. The effects in iron are the opposite; and Thomson therefore speaks of the specific heat of electricity as being thus positive in copper and negative in iron. He gives a very remarkable analogy from the motion of water in an endless tube (with horizontal and vertical branches), produced by differences of density, due to differences of temperature. Here the maximum density of water plays a prominent part. Neumann has recently attempted, by means of the laws of motion of fluids, and the unequal expansibility of different metals, to give a physical explanation of thermo-electric currents. But, not to speak of the fact that positive electricity is by him considered

as a real fluid, there are the fatal objections that his method makes no provision for the explanation of the Peltier, or of the Thomson, effect; and therefore cannot be looked upon as having any useful relation to the subject. Similar remarks apply to the attempt of Avenarius to account for thermo-electric currents by the variation with temperature of the electrostatic difference of potentials at the points of contact of different metals.

By employing the thermo-electric pile instead of the thermometers used by Thomson, Le Roux has lately measured the amount of the specific heat of electricity in various metals, and has shown that it is very small, or altogether absent, in lead. Strangely enough, though he has verified Thomson's results, he does not wholly accept the theoretical reasoning which led to their prediction and discovery.

One of Thomson's happiest suggestions connected with this subject is the construction of what he calls a thermo-electric diagram. In its earliest form this consisted merely of parallel columns, each containing the names of a number of metals arranged in their proper thermo-electric order for some particular temperature. Lines drawn connecting the positions of the name of any one metal in these successive columns indicate how it changes its place among the other metals as the temperature is raised. Thomson points out clearly what should be aimed at in perfecting the diagram, but he left it merely as a preliminary sketch. The importance of the idea, however, is very great; for, as we shall see, the diagram when carefully constructed gives us not merely the relative positions of the metals at various temperatures, with the temperatures of their neutral points, but also gives graphic representations of the specific heat of electricity in each metal in terms of the temperature, the amount of the Peltier effect, and the electromotive force (and its direction) for a circuit of any two metals with given temperatures of the junctions. In short, the study of the whole subject may be reduced to the careful drawing by experiment of the thermo-electric diagram, and the verification of Thomson's thermo-dynamic theory will then be effected by a direct determination either of Peltier effects or of specific heat of electricity at various temperatures, and their comparison with the corresponding indications of the diagram.

The diagram is constructed so that abscissæ represent absolute temperatures, and the difference of the ordinates of the lines for any two metals at a given temperature is the electromotive force of a circuit of these metals, one of the junctions being half a degree above, the other half a degree below, the given temperature.

It will be seen by what follows that nothing but direct measurement of the value of the specific heat of electricity at various temperatures can give us the actual form of the line representing any particular metal; but if the line for any one metal be assumed, those of all others follow from it by the process of differences of ordinates just described. So that it is well to begin by assuming the axis of abscissæ as the line for a particular metal (say lead, in consequence of Le Roux's result); and if, at any future time, this should be found to require change, a complex shearing motion of the diagram parallel to the axis of ordinates will put all the lines simultaneously into their proper form.

Thomson's theoretical investigation may be put in a very simple form as follows:—Let us suppose an arrangement of two metallic wires, one end of each of which is heated, their cold ends being united, and in which the circuit can be closed by a sliding piece or ring, always so placed as to join points of the two metals which are at the same temperature t. Let E be the electromotive force in the circuit, Π the Peltier effect, and σ_1, σ_2 the specific heats of electricity in the two metals. Then, if the sliding piece be moved from points at temperature t to others at $t+\delta t$, the first law of thermodynamics gives by inspection the equation

$$\delta E = J\,(\delta\Pi + \overline{\sigma_1 - \sigma_2}\,\delta t),$$

and the second law gives

$$0 = \delta\left(\frac{\Pi}{t}\right) + \frac{\sigma_1 - \sigma_2}{t}\,\delta t.$$

These equations show at once that, if there were no electric convection of heat, or if it were of equal amount in the two metals, the Peltier effect would always be proportional to the absolute temperature; and the electromotive force would be proportional to the difference of temperatures of the junctions; so that there could not be a neutral point in any case. In fact, the lines in the diagram for all metals would be parallel: and, on the former of the two hypotheses, parallel to the axis of abscissæ.

Eliminating $\sigma_1 - \sigma_2$ between the equations, we have

$$\delta E = J\,\frac{\Pi}{t}\,\delta t.$$

Now, by the construction of the diagram, $\frac{dE}{dt}$ is the difference of the ordinates of the lines for the two metals at temperature t. Hence, *whatever be the form of the lines for two metals*, the Peltier effect at a junction at temperature t is always proportional to the area of the rectangle whose base is the difference of the ordinates, and whose opposite side is part of the axis of ordinates corresponding to absolute zero of temperature. This area becomes less and less as we approach the neutral point, and changes sign (i.e., *is turned over*) after we pass it; the current being supposed to go from the same one of the two metals to the other in each case.

The electromotive force itself, being the integral of $\frac{dE}{dt}$ between the limits of temperature, is proportional to the area intercepted between the lines of the two metals, and ordinates drawn to correspond to the temperatures of the junctions respectively.

Again, the second of the preceding equations shows us that the difference of specific heats in the two metals is proportional to the absolute temperature and to the difference of the tangents of the inclinations of the lines for the metals to the axis of abscissæ. If we assume this axis to be the line of a metal in which the electric convection of heat is wholly absent, the measure of this convection in any other metal is simply the product of the absolute temperature into the tangent of inclination of its line to the axis. Thus, if the thermo-electric line for a metal be straight, electric convection is in it always proportional to the absolute temperature; and it is positive or negative according as the line goes off to infinity in the first or in the fourth quadrant. If the lines for any two metals be straight, and if one junction be kept at a constant temperature, the electromotive force will be a parabolic function of the temperature of the other junction—the vertex of the parabola being at the temperature of the neutral point of the two metals, and its axis being parallel to the axis of ordinates.

For the benefit of such of my audience as are not familiar with mathematical terms, I may give an illustration which is numerically exact. Let time stand for temperature, years corresponding say to degrees. Let the ordinate of one of the metals represent a man's income, that of the other his expenditure. The difference of these ordinates represents the rate of increase of his capital or accumulated savings, which here stands for electromotive force. As long as income exceeds expenditure, the capital increases; when income and expenditure are equal (*i.e.*) at a "neutral point," capital remains stationary, indicating, in this case, a maximum value; for in succeding years expenditure exceeds income, and capital is drawn upon.

(*To be continued.*)

ON THE SPECTROSCOPE AND ITS APPLICATIONS

IX.

NOW let me state to you how the discovery mentioned on p. 12 was finally established by Kirchhoff. In my notice of the spectroscope in the earlier articles, I had so much to say that there were several details it was absolutely essential I should curtail. One of these details was the scale by which the positions of the different bright or dark lines which are

Fig. 50.—A sun-spot (Secchi), showing the "straws" in the penumbra, and the irregular masses on the general surface.

seen in the different spectra are registered, so that we may say that such a line occupies such and such a position, and such another line occupies such another position, with regard to something else. When Kirchhoff and Bunsen, two German chemists, were engaged in mapping the spectra of the elements—a research which at its commencement had nothing whatever to do with the sun—they came across this difficulty of a scale. How could they get a good scale? I have already referred to some very obvious arrangements that might determine the actual position; for instance, the observing telescope may be made to move along a graduated arc, so that by moving the telescope for the different rays and fixing it when in a proper position to see a particular ray, you might read off the index placed on the arc to a great nicety by means of a graduated *vernier* working on the

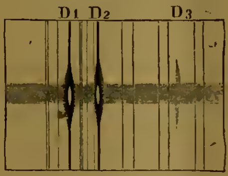

Fig. 51.—Spectrum of sun-spot. (Young.)

curve of the arc; or you may, by a modification of the instrument, use a reduced photographic picture of a scale, so that the thing to be measured and the actual scale would appear in the field of view at the same time. Kirchhoff and Bunsen tried these methods, but they did not like them. Then it suddenly struck them that, as they made their experiments in the day-time, they might use as a scale the black lines in the solar spectrum, which had not been known to change since the time of Wollaston, who discovered them. When working in the day-time, they had thus the solar spectrum visible in one half of the field of view of the telescope, which was easily managed by placing a reflecting prism over one half of the slit, as is shown in the enlarged slit in Fig. 46, so as to light one half of the slit by the sun, and the other half by whatever substance was under examination. With this arrangement they set to work with infinite care, and made a map of the solar spectrum. Such was their pro-

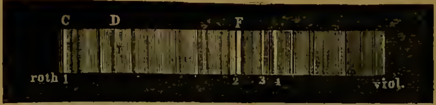

Fig. 52.—Spectrum of τ Coronæ. (Huggins.)

posal: first to map the unchangeable solar spectrum, and then, having this unchangeable scale, about which there could be no mistake, always visible, they would be able to refer to the dark lines in it all the unknown phenomena they were about to investigate in the bright lines of different vapours and gases. Having got this idea of the scale well into their minds, they were exceedingly anxious to test this question, which, as I have told you, was raised by Fraunhofer and many other men before them, of the asserted coincidence of the bright sodium line with the dark solar sodium lines; with a very delicate instrument, Prof. Kirchhoff made the following remarkable experiment:—"In order," says Kirchhoff, for these are his own words, "to test in the most direct manner possible the frequently asserted fact of the coincidence of the sodium lines with the lines D"—(that is to say, of the bright double lines of sodium in the yellow part of the spectrum, with the double line D of the solar spectrum)—"I obtained a tolerably bright solar spectrum, and brought a flame coloured by sodium vapour in front of the slit. I then saw the dark lines D change into bright ones." That is to say, in the spectrum of the sodium which was burning in the flame were lines so exactly coincident with the two dark lines in the solar spectrum, that the bright lines of the sodium spectrum put these dark lines out altogether, so that they seemed to vanish, as it were, from the solar spectrum. He goes on:—"In order to find out the extent to which the intensity of the solar spectrum could be reduced without impairing the distinctness of the sodium lines, I allowed the full sunlight to shine

Fig. 53.—Alteration of wave-length of the hydrogen in the atmosphere of Sirius. 1, Hydrogen at atmospheric pressure; 2, Solar Spectrum Line F; 3, Spectrum of Sirius; 4, Hydrogen in vacuum tube.

through the sodium flame." Here he varies the experiment. In the first instance he used a very feeble beam of sunlight, but he now allows the whole glare of the sun to enter the slit. What was the result? "To my astonishment, I saw that the dark lines D appeared with an extraordinary degree of clearness." That is to say, the lines which came from the sodium in the first instance, were sufficiently bright to entirely eradicate the dark lines from the solar spectrum, but the two lines D were now

so utterly powerless compared with the light of the sun, that they actually appeared as black lines, and coincident with the two lines D in the solar spectrum.

We have seen that the bright line due to the radiation from sodium vapour can be very easily obtained by placing some sodium in a colourless gas flame, but if we now pass the continuous light coming from the carbon points of an electric light, or from the oxyhydrogen lime-light, through this same sodium flame, the result will be that we obtain a black absorption line on a continuous spectrum, in precisely the same position as the yellow line was originally. This is Kirchhoft's crucial experiment, which at once determined not only that the dark line in the sun was absolutely coincident with the bright line of sodium vapour, but that, under certain conditions, bright, incandescent sodium vapour could actually be made to absorb the light coming through it, and reverse its own spectrum. Kirchhoff goes on:—"I then exchanged the sunlight for the Drummond or oxyhydrogen lime-light, which, like that of all incandescent solid and liquid bodies, gives a spectrum containing no dark lines." When this light was allowed to fall through a suitable flame, coloured by common salt (or chloride of sodium), dark lines were seen in the spectrum in the position of the sodium lines." You may imagine that this conclusive experiment—perhaps the most wonderful experiment that has been made during the century—gave Kirchhoff food for thought, and at once his genius travelled to a possible explanation of this strange fact he had observed; a fact, as you know, entirely in accordance with the previsions of Prof. Stokes, Dr. Balfour Stewart, and Foucalt. Kirchhoff said to himself, "I have now got the bright lines in the spectrum of the vapour of sodium coincident with the two dark lines in the solar spectrum. What does it mean?" And again the philosopher was not at fault. He said to himself—it is almost possible to see the train of his reasoning in his memoirs—"Sodium has a most simple spectrum; suppose I take the most complicated spectrum I can find." He took for this purpose the spectrum of iron, which I think you will acknowledge to be one of sufficient complication, for the spectrum is traversed by lines throughout its whole length, and I may tell you at once that no less than 460 lines have been already mapped, and their positions are now thoroughly well known to us—as well known as the position of any star in the heavens. Kirchhoff tried the iron spectrum, and he found, absolutely corresponding in position in the spectrum and in width and darkness to the bright iron lines which he saw, black lines in the solar spectrum. He waited no longer; he instantly convinced himself, and soon convinced the world, that he had discovered this very remarkable fact, that gases and vapours have the power of absorbing those very rays which they themselves give out when in a state of incandescence. So that, if you take sodium, and get its bright lines, and mark their positions on the screen, and then observe a continuous spectrum, and interpose sodium vapour in the path of the beam, you will find black lines absolutely corresponding with the bright ones; that is to say, that the sodium vapour has the faculty of entirely eating up, absorbing, or stopping that light which would otherwise go on to the screen. In the case of iron, it is worthy of notice that when Kirchhoff made his discovery, he was only able to obtain a spectrum of iron consisting of something like 90 lines, but since then the spectrum of iron has been mapped to the extent of 460 lines, and sure enough there are solar lines corresponding to nearly all the 460 bright lines which we are able to get in our laboratories. Not only was the bright line of sodium *reversed* or changed into a dark one, but it was soon found that the lines of other metals, such as lithium, potassium, strontium, calcium, and barium, could be reversed in a similar manner. This grand discovery of Kirchhoff's met with immediate acceptance, and with it you see at once the explanation of the wonderful black lines discovered by Wollaston, about which I said something in my first lecture. The riddle of the sun was read to a certain extent, and Kirchhoff read it in this way. He said:—"There is a solid or a liquid something in the sun, giving a continuous spectrum, and around this there are vapours of sodium, of iron, of calcium, of chromium, of barium, of magnesium, of nickel, of copper, of cobalt, and aluminium; all those are existing in an atmosphere, and are stopping out the sun's light. If the sun were not there, and if these things were observed in an incandescent state, we should get exactly these bright lines from them." Later researches by many distinguished physicists have shown that the following terrestrial elements are present in the vaporous condition round the sun:—

1. Sodium.	6. Chromium.	11. Cobalt.
2. Calcium.	7. Nickel.	12. Hydrogen.
3. Barium.	8. Copper.	13. Manganese.
4. Magnesium.	9. Zinc.	14. Aluminium.
5. Iron.	10. Cadmium.	15. Titanium.

Kirchhoff further imagined that he had reason to believe that the visible sun, the sun which we see—and we may take the sun as an example of every star in the heavens—was liquid.

In the sun we have, first, a bright, shining orb, dimmed to a certain degree at the edge; and here and there, over the sun, we see what are called spots. Kirchhoff wished, not only to connect his discoveries with the solar atmosphere, but was anxious to connect them with this dimming near the limb and the spots. He said that the solar atmosphere, to which all the absorption lines were due, extended far outside the sun, and formed the corona; and that this dimming of the limb was really due to the greater absorption of this atmosphere, owing, of course, to the light of the sun travelling through a much greater length at the limb than at the centre of the disc. Furthermore, he said that the sun-spots, which astronomers, from the time of Wilson, had asserted to be cavities, were nothing but clouds floating in this atmosphere of vapour. Such was the very bold hypothesis put forward by Kirchhoff—an hypothesis which you see at once explains these strange observations from Wollaston upwards, including Fraunhofer's observation of the spectrum of the sun and stars, and the brilliant ideas of Prof. Stokes, Dr. Balfour Stewart, and others in other lands. A little simple experiment, made by means of a little sodium vapour and a beam of sunlight, with the powerful aid of a little prism, gave us this tremendous knowledge about distant worlds so immeasurably remote that it seemed absurd for men to try and grapple with any of the difficulties that are presented to us. Such, then, is Kirchhoff's theory of the sun, which I hope I have been able to make clear to you. There is a something—Kirchhoff said it was a liquid—which gives us a continuous spectrum, and between our eye and that incandescent liquid surface there is an enormous atmosphere, built up of vapours of sodium, iron, and so on; and the reason that we get these dark lines is, that the molecules of the substances named absorb certain rays, because when they are in an incandescent state they produce them. This brilliant idea of Kirchhoff's was soon carried, as you know, to the stars by Mr. Huggins in our own country. In Fig. 34 will be seen the spectra of two stars, Aldebaran and α Orionis (Betelgeux), which are so distant that it is absolutely impossible to measure their distance from us. We know a great deal about our own sun, but these suns are so lost in the depths of space that it is quite impossible that we can get anything like a correct knowledge of their size, or know much of their belongings. By means of the prism, however, we learn in a moment a great deal. In the first star we get three lines, due to the absorption of magnesium vapour, as we get them in the sun. We know, therefore, that magnesium vapour is present in the atmosphere

around that sun (Aldebaran) in exactly the same way as round our own. We also get some of the iron lines, the lines of sodium, and the lines of hydrogen, calcium, and a few other elements—nine in all. At the base of the diagram you see indications of the elements, with the bright lines of which Mr. Huggins has compared the black lines which you see in the spectrum of these heavenly bodies. By means of the star spectroscope and of the induction coil, Mr. Huggins tested these lines, as Kirchhoff did in the case of the sun, by actually getting the vapour of magnesium visible at the same time in the spectroscope: and thus you see in a moment that there is no difficulty at all in determining their coincidence, you have the two things brought so closely side by side. If I had time I might remark on the presence of some elements here and the absence of others; but there is one remarkable fact about this lower star (α Orionis) which I must mention. As far as its spectrum goes, it appears that the gas hydrogen, which is a very important element in our sun's atmosphere, as we gather from the great distinctness of the hydrogen lines in the solar spectrum—and not only in our sun, but in a great many others—is absolutely absent, whilst magnesium, sodium, calcium, &c., are present.

So far, then, you see that this little prism has enabled us to read a great many secrets of the sun and of the more distant stars; and we must acknowledge that Stokes' and Kirchhoff's hypothesis is a very magnificent one, and we can but wish that there were more men like them, who, undismayed by the failure of those who, for nearly a century before their time, had been endeavouring to unravel these secrets, were still prepared to go on, and endeavour to find them out by means of a prism and a simple sodium flame.

Now, astronomers—who, as I told you, from the time of Wilson had imagined that the sunspots were cavities—very soon began to quarrel with this hypothesis of Kirchhoff's, who said that the sunspots, instead of being cavities, were really clouds floating in the atmosphere. They remarked, and I think with truth, that to make such an assertion was altogether opposed to the evidence of the telescope. And I think I may say that the astronomers have now carried the day, for another line of independent research altogether—I mean the researches into the constitution of the sun by means of the spectroscope—has come to the aid of the astronomers, and it looks very much as if we must still hold to the opinion that Wilson in his observations, now more than a century old, was perfectly right, and that Kirchhoff's analysis, as far as it deals with the sun-spots, is susceptible of improvement. In the remarks I made in my former lecture on radiation in connection with the red prominences visible during eclipses, I drew your attention particularly to the hydrogen lines, and told you that the red flames are, for the most part, composed of hydrogen. There the prism comes to our aid in a very remarkable way indeed. It is clear to you, I think, after what I have said about absorption, that the darkening of the sun's surface, which we call a spot, is really a thing about which the prism can tell us a great deal. For instance, take a sun-spot, in which the usual brilliancy of the sun in the other parts of its disc is altogether wanting. There is not only great darkness here and there, but wonderful turnings and twistings and bendings of this solar envelope, which I have already told you Kirchhoff asserts to be a liquid one, but which I think a little consideration of Fig. 50 will show you is more probably gaseous, or cloudy, than liquid. It is obvious, I say, in this case that there was a great probability of the spectroscope being able to tell us something about this absence of light, for an absence of light means one of two things; it means either that there was a defect in radiation, or that there was some excess of absorption, and I may say that this difference—which I hope you now all thoroughly understand—really formed the battle-ground between the English and French astronomers until a few years ago. Long after Kirchhoff's experiment, M. Faye, a distinguished member of the Institute of France, went all over the work again, and declared that the sun-spot was dark, because we there got the light, not from the brightly shining envelope, but from some feebly radiating gas inside the sun; that the sun was a gigantic bubble, the bubble being nothing else than the photosphere—the liquid sphere of Kirchhoff—the interior being composed of gas, glowing at such an enormous temperature that the light we got from it was extremely feeble. You will see in a moment that, if the sun-spot were really due to the radiation from gas, we should get from that sun-spot a selective spectrum, that is to say, a spectrum with bright lines. The English astronomers said: "No; a sun-spot is not due to defective radiation at all; there is something over the bright portion of the sun which eats away the light:" whether the light was eaten away generally—whether, in fact, we had an instance of general or selective absorption—was not stated, but what they did distinctly state was, that the sun-spot was simply an indication of absorption. So that, you see, here was a thing which a spectroscope might settle almost at once, provided always that a good sunspot could be obtained for the experiment. This was done in 1866. Fig. 51 gives an idea of what is seen when we observe a small sunspot, and it is one which is full of meaning. Here is a very clear image of the solar spectrum near the double line D, and also the double D itself. If it were possible to have given you the whole of the sun's spectrum on the same scale as this, it would require an engraving yards in length, but it would be almost impossible to make my meaning clearer than I hope I can do by this small portion; and I must therefore ask you to take for granted that the dark line which you see running along this yellow portion of the spectrum would really run along the whole length of the spectrum, from the extreme red to the extreme violet. This, then, you see in a moment, was an indication of general absorption; that is to say, in the way in which the light is affected by its passage through the prism, we have the problem settled in an instant, that a sunspot is due to general absorption at all events. Further, in observing the spectra of different sunspots, it was found that the spectrum of the middle of the sunspot is much darker than the outside. So that you see this simple experiment tells us not only that the sunspot is due to general absorption, but that there is more general absorption in the middle of the spot than at its edge. This is the way in which this little prism is able to deal with these great problems.

J. NORMAN LOCKYER

(*To be continued.*)

MIND IN THE LOWER ANIMALS

I RECENTLY received a letter from Mons. J. C. Houzeau, the author of the "Études sur les Facultés Mentales des Animaux comparées a celles de l'Homme," published at Mons, Belgium, in 1872, and reviewed by Mr. Wallace in NATURE of October 10, 1872. The latter eminent writer asserts that M. Houzeau's work "contains a mass of curious facts, acute observations, and sound reasoning, which fully entitle its author to take high rank among philosophical naturalists" (p. 471). I quite agree with him in his estimate of M. Houzeau's labours, being disposed to place his two volumes of "Études" on a par with the works of Mr. Darwin; and with another work, which, while little, if at all, known in this country, deserves, nevertheless, the highest consideration at the hands of all interested in comparative psychology—the "Traité de la Folie des Animaux de ses Rapports avec celle de l'Homme," by Dr. Pierquin, published in Paris (in 2 vols.), so long ago as 1839.

I need not say that any suggestions coming from an observer of such experience as M. Houzeau deserve the attention of the now many earnest students of the subject of "Mind in the Lower Animals;" and I therefore make no apology for bringing under the notice of your readers certain remarks contained in the letter aforesaid.

In the first place, M. Houzeau begs to direct attention to "the high importance of sparing—at least for observation—what remains of anthropoid animals in Asia and Africa. It is my deep regret that there are none in the country where I live" (Jamaica); "and that I am thereby deprived of an opportunity to study them. They should be tamed, domesticated, and studied in their own climate—at home. The gorilla, for instance, should be perpetuated in Guinea in domesticity. As I stated in my book, it does not appear impossible that apes might learn to talk. Should the attempt succeed even partially, what would not be the bearing and importance of it physiologically and historically? Could not some means of study be devised in the English colonies? To save the Anthropoids from destruction, and to promote the study of their mental capacity, is worthy surely of the earnest exertions of naturalists."

I quite concur with him as to the desirability of educating by domestication—so far as possible, and studying the results of such education in the anthropoid apes, and indeed the whole group of the Quadrumana. We know what has been the result in the dog of centuries of association with, and training by, man; though even in that familiar animal we do not yet know the extent of his capabilities, because training in certain directions has scarcely been attempted. Man has, for his own ends, directed special attention and effort to the development, in the dog, of his power of scent, swiftness, vision, courage, watchfulness, and other qualities that render him useful in the chase, as a watch-animal, as a companion, and so forth. But no similar persistent efforts have been made to cultivate, for instance, his moral sense—to produce an animal good in a moral point of view—honest, affectionate, benevolent, conscientious, in the highest degree. And yet that it is quite as possible to produce or educe moral greatness or goodness as physical swiftness or muscular strength, I am firmly persuaded. Notwithstanding all that has been said of the superior intelligence of the dog, horse, elephant, ant, and bee, I believe that were as much care bestowed on the training of the moral qualities of many monkeys or apes as is given to the instruction of the pointer or setter, the homing pigeon, piping bullfinch, or talking parrot, or to the training of the race-horse, results of a startling kind would be attained, or would be shown to be attainable. There are certain respects in which apes and monkeys approach more closely to man than do the dog or the other animals just mentioned: they possess potentialities or capabilities of which some of the almost marvellous stories told us by reputable traveller-naturalists give us but a glimpse.

I cannot, however, discuss that or other subjects in comparative psychology here, hoping, as I do, to have fuller and more fitting opportunity in a forthcoming volume of the "International Scientific Series" of Messrs. H. S. King and Co.

M. Houzeau expresses surprise that, at the present day, the belief should be almost universal that, while all races and conditions of man have souls, the best of other animals have none. This is obviously a matter of pure speculation, which I must not now discuss. But I may direct the attention of your readers to a curious book published in Aberdeen in 1824, by Peter Buchan, entitled, "Scriptural and Philosophical Arguments or Cogent Proofs from Reason and Revelation that Brutes have Souls, and that their Souls are Immortal." The work in question is, however, now so rare, that it may be difficult to obtain even a perusal of it. The reader of German literature may also refer to a book on the same subject by Schmarda, to which my attention was called some time ago by the late Professor Day, of St. Andrews.

M. Houzeau animadverts on the anomaly that the persons, from whom we should expect the most valuable evidence regarding the mental acquirements or capacities of the lower animals—those who are habitually and intimately associated with them—drovers and drivers, horsemen and huntsmen, shepherds and sportsmen, jockeys and grooms, butchers, and even veterinarians, are those, on the contrary, in whom we too frequently meet with the strangest ignorance or prejudice. They would seem to be, as a rule, incapable of honestly observing and of making logical inferences from facts observed; instead of using their own eyes and reason, they permit themselves to be blinded and befooled by obsolete tradition or fable.

Notwithstanding the perfectly overwhelming bulk and variety of the literature of comparative psychology—or at least of the data on which it may be founded, there are many points in the mental history of the lower animals that require and admit of elucidation by *observation and experiment*. If any person of ordinary intelligence—either abroad or at home—feels inclined to plead, as an excuse from contributing to the progress of comparative psychology, the want of proper opportunity, I would commend to his consideration the example of M. Houzeau as a noble one of the successful "pursuit of knowledge under difficulties." He modestly describes himself as a traveller-naturalist: and in the letter above referred to thus refers to the circumstances under which he collected the materials for the two bulky volumes of *Études*, that constitute one of the most important contributions yet made to the science of comparative psychology. "It was rather occasionally that my attention was called to the subject of the 'Mental faculties of animals,' having been almost exclusively engaged, previous to my sojourn in America, in astronomical and geographical pursuits. Still the subject was pressed upon me when, in the wildernesses of Texas and Northern Mexico, I had to live in the open air, in the constant company of domestic animals and in close proximity to wild ones; far away," as he says, "from the European field of labour and even from intellectual resources," in a foreign wild land, without the means of literary or scientific reference. Under circumstances, in a word, most unfavourable to such a publication, he has nevertheless produced a work that would do honour to any of our own *savans*, with all the appliances of our large cities, large societies, and large libraries at their command.

W. LAUDER LINDSAY

NOTES

FREE admission to the lectures and courses of practical instruction in Chemistry, Physics, Mechanics, and Biology at South Kensington will be granted to a limited number of Teachers and Students of Science Classes under the Science and Art Department, who intend to become Science Teachers. The selected candidates will also receive a travelling allowance, and a maintenance allowance of 1*l.* 1*s.* per week, while required to be present in London. The course in Chemistry will commence in October, and end in the following June. The course in Biology will commence in October and close in February or March. The course in Physics will commence about February and close in June. The course in Mechanics will probably commence about February and close in June. Students are required to attend from 9 or 10 A.M. to 4 or 5 P.M. daily, in addition to the time required in the evening for writing up their notes, &c. Candidates for these Studentships must send in their applications on Science Form No. 400, copies of which may be obtained on application to the Secretary of the Science and Art Department. For the courses in Biology and in Mechanics some power of drawing is essential, and no candidate will be admitted who cannot show that he has acquired sufficient power.

THE following courses of instruction of Science Teachers in connection with the Science and Art Department will probably be organised this summer :—1. Chemistry, Inorganic, 2. Chemistry, Organic, 4 weeks, commencing July 1, Prof. Frankland, F.R.S. 3. Magnetism and Electricity, 3 weeks, commencing June 24, Prof. Guthrie, F.R.S. 4. Heat and Light, 3 weeks, commencing July 17, Prof. Guthrie, F.R.S. 5. Botany, 4 weeks, commencing June 24, Prof. Thiselton Dyer. 6. Mechanics, 4 weeks, commencing June 25, Prof. Goodeve. 7. Geometrical Drawing, 3 weeks, commencing June 26, Prof. Bradley. Before definite arrangements can be made, however, it is necessary to know how many Teachers can and will take advantage of the courses ; and therefore all Teachers who wish to attend are required to fill up and return a form (Science Form, No. 500), which may be obtained by application to South Kensington. If more Teachers apply to attend than can be accommodated at any course, those will be selected who have passed the highest examinations—in which the result of the present May Examination will be counted—and have had the most successful classes. The Teachers who are selected, and who attend one or more of the courses, will receive 2nd class railway fare and 30*s.* a week while in London.

IN connection with St. John's College, Cambridge, there will be offered for competition, in December 1873, an Exhibition of 50*l.* per annum for proficiency in Natural Science, the Exhibition to be tenable for three years in case the Exhibitioner have passed within two years the previous examination as required for candidates for honours ; otherwise the Exhibition to cease at the end of two years. Candidates will have a special examination in (1) Chemistry, including practical work in the laboratory ; (2) Physics (viz., Electricity, Heat, Light) ; (3) Physiology. They will also have the opportunity of being examined in one or more of the following subjects :—(4) Geology ; (5) Anatomy ; (6) Botany ; provided that they give notice of the subjects in which they wish to be examined four weeks prior to the examination. No candidate will be examined in more than three of these six subjects, whereof one at least must be chosen from the former group. It is the wish of the Master and Seniors that excellence in some single department should be specially regarded by the candidates. They may also, if they think fit, offer themselves for examination in any of the classical or mathematical subjects. Candidates must send their names to one of the tutors fourteen days before the commencement of the examination. The tutors are the Rev. S. Parkinson, D.D., Rev. T. G. Bonney, B.D., and J. E. Sandys, Esq., M.A.

FROM Prof. E. D. Cope we have received the description of two apparently new fossil mammalian forms from the Eocene of Wyoming, which he places among the Carnivora. *Mesonyx obtusidens* forms, according to the author, a distinct family of the fissiped Carnivora, most closely related to the Canidæ, with weakly sectorial teeth, four of them being true molars (a marsupial character), and short, flattened, ungual phalanges in which there are no indications of collars for the reception of the nails themselves. *Synoplotherium lanius* may be a Carnivore, but the claws were flat, and the scaphoid of the carpus did not anchylose with the lunare, which shows that it belongs to a more generalised type. It must be remembered that Prof. Marsh has described very similar forms from the same strata.

MESSRS. WILLIAMS AND NORGATE have just issued the prospectus of a unique and most elaborate work by Mr. Herbert Spencer, consisting to a large extent of the tabulated material which he has accumulated for his "Principles of Sociology." In preparation for the latter work, requiring as bases of induction large accumulations of data, fitly arranged for comparison, Mr. Herbert Spencer, some five years ago, commenced, the collection and organisation of facts presented by societies of different types, past and present. Though this classified compilation of materials was entered upon slowly to facilitate his own work, yet, after having brought the mode of classification to a satisfactory form, and after having had some of the tables filled up, the results appeared likely to be of such value that Mr. Spencer decided to have the undertaking executed with a view to publication : the facts collected and arranged for easy reference and convenient study of their relations, being so presented, apart from hypotheses, as to aid all students of Social Science in testing such conclusions as they have drawn and in drawing others. The work consists of three large divisions. Each comprises a set of tables exhibiting the facts as abstracted and classified, and a mass of quotations and abridged extracts, otherwise classified, on which the statements contained in the tables are based. The condensed statements, arranged after a uniform manner, give at one view, in each table or succession of tables, the phenomena of all orders which each society presents—constitute an account of its morphology, its physiology, and (if a society having a known history) its development. On the other hand, the collected extracts, serving as authorities for the statements in the tables, are (or rather will be, when the work is complete) classified primarily according to the kinds of phenomena to which they refer, and secondarily according to the societies exhibiting these phenomena ; so that each kind of phemonenon, as it is displayed in all societies, may be separately studied with convenience. The three divisions, each thus constituted, comprehend three groups of societies :—(1) *Uncivilised Societies* ; (2) *Civilised Societies—Extinct or Decayed* ; (3) *Civilised Societies—Recent or still Flourishing*. Several sample tables have been sent us, and as a specimen of the classifactory headings under which the immense array of facts are grouped, we shall give those belonging to Table IX. of Division I. ("Uncivilised Races"), the Sandwich Islanders, one of the Malayo-Polynesian Races. First are given their Inorganic Environment (Climate, Surface) ; Organic Environment (Vegetal, Animal) ; Sociological Environment (adjacent tribes), Physical, Emotional, and Intellectual Characters. Then follow the tables, divided into Structural and Functional, each of which is subdivided into Operative and Regulative. The Structural Operative is again subdivided into Operative and Regulative ; the Structural Regulative is subdivided into Political (*Civil*, [Domestic, (Marital, Filial), Public], *Military*), Ecclesiastical, and Ceremonial (*Mutilations, Funeral Rites, Laws of Intercourse, Habits and Customs*). Under Functional, the Regulative is subdivided into Sentiments (*Æsthetic, Moral*), Ideas (*Superstitions, Knowledge*), and Language ; the Operative into Processes (*Distribution, Exchange, Production, Arts, Rearing*, &c.), and Products (*Land-Works, Habitations*, &c., *Food, Clothing, Implements, Weapons, Æsthetic Products*). Under each final subdivision ample details are given. The value of such a work to all students of sociology, and of mankind generally, will be inestimable.

SIR JOSIAH MASON, who has already built and endowed an orphanage at Erdington, near Birmingham, at a cost of more than a quarter of a million, has now arranged to erect and endow a Scientific College in Birmingham, for which will probably be expended at least an equal amount. The *Times* gives the following details :—During his long experience as a manufacturer, Mr. Mason became deeply convinced of the want of and necessity for "thorough systematic scientific instruction, specially adapted to the practical, mechanical, and artistic requirements" of the Midland district, and to this want he has determined to devote a portion of his remaining property to supply. The institution is to be called "Josiah Mason's College," or "Josiah Mason's College for the Study of Practical Science." Regular systematic instruction is to be given in mathematics, abstract and applied phy-

sics, both mathematical and experimental; chemistry, theoretical, practical and applied; the natural sciences, especially geology and mineralogy, with their application to mines and metallurgy; botany, and zoology, with special application to manufactures; and physiology, with special reference to the laws of health. The English, French, and German languages will also be taught. The trustees have power to include mechanics and architecture and all other subjects necessary to carry out the objects of the founder. Mere literary education and instruction are excluded, as well as all teaching of theology and subjects purely theological. No principal, professor, teacher, or other officer of the college is ever to be called upon to make any "declaration as to or submit to any test whatever of their religious or theological opinions," nor are these in any wise to be considered either as qualifications or disqualifications for holding any office, fitness to give the instruction required being the sole and only test. Provision is also made for giving lectures and opening classes for popular or unsystematic instruction, at which the attendance shall be open to all persons, "without distinction of age, class, creed, race, or sex." The founder's object being to promote the prosperity of the manufactures and industry of the country, especially of the two towns so frequently named, the college will be open to qualified persons of all classes who have to rely on science, art, or manufactures for a livelihood, "especially the more intelligent youth of the middle class." Provision is also made, when the funds permit it, to provide instruction for females as well as males. The site selected for the college is in the centre of the town, and the land is therefore of the greatest value, and the generous founder has already laid out upwards of 20,000*l*. on the site. He has also conveyed landed property producing about 600*l*. a year, and there is a clause in the deed in which he states it to be his intention to devote by his will additional funds for the use of the college. The total amount of this noble endowment cannot, therefore, be positively stated, as it will, of course, depend upon circumstances. Enough, however, has already been done to render the "Josiah Mason College" one of the most princely gifts yet made to posterity in England by any of her wealthy sons.

THE forthcoming number of Petermann's *Mittheilungen* will contain an interesting article compiled from the Australian papers, giving an account of a three months' journey during August, September, and October of last year into the interior of Australia, by Mr. Ernest Giles, accompanied by Messrs. Carmichael and Robinson. They struck off from the route of the overland telegraph at Chambers's Pillar, about 133° 55′ E. long., and 24° 53′ S. lat., and journeyed in a north-west direction along Finke Creek, traversing ground which has not hitherto been explored. They passed among long ranges of hills, lying in an east and west direction, and varying in height from a few hundreds to 4,000 ft., though few of the heights are apparently above 1,000 ft. At about the 24th parallel, in 133° N., they came upon multitudes of magnificent fan palms growing along the bed of the creek; they named the place the "Glen of Palms." Their journey in this direction extended to 129° 55′ W., and about 23° 10′ S., the utter sterility of the region and the want of water compelling them to turn back. It was only during the last few days, however, of their western journey that water became scarce. The most characteristic vegetation throughout was Spinifex; Casuarina was also of frequent occurrence. Travelling for about 100 miles in a southern direction, the explorers came upon an extensive salt marsh, apparently from Petermann's map upwards of 100 miles long and from 6 to 7 miles broad; Baron von Müller has named this Amadeus Lake. After staying here for a few days, Giles and his companions struck northwards for about 40 miles, and then south-eastwards, passing numerous creeks and a range of hills, "Gill Range," and meeting the Finke again on November 16, not far from their starting-point. Altogether these plucky explorers travelled 1,300 English miles, and have added considerably to our knowledge of the interior of Australia.

UNDER the name of "Herbarium Mycologicum Œconomicum," F. Baron Thümen proposes to form a collection of those parasitic fungi which are injurious (including, also, any that are useful) in forestry, agriculture, horticulture, or in any other branch of industry. The specimens of each species will be labelled with the scientific name, diagnosis, and any needful remarks, and, where possible, will be sufficiently numerous for a portion to be submitted to microscopic examination. The collection will be issued in fasciculi of fifty species, at the price of three thalers each, and may be obtained of the collector, at Teplitz, in Bohemia.

WE regret to learn that Mr. Louis Fraser, at one time prominently connected with the Zoological Society of London, author of the "Zoologia Typica," and a professional taxidermist of high repute, is suffering from destitution, in his old age, in British Columbia. On April 7 last a communication was presented before the meeting of the Academy of Sciences of San Francisco on this subject by Mr. Henry Edwards, one of the members, and an appeal for assistance was made to the friends of science. This was answered by contributions on the part of several persons, but it is not stated to what extent.

THE anniversary meeting of the Royal Geographical Society was held on Monday, Sir Henry Rawlinson in the chair. Sir Bartle Frere was elected President, and the Earl of Derby, Sir H. Rawlinson, Sir R. Alcock, and Admiral Richards, vice-presidents. The retiring president, in his valedictory address, reviewed at some length the progress of scientific exploration during the past year.

AT the special request of Rear-Admiral Sands, the U.S Congress, at its last session, allowed an appropriation for the purpose of completing and publishing the catalogue of southern stars, observed by Gilliss in 1850–52, and the work is now being put in the hands of computers for publication as soon as possible.

A SLIGHT shock of earthquake was felt on the morning of April 14, at Goalparah, Assam.

ADDITIONS to the Brighton Aquarium during the past week: Smooth Hound (*Mustelus vulgaris*); Skate (*Raja batis*); Gurnards (*Trigla lyra*); John Dorée (*Zeus faber*); Scad, or Horse Mackerel (*Trachurus trachurus*); Lump-fish (*Cyclopterus lumpus*); Turbot (*Rhombus maximus*); Common Carp (*Cyprinus carpio*); Gold and Silver ditto (*Carassius auratus*); Tench (*Tinca vulgaris*); Herrings (*Clupea harengus*); Sharp-nosed Eels (*Anguilla vulgaris*); Sand-launce (*Ammodytes lancea*); Garfish (*Belone vulgaris*); Zoophytes, *Actinoloba dianthus*, *Tubularia indivisa*, *Sertularia cupressina*, *Obelia geniculata*, *Pleurobrachia pileus*.

THE additions to the Zoological Society's Gardens during the past week include two Cretan Ibexes (*Capra picta*), presented by Mr. T. B. Sandwith; a Macaque Monkey (*Macacus cynomolgus*); a Rhesus Monkey (*M. erithraeus*) from India, and a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, presented by Mr. H. N. Hewett; a dark-green Snake (*Zamenis atrovirens*). and a four-lined Snake (*Coluber quadrilineatus*) from Malta, presented by Mr. C. A. Wright; a pig-tailed Monkey (*Macacus nemestrinus*) from Java; a Malabar Parrakeet (*Palaeornis columboides*) from South India; an olive Weaver Bird (*Hyphantornis capensis*), from South Africa, purchased; a Brazilian Tapir (young) (*Tapirus terrestris*) from South America; a Harpy Eagle (*Thrasaëtus harpyia*) from South America, deposited; four variegated Sheldrakes (*Tadorna variegata*), and four ruddy Sheldrakes (*T. rutila*) hatched in the Gardens.

SCIENTIFIC SERIALS

Poggendorff's Annalen der Physik und der Chemie. No. 3, 1873.—This number commences with a paper by Dr. Oudemans, jun., on the influence of optically inactive solvents on the rotatory power of optically active substances. The author, employing a Wild polarlstrobometer and lime-light, experimented with cane-sugar, cinchonin, brucin, phlorizin, and other substances, with water, chloroform, alcohol, ether, &c., as solvents. He unexpectedly found that the specific rotatory power of cinchonin in various mixtures of alcohol and chloroform had not values entirely intermediate between those of cinchonin in either solvent separately (which are ⤈ 212° and ⤈ 228°). It rises to a maximum of over ⤈ 237° in a mixture of 10 per cent. alcohol and 90 per cent. chloroform. He further compared the influence of different solvents on the specific rotatory power of active substances, with their solvent action, and he considers the greater values of the former property correspond with a greater solubility of the active substance. The numerical results are given in full.—Julius Thomsen continues his "Thermochemische Untersuchungen," examining, in this paper, the affinities of the constituents of water, of sulphuretted hydrogen, of ammonia, and of carburetted hydrogen. He finds that while there is development of heat in the formation of marsh gas, there is absorption in the formation of ethylene and acetylene, from carbon and hydrogen. The author gives a *résumé* of results from the series of researches here terminated (the affinity of hydrogen to the metalloids), which presents some points of considerable interest.—In the next paper Prof. Lubimoff of Moscow calls attention to an error current in most text-books on physics. The field of view in a Galilean telescope is stated to depend on the size of pupil of the observer's eye, and to be measurable by the angle under which this will appear from the centre of the object-glass. This, he says, gives a value five or six times smaller than the actual, which is directly dependent on the size of aperture of the object-glass. He explains and illustrates his new theory at some length.—F. Rüdorff contributes the first part of a paper on the solubility of saline mixtures, and Ed. Ketteler continues his mathematical inquiry into the influence of astronomical motions on optical phenomena.—Among the extracted papers may be specified those by Edlund on galvanic resistance, by Braun on direct photography of the solar protuberances, and by Baumhauer on hygrometry in meteorological observatories.

Der Naturforscher for April 1873, contains a large amount of varied and interesting scientific matter. In Physics and Chemistry, there are short accounts of M. Jamin's researches on condensation of magnetism, Dr. Mayer's on measurement of sound, M. Cornu's new method of determining the velocity of light, Herr Feddersen's paper on thermo-diffusion of gases, Herr Nasse's on the nitrogen in albumenoids, Clerk-Maxwell's lecture on action at a distance, &c. Herr Nasse finds that, in the albumen-molecule, one portion of the nitrogen is combined loosely, another much more intimately, and he sets himself to determine the proportion of loosely-combined to the entire nitrogen-contents, in various albuminous substances. His observations have an important physiological bearing. In biology proper, we may note a paper giving the results of Herr Stohmann's recent study on animal nutrition. This author endeavours to formulate mathematically the digestibility of food stuffs. P. Secchi's recent communication on the solar protuberances and spots is given, and there is a meteorological paper on the temperature of air in woods and in the open, describing experiments by Herr Ebermayer. We may further call attention to a note on Baranetzky's experiments on the periodicity of outflow of sap in plants, a phenomenon he finds based on the periodical action of light. Geology, geography, technology, &c., are also represented in this serial, and the weekly "Kleinere Mittheilungen" furnish a number of well-selected scientific data.

SOCIETIES AND ACADEMIES

LONDON

Geological Society, May 14.—Mr. Joseph Prestwich, F.R.S., vice-president, in the chair.—The following communications were read.—"On the genus *Palæocoryne*, Duncan and Jenkins, and its affinities," by Prof. P. Martin Duncan, F.R.S.—In this paper the author referred to certain minute fossils from the Carboniferous rocks of Scotland, described by himself and Mr. Jenkins in a paper read before the Royal Society, as belonging to the Hydroida, and most nearly resembling the recent genus *Bimeria*, Wright. He stated that numerous specimens since received threw some further light on the nature of these fossils, and showed especially that in all probability the base is not really cellular, but that the cellular appearance is produced by the growth of the real base of the polype over the cells of the *Fenestella* on which it grows.—"Notes on Structure in the Chalk of the Yorkshire Wolds," by Mr. J. R. Mortimer.—In this paper the author described a peculiar structure observable in chalk from Yorkshire and elsewhere, giving it a striated appearance. This structure had been ascribed by Dr. Mackie and others to slickensides. The author adduced reasons for doubting the mechanical origin of these striations, and argued that they are of an organic nature. He ascribed them to corals, and remarked that similar striæ occur in all limestone formations.—"On *Platysiagum sclerocephalum* and *Palæospinax priscus*, Egerton," by Sir P. de M. Grey-Egerton, Bart., M.P., F.R.S.—The two species of fossil Fishes noticed in this paper were described by the author in the 13th Decade of the Memoirs of the Geological Survey, published in 1872. They are both from the Lias of Lyme Regis. He now described some new specimens which add to our knowledge of their characters. An example of *Platysiagum* shows the position of the dorsal fin, which is placed very far back, occupying a place opposite to the interval between the ventral and anal fins, and the form of the trunk, which is of nearly uniform depth from the occiput to the base of the dorsal fin. The structure of the dorsal fin was described in detail. The new specimen of *Palæospinax priscus* shows especially the position of the second dorsal spine, which is placed over the 50th vertebra, the first being on the 16th, the fish thus most nearly approaching the existing *Cestracion*, which it also resembles in its dentition. In other respects it seemed to be most clearly allied to *Acanthias*.—"On a new genus of Silurian Asteriadæ," by Mr. Thomas Wright, F.R.S.E.—The specimen described showed the outline of a small Starfish, with a large disc and short rays, in a slab of Wenlock Limestone from Dudley. The outline of the ten rays was described as marked out by the border of small triangular spines, the other plates of the disc and rays being absent. Each ray was terminated by a stemlike multiarticulate process as long as the ray, from towards the extremity of which spring slender lateral processes, giving it a tufted appearance. This Starfish, which is in the collection of Dr. Grindrod, is named by the author *Trichotaster plumiformis*.

Zoological Society, May 20.—Dr. E. Hamilton, vice-president, in the chair.—Lord Arthur Russell exhibited specimens of, and made remarks upon, the different varieties of the Carp (*Cyprinus carpio*) cultivated in the German fish-ponds.—Mr. Sclater offered some remarks upon the most interesting animals observed in the Gardens of some of the continental Zoological Societies which he had lately visited.—Dr. E. Hamilton read a note confirmatory of the extraordinary fecundity of the Chinese Water-Deer (*Hydropotes inermis*).—Mr. H. E. Dresser exhibited some rare birds from the Ural, amongst which were the Smew (*Mergus albellus*) in down, nestlings of the Rustic Bunting (*Emberiza rustica*) and several specimens of Lilljeborg's *Salicaria magnirostris*, which last he believed to be identical with *Acrocephalus dumetorum* of India.—Sir Victor Brooke, Bart., read a paper on the African Buffaloes, which he considered might be reduced into two species, *Bubalus caffer* and *Bubalus pumilus*. Of these the latter exhibited two varieties in the western and eastern points of its range, while the former appeared to extend from the Cape up the eastern coast to Abyssinia without any material variation.—Mr. St. George Mivart, F.R.S., read a memoir on *Lepilemur*, *Cheirogaleus*, and other Lemurine forms, to which were appended remarks on the Zoological rank of the Lemuroidea in the natural system.—Messrs. Sclater and Salvin communicated a paper on some Venezuelan Birds collected by Mr. James M. Spence, amongst which were examples of two species believed to be new to science, and proposed to be called *Lochmias sororia* and *Crypturus cervinivientris*.—A communication was read from Mr. R. Swinhoe, on the White Stork of Japan, which he referred to a species different from the *Ciconia alba* of Europe, and proposed to call *C. boyciana*.—Mr. H. E. Dresser read some notes on certain oriental species of Eagles (*Aquila*).

Royal Horticultural Society, May 16.—General meeting, —Viscount Bury, M.P., president, in the chair.—The resignation of the Assistant-Secretary was announced.—The Rev. M. J. Berkeley, who was then called to the chair, commented on the

plants of interest exhibited. He called attention to specimens of *Cytisus Adami*, believed to be a graft-hybrid, which bears upon the same branches, besides its own proper intermediate flowers, the dissociated very distinct flowers of its parents.—*Tillandsia ionantha* and a large flowering specimen of *Cycas revoluta* were also alluded to.

Scientific Committee.—Dr. J. D. Hooker, F.R.S., C.B., in the chair.—Mr. Anderson-Henry sent cuttings from black currant bushes, the buds of which were swollen to an unusual size, but abortive. This was due to the presence of a four-legged acaroid, similar to those on lime and hazel. In gardens near Greenock it was seriously affecting the cultivation of the fruit; it is believed there to have been imported with plants obtained from the Low Countries.—A letter from Mr. Andrew Murray to Mr. Berkeley was read, dated Salt Lake City. He sent an *Oscillatoria*, which he had found in a hot sulphuretted spring; also specimens of a *Nostoc*, with very large-celled chains, which blackened the stones in the brooks.—Dr. Masters called attention to a mode of propagating the vine described by M. Rivière. Cuttings were planted vertically in the ground in the spring, the uppermost bud being completely covered with 3 to 4 inches of soil.

EDINBURGH

Royal Society, May 19.—Memoir on the placentation of the sloths, by Prof. Turner. After referring to the absence of any definite information on this subject in anatomical literature, the author described his dissection of the gravid uterus of a specimen of that species of two-toed sloth, which Peters has named *Choloepus Hoffmanni*. His specimen was perfectly fresh when it came into his possession, and he had succeeded in obtaining satisfactory injections both of the fœtal and maternal systems of blood-vessels. His dissections have led to the following conclusions:—The placenta of the sloth is not cotyledonary, in the sense in which the term is employed to express the non-deciduate placenta sub-divided into distinct and scattered masses, as in the ruminants. In the fullest sense of the word it is a deciduate placenta. If the inference which has been drawn from Sharpey's observations on the placenta in *Manis*, viz. that it is non-deciduate, be correct, then it is clear, if any value is to be attached to the placental system of classification, that the scaly ant-eaters can no long be regrouped along with the sloths in the order Edentata, which order must therefore be broken up. The memoir concluded with some remarks on the affinities, as regards their placental form and structure, of the sloths to the other deciduate mammals.

PARIS

Academy of Sciences, May 19.—M. de Quatrefages, president, in the chair.—The following papers were read.—A note on solar cyclones, with an answer, by S. Respighi to M. Vicaire and Father Secchi, by M. Faye. M. Vicaire in his late critique on M. Faye's solar spot theory had asked how that author could compare the barometric depressions in terrestrial cyclones which only amount to a few millimetres of mercury with the enormous lowerings of the chromosphere which ought to take place on the solar spots but which are inadmissible. M. Faye now replied that these depressions are *facts* long and carefully observed by Respighi, and quoted a letter from him on the subject. With regard to Secchi's assertion that Respighi had been deceived by the small size of his telescope ($4\frac{1}{2}$ inches aperture) he pronounced the objection utterly invalid, for, whatever might be the shortcomings of the telescope as regards minute details, it could never make the chromosphere appear very low where it was in reality very high.—Note on the mechanical properties of different bronzes, by M. Tresca.—Hydrologic studies of the Seine Part II., Agricultural applications, by M. Belgrand.—On the part played by the substratum in the distribution of rock lichens, by M. Weddell.—New observations on metallic deposits on zinc, &c., and a new heliographic process, by M. C. Gourdon.—On an electro-diapason of continuous movement, by M. E. Mercadier.—On an electro-dynamic experiment, by MM. G. Planté and Alf. Niaudet-Breguet.—On the action of dry ammonia gas on ammonic nitrate, by M. F. M. Raoult. The author found that the liquid produced by the action varies in composition with the temperature. At $-10°$ C., 100 grammes of the nitrate absorb 42·50 grammes of the gas; this gradually diminishes as the temperature rises until at $+29°$ 20·9 grm. only are retained and the product is solid, at 79° only 0·5 grm. of NH_3 remain.—On certain peculiarities observed in spectrum researches, by M. Lecoq de Boisbaudran.—On the preparation and properties of oxymalcic acid, by M. E. Bourgoin.—On the acid derivatives of napthylamine, by M. D. Tommasi.—On the different propylenic chlorides. A classification of the absorption-bands of chlorophyll; accidental bands, by M. J. Chautard. The author so calls the bands produced by the action of acids, alkalies, or other re-agents upon normal chlorophyll.—Observations on the regulation of the magnetic compass, by M. Caspari.—Experimental Researches on the influence of barometric changes on life, tenth note, by M. P. Bert.—Mineralogical determinations of the true meteoric irons (Holosidères) in the Museum, by M. Stan. Meunier. During the meeting an election to the vacant seat of the late M. le Comte Jaubert (Academecien libre) took place. M. de la Gournerie obtained 44; M. Breguet, 9; M. Sedillot, 5; M. Jacqmin, 2; and M. du Moncel, 1 vote. M. de la Gournerie was accordingly declared elected.

DIARY

THURSDAY, MAY 29.

ROYAL SOCIETY, at 8.30.—Croonian Lecture on Muscular Irritability after Systematic Death: Dr. B. W. Richardson

SOCIETY OF ANTIQUARIES, at 8.30.—Ballot for election of Fellows.

ROYAL INSTITUTION, at 3.—Light: Prof. Tyndall.

FRIDAY, MAY 30.

ROYAL INSTITUTION, at 9—On the Radiation of Heat from the Moon: The Earl of Rosse.

HORTICULTURAL SOCIETY, at 3.—Lecture.

SATURDAY, MAY 31.

ROYAL INSTITUTION, at 3.—The Historical Method: John Morley.

GEOLOGISTS' ASSOCIATION.—Excursion to Finchley.

MONDAY, JUNE 2.

ENTOMOLOGICAL SOCIETY, at 7.

ROYAL INSTITUTION, at 2.—General Monthly Meeting.

TUESDAY, JUNE 3.

ANTHROPOLOGICAL INSTITUTE, at 8.—On a ready method of measuring the Cubic Capacity of Skulls: Prof. Busk, F.R.S.—Flint Implements from St. Vincent's: Prof. Rollestoo, F.R.S.—Copy of a Mural Inscription in large Samaritan Characters from Gaza: Rev. D. I. Heath.—Strictures on Darwinism, Part II.: the Substitution of Types: H. H. Howorth.

ZOOLOGICAL SOCIETY, at 8.30.—The Antelopes of the genus *Gazella* and their Distribution: Sir Victor Brooke, Bart.—The Birds of the Philippine Islands: Viscount Walden.

ROYAL INSTITUTION, at 3.—Roman Archæology: J. H. Parker.

WEDNESDAY, JUNE 4.

MICROSCOPICAL SOCIETY, at 8.

THURSDAY, JUNE 5.

CONDENSED MILK

THE importance of milk as an article of diet is so great that anything offered as a substitute for it, or that renders it more available as food, demands attention. The composition of cow's milk is so nearly like woman's milk that the addition of a little water and sugar may be said to convert the one into the other; hence the practice of giving cow's milk to young children, and making it a substantial article of their diet long after they have cut their teeth and are able to masticate bread and meat. No inconsiderable quantity of milk is also consumed by adults, and its nutritive effect is not exceeded by any article of diet, as it contains all the constituents that are necessary to the perfect nutrition of the human body.

There are, however, several drawbacks in the use of cow's milk which diminish its utility, limit its use, and sometimes render it dangerous. One of the great drawbacks in milk is its liability to decomposition. The sugar it contains becomes acid, the caseine separates in the form of curd, and a fermentation ensues which renders it unpleasant and sometimes even dangerous as an article of diet. The latter effect is seen more particularly in young children. During the summer months they suffer extensively from diarrhœa, and there is little doubt that this is largely due to the acidity of the milk which is given to them. Milk bought in the morning in London is frequently unfit to be used in the evening for the diet of infants. These changes in milk are hastened by the present system of bringing milk to London from a distance in cans, by which means it is shaken, and its tendency to change hastened.

Another drawback in the use of milk is its liability to adulteration. Unfortunately the agent by which milk is adulterated, is easily accessible and can be detected with great difficulty. We cannot instruct cooks and poor people in the use of lactometers and hydrometers by which the learned test milk: moreover, the natural liability of milk to vary is very great. Thus the quantity of cream in milk received by the Aylesbury Condensed Milk Company varies from 9 to 17 per cent. Dr. Hassell states that the cream given by the milk of a cow, the milk of which he personally inspected, was but 4½ per cent. Although then all milk containing less than 9 per cent. of cream may be suspected of adulteration, yet it may happen that a milk containing but 4½ per cent. may be really not adulterated with water at all.

This varying quantity of cream also shows that even when milk is not adulterated it is liable to great variations in the quantity of cream which may be taken as the measure of its usefulness as an article of food.

Many attempts have been made to overcome these objections to the use of milk, and from time to time preparations of it have been sold by which freedom from acidity and adulteration are secured. The most available of these preparations have been those that submitted the milk to a process of evaporation by which more or less of the water naturally contained in milk is got rid of. By these processes the nutritive constituents of the milk are retained; the preparation keeps for some time, is easily conveyed from place to place, and by the addition of water milk, so to speak, is readily manufactured. None of these preparations, however, seemed to succeed till a process for making what is called "Condensed Milk" was introduced. Whether America or Europe has the honour of the invention we need not dispute here. It is now made in this country by thousands of gallons daily, and its manufacture may be witnessed on a large scale at Aylesbury.

Although the process of evaporating milk may be regarded as an exceedingly simple one, the attempt to carry it out at Aylesbury on a large scale has developed a complicated machinery in which steam power is extensively used; 200 persons are employed, and the milk of 1,200 cows, each yielding 14 quarts, is daily evaporated. The milk used is brought from farms in the neighbourhood in ordinary tin cans. Each can before it is sent to the factory is carefully tested by the taste and smell and the lactometer. Any doubtful specimens are set aside for re-examination or rejection. The milk is then passed into a vacuum pan, and the vapour thus produced is carried off and condensed and thrown away. When the milk has acquired a proper consistence it is mixed with sugar. This addition of sugar is the distinguishing feature of the condensed milk process. After this the milk is still further condensed till it reaches the required consistence, and is run off into the little tin cans which are so well known. The whole of these operations are carried out with a regard for cleanliness, which would look almost fastidious if it were not known that a single particle of decomposing milk allowed to get into the receiving pans might destroy the whole mass. Every can is returned thoroughly cleansed to the farmer who sends it, having been first submitted to hot water, then to a jet of steam, and then rinsed out by a jet of cold water.

The condensed milk thus prepared is of a semi-liquid consistence, and can be taken out of a jar with a spoon. Several analyses of this milk have been made. The late Baron Liebig found that it contained—

Water	22·44
Solids	77·56
	100·00

The *Lancet* has more recently published the following analysis:—

Moisture	25·10
Butter	11·73
Caseine	15·17
Milk sugar	16·24
Cane Sugar	29·46
Ash	2·30
	100·00

From these analyses it will at once be seen that the only perceptible difference between condensed milk and ordinary milk is that the former contains more sugar and less water than the latter. Both these things are necessary for attaining the objects for which condensed milk is manufactured. The diminution of the bulk of the water from 87 per cent. in ordinary milk to 25 per cent. in the condensed secures diminution of the bulk of the milk, and thus renders transportation comparatively easy. The condensed milk is easily converted to the condition of ordi-

nary milk by the addition of either cold or hot water. The addition of the sugar is found to be necessary, in order to enable the other constituents to resist decomposition. Milk will keep any length of time when entirely desiccated, but by the process of drying entirely the milk loses its flavour and many of its properties. The semi-liquid condition of condensed milk prevents these changes, but in this state it is liable to decompose; hence the necessity of additional sugar.

The question arises as to whether this added sugar in any way interferes with the quality of the milk in its relation to the diet of infants or invalids. In comparing human milk with cows' milk, we find that the latter contains more caseine and less sugar than the former. Hence, when given to children it is customary to add a little water and a little sugar to make it like mother's milk. This object is really effected by the addition of cane sugar to the condensed milk, and it may therefore be unhesitatingly employed in the nursery as a substitute for ordinary cows' milk.

After a personal inspection of the Aylesbury manufactory, and a full consideration of the whole subject, we are quite prepared to say that where good fresh cows' milk is unattainable, as it is almost practically so in our large towns, there is no substitute for it equal to condensed milk. Nor is this a matter of theory; hundreds of gallons are being used every day in London, and most of it under the direction of experienced medical men. One medical man assures us that he has a healthy, fine-grown child of ten months that has never taken anything but condensed milk.

As the diet of invalids, it may in some cases require watching when the action of sugar is injurious to the system: but in these cases milk should be altogether interdicted.

It is to be hoped that no disadvantage in the use of this agent has been overlooked, as the advantages of its use are so many and so obvious. It presents a pure form of milk in a condition in which it may be kept for any length of time, and is not injured by removal. It is always at hand night and day, and by the addition of cold or hot water can be converted into nutritious and wholesome food.

E. LANKESTER

THE PHYSIOLOGY OF MAN

The Physiology of Man. By Austin Flint, Jun., M.D. Pp. 470. (New York: D. Appleton and Co., 1872.)

WE have already had to speak in terms of high commendation of Dr. Flint's comprehensive treatise on human physiology, as being written in a clear, methodical, and judicial style, the statements made being carefully weighed, and in most instances supported, by the best, if not the most numerous, authorities; whilst the author has in many parts enriched it with the results of his own important researches. The present, which constitutes the fourth volume of the work, is no exception to our remarks. It is occupied with the consideration of the nervous system, excluding the special senses, and gives a very complete account of that difficult and extensive section of physiology, the study of which has engaged the attention of so many of the best workers in all civilised countries during the past twenty years. Dr. Flint commences by a short *résumé* of the principal facts that have recently been made out in regard to the structure of the nerve-centres and cords, and the mode of termination of the nerves in muscle, gland, and skin; entering into the subject perhaps as far as is necessary in a strictly physiological work, the author taking Schultze's article in the recently published "Handbook of Histology" of Stricker, Kölliker, and Robin as his guides. The first chapter concludes with an account of the recent observations of Voit on the regeneration of the cerebral hemispheres after their ablation, which show that a large portion of these bodies may be reproduced, and that the organ may recover its functions to no very inconsiderable extent.

The second chapter deals with the general functions of the motor and sensory nerves, and gives a very fair account of the history of the discovery of the difference in the function of the anterior and the posterior roots, due prominence being given to the claims of Walker, Mayo, and especially of Majendie. In speaking of the recurrent sensibility of the anterior roots, Dr. Flint is not satisfied with Brown-Séquard's explanation that it results from the compression of sensory nerves distributed to the muscles during the spasm caused by the irritation of the anterior roots; but inclines to Majendie's and Bernard's opinion that there are actually recurrent sensory nerves in the anterior roots, on the ground that the pain is sometimes apparently severe when the cramps are slight. The relations of the nervous system to electricity, and the rapidity of nerve conduction, with the means of estimating it, are well and correctly given.

The cranial nerves are next considered. In this section we think the author fails in his account of the deep origin of each nerve. He does not appear to have heard of or seen the papers of Lockhart Clarke contained in the Philosophical Transactions (1858-67). Yet these contain by very far the most minute and the most accurate descriptions hitherto published on these points, and the importance of their relations to pathology would have fully justified more elaborate details. Thus, to take one point only, whilst speaking of the deep origin of the sensory root of the fifth pair of nerves, he makes no allusion to the very interesting facts described by Clarke of the internal connection of this root with the vagus and glossopharyngeal nerves in the grey tubercle, or caput cornu posterioris; of the connection of its motor root with the glossopharyngeal nucleus and the fibres of that nerve, and with the fasciculus teres; or, finally, of the connection of the sensory root with the nucleus of the third through the intermediation of the grey tubercle, into which the sensory root penetrates. On the other hand, his account of the functions of the various nerves and their branches is given extremely well; the account of the chorda tympani, for example, being excellent; and the conclusion at which Dr. Flint has arrived, namely, that it is a nerve of gustation, as well as a motor or stimulant nerve for the submaxillary gland, being fully borne out by Lussana's observations recently published in Brown-Séquard's journal, and which, at the time Dr. Flint wrote, had not appeared. A very long section commensurate with its importance is devoted to the pneumogastric nerves, the action of which on the heart, larynx,

lungs, and stomach is given, with full reference to their remarkable inhibitory and depressing powers.

In the description of the anatomy of the spinal cord, Dr. Flint takes Gerlach's article in Stricker's Handbook as his guide, and gives the following as the results of his own experiments, and those of others which he regards as most reliable. "The gray substance is probably inexcitable and insensible under direct stimulus. The antero-lateral columns are insensible, but are excitable both on the surface and in their substance, *i.e.* direct stimulation will produce convulsive movements in certain muscles, which movements are not reflex and are not attended with pain. The lateral columns are less excitable than the anterior columns. The surface at least of the posterior columns is very sensitive, especially near the posterior roots of the nerves. The deep portions of the posterior columns are probably insensible, except very near the origin of the nerves." Dr. Flint then proceeds to describe the functions of the grey matter, and of the several columns of the white, explaining and adopting the views generally accepted. The posterior white columns he regards, with Todd, as containing fibres acting as commissures between the several segments of the cord.

The functions of the cerebrum are very briefly given, indeed, except in regard to *language* they are not given at all, and for a reason that scarcely appears satisfactory, viz. that though their consideration is properly a part of physiology, the range of the subject is so extensive, that it is only treated of exhaustively in special treatises on mental physiology. This is much to be regretted, as we feel sure that if Dr. Flint had attempted it, he would have succeeded in giving a very interesting section upon it. The cerebellum he regards as the co-ordinator of the muscular movements, and he has collected many pathological cases in support of his view. The last chapters are devoted to the sympathetic nerve and to sleep. The account of the sympathetic system enters freely into the consideration of the vaso-motor and trophic nerves. Upon the whole, this volume of Dr. Flint's work may be regarded as a valuable accession to physiological literature, and as giving the results of modern research with such fulness, combined with accuracy, that the ordinary student will not require to look beyond its pages for any information on this important subject of medical knowledge. We look forward with much interest to the next volume on the "Special Senses," which the author assures us is nearly ready.

CLODD'S "CHILDHOOD OF THE WORLD"

The Childhood of the World: a Simple Account of Man in Early Times. By Edward Clodd, F.R.A.S. (London: Macmillan and Co.)

THIS genial little volume is a child's book as to shortness, cheapness, and simplicity of style, though the author reasonably hopes that older people will use it as a source of information not popularly accessible elsewhere as to the life of Primitive Man and its relation to our own. In brief chapters he states the principal points of the modern science of civilisation, discussing the condition of Præhistoric savages, the early use of stone implements and the introduction of metals, the discovery of other useful arts, the evolution of language, the invention of writing, &c. Having laid down this as a foundation, he then proceeds to his main purpose, that of explaining the successive phases of man's belief, the working of inventive fancy in mythic legend, the rudimentary ideas of the lower races as to souls and their existence in a future state, the nature of deities, and the meaning of the worship offered to them by prayer and sacrifice. Examining the religions of the less cultivated races of the world, he passes through them to arrive at doctrines which, regarding them as highest and surest, he turns all his gift of earnest eloquence to teach. This book, if the time has come for the public to take to it, will have a certain effect in the world. It is not a mere compilation from the authors mentioned in the preface, but takes its own ground and stands by and for itself. Mr. Clodd has thought out his philosophy of life, and used his best skill to bring it into the range of a child's view. Why, indeed, should not children be taught their elementary philosophy of nature at the modern level? Why should they not begin to shape their lives by the best theory of the world, and their own place and duty in it, which their parents can accept? Thoughtful children will take in most of the facts Mr. Clodd works on, and his ideas will open many doors in their minds, leading into regions to be more fully explored years later. Much of the book, it is true, is beyond a child's unhelped understanding; not that the words are too hard, but that the ideas are. Its story is anything but "a tale of little meaning tho' the words be strong;" its simple language has often to convey thoughts too abstract for easy assimilation. Yet there is no harm in this, for the best children's books are those which in part engrave knowledge on their minds with finished accuracy, and in part only stamp roughly impressions which will take their sharper lines another time.

The world is growing daily more alive to the fact that the history of man and man's ideas, with all the problems of belief and duty which can be rightly treated on a historical basis, have been shifted into new places and altered into new forms by the modern sciences of the World and Man. At this present time there are numbers of parents and teachers to whose views such a modern "Religio Medici" as Mr. Clodd offers is congenial, and who distinctly want a book like his to teach out of. The need is all the more felt, because so many of the topics treated are among those where both theology and science put forward claims to speak with authority, while the adjustment of these claims has been mostly attempted by the class of writers who may be called "reconcilers." But educated people now distrust the method of these writers as vitiated by foregone conclusion, and it is more and more felt that the great problems of humanity must be dealt with by men who do not shape their evidence, but let their evidence shape them. Mr. Clodd, at any rate, is no "reconciler." It is evident that his religious feeling has come into real union with his positive knowledge, and that this act of mental chemistry has generated doctrines which are at once his theology and his philosophy. These doctrines it is not the office of this journal to discuss: nor, considering how far Mr. Clodd adopts (of course with due acknowledgment) evidence and theories from the heavier volumes of technical ethno-

logists, my own included, would it be convenient for me to enter into detailed argument on his ethnology. I need only mention as points to which exception is likely to be taken, Mr. Clodd's easy passing over of the really serious difficulty, what became of the bones of the Drift-men and Cave-men, and his too confident expressions as to the first habitat of man, and the Origin of Languages. This said, what is left for me is simply to announce his work, helping to make it known to the class of readers who are waiting for it. E. B. TYLOR

OUR BOOK SHELF

Notes on Natural Philosophy. By G. F. Rodwell, F.R.A.S., F.C.S., Lecturer on Natural Philosophy in Guy's Hospital and Science Master in Marlborough College. (London: J. and A. Churchill, 1873.)

THIS useful little work is an enlargement of Notes which the author had prepared for the students attending his lectures at Guy's Hospital. The title is perhaps a little too wide, as the book contains no reference to Sound and but a scanty treatment of Light, polarisation, for example, being not even mentioned. These omissions are explained in the preface as caused by the adaptation of the notes to the "Preliminary Scientific" Examination at the London University. We are quite sure, however, the author will agree with us that students for this examination will have to supplement their reading by some rather stiffer work than we find here. As an *introductory* text-book for this examination it is quite the best we have seen, the author having carefully avoided that atrocious system of giving candidates only just such knowledge as may help them to scrape through an examination. The evidence of conscientious labour which is conspicuous throughout the book makes us the more regret the incompleteness of these Notes. Even of the subjects treated it is obvious that in 160 pages, only the barest outlines of natural philosophy can be given. The "Notes" therefore chiefly consist of lucid and concise definitions, and everywhere bristle with the derivations of scientific terms. To this latter point the author has devoted much labour and thereby done good service to science; though on the other hand we cannot help thinking Mr. Rodwell runs a fair chance of being accused of pedantry by his frequent use of Latin quotations. One or two little points needing correction catch our eye. Fig. 18 is printed upside down; amidst all the derivations we do not see the meaning of the terms given to different thermometric scales; here as in some other books cobalt is erroneously stated to be attracted to a magnet even at the highest temperature. As this seems to be a frequent error we will give Faraday's own words on this matter: they are to be found on the very last page of his "Experimental Researches in Electricity." "By greater elevation (of temperature) nickel first loses its distinctive power at about 635° F., then iron at a moderate red heat, and cobalt at a far higher temperature than either, near the melting-point of copper." There cannot be a doubt that this little book will be of use to science teachers and science students.

Transactions of the Norfolk and Norwich Naturalists' Society, for 1872-73. (Norwich: 1873.)

THIS little volume contains some excellent papers. The president, Dr. Beverley, in his address, suggests, rightly, we think, that members of such societies ought, in their researches and papers, never to lose sight of the views and opinions usually associated with the name of Darwin, and very justly says that "the origin of species, the theory of evolution, and other Darwinian doctrines, cannot be proved or disproved by newspaper controversy or theological discussion." The first paper is by Mr. Howard Saunders, F.Z.S., on the Ornithology of Spain, which is followed by a short paper on *Vanessa Antiopa*, by Mr. C. G. Barrett. This is followed by a long, carefully compiled, and well illustrated list of the Fungi of Norfolk, by Mr. C. B. Plowright, M.R.C.S. The president, Dr. Beverley, also contributes a paper on the edible fungi of Norfolk, in which he draws attention to the great value of this much neglected source of nutritive food. There is an interesting paper on the Otter, by Mr. T. Southwell, F.Z.S. The two last papers are, one on the "Wild Birds' Protection Act," by Mr. H. Stevenson, F.Z.S., in which he points out the many obvious holes in the Act and adds a list of "wild birds," containing the most common provincial names by which they are known in England and Scotland; and Notes on the Mammalia of Norfolk, by Mr. T. Southwell. This society deserves the greatest credit for the important work its members are doing. They are making a praiseworthy, and so far a successful effort, to publish a fauna and flora of Norfolk. Already there have been prepared a list of the Mammalia and Reptilia, the Land, Freshwater, and Marine Shells, and, as we have above said, a list of the fungi. These will be followed by the Fishes, by Dr. Lowe; the Birds, by Mr. Stevenson (author of "The Birds of Norfolk);" the Flowering Plants and Ferns, by Mr. H. D. Geldart; Lepidoptera, by Mr. C. G. Barrett; all of which, we believe, are in hand, and will be published as the society finds funds to print them. Such a society deserves the greatest encouragement, and it is a pity that it should be hindered in its good work for want of funds. This ought not to be in a county like Norfolk, and we are sure that the intelligent inhabitants of that county only need to be made aware of the value of the work the society is doing, to come forward and lend it a helping hand. This they will best do by becoming members and taking as active an interest in the work as their circumstances permit. The society ought to take effectual means of making its aims and the value of its work be known throughout the county.

Birds of the Humber District. By John Cordeaux. (Van Voorst.)

MR. CORDEAUX is so well known as a careful and trustworthy observer of nature, that any work on his favourite subject, from his hand, must be read with interest. A residence of ten years in the district of which he writes, comprising North and Mid-Lincolnshire, and Holderness, has enabled him to gain a thorough familiarity with the times of appearance and departure of the birds which visit it. These points he has noted with great pains and precision, as is proved by the fact that he has been able clearly to trace the points of the district at which each of the migratory birds enter and depart, most doing so from the sea-coast, the grey wagtail, cuckoo, and common dotteril, being the only exceptions. The sections, of considerable length, devoted to the dates on which to expect the various wading birds, and the conditions of weather which cause these to vary, will be of great interest to sportsmen in the locality; the woodcock, snipe, and plover receive the fullest attention. Among the rare birds that are recorded as having been met with formerly, or of which one or more specimens have been shot lately, we find the cream-coloured courser, Macqueen's bustard (the only British example), Tengmalin's owl, and the tawny pipit. Most extraordinary of all is a jacamar in the collection of Canon Tristram, which was shot in 1849 by S. Fox, a gamekeeper, near Gainsborough; as the author remarks, "it must ever remain an ornithological puzzle how it could have reached this country." We recommend this excellent little work to all ornithologists and sportsmen.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Permanent Variation of Colour in Fish

A QUESTION of some interest is raised by a letter published by Mr. Saville Kent, in NATURE, vol. viii. p. 25. It is stated that a Plaice, now in the Brighton Aquarium, has "the posterior half of its under surface, usually white, coloured and spotted as brilliantly as the upper one; the line of demarcation between these two colours again, though sinuous, is most abrupt," and the writer proceeds to say that, on the Darwinian theory, this may be considered as a remarkable instance of reversion—"the Pleuronectidæ being derived from ancestors originally possessing bilateral symmetry, and an equal degree of coloration on each side."

First, as to the fact:—Examples of such colouring among the *Pleuronectidæ* are not very uncommon, and they occur most frequently in the Flounder (*Pleuronectes flesus*) and Plaice (*P. platessa*). Sometimes it is the upper surface which is thus affected—more or less of it being purely white. In a specimen now before me the colouring of the upper surface occurs upon the under one in numerous blotches of various sizes, and this mode of distribution is not uncommon. In every instance that I have heard of, the line or lines of demarcation, when they exist, are such as your correspondent describes, but, in extreme cases, no such line is present—the whole of one surface having uniformly assumed the colouring of the other. Such abnormal colouring may occur either upon the upper or lower surfaces; the fish in the former case being entirely white, and in the latter entirely brown.

The *rationale* offered by your correspondent, although engaging, is not unopen to criticism. For nothing can be more evident to Darwinists than that the colouring of the *Pleuronectidæ* has been acquired because of its protective adaptation to their peculiar form and habits. But it is difficult to see how such colouring could have conferred protection upon their free-swimming ancestors, so that, unless we make the highly anti-Darwinian supposition that the common progenitor was coloured in anticipation of the habits to be contracted by its offspring, there is only one hypothesis open to us, viz., that the unmodified progenitor adopted, through natural selection, the habit of lying on its side *because* of its original sandy colour. As this view, however, will be rejected by all who know how much easier colour is to modify than habit or structure, we are compelled to adopt the supposition, as being the most probable, that the coloration of the *Pleuronectidæ* is the result and not the cause of their form, and has, therefore, been acquired during the process of their flattening.

Although, however, we cannot, without gratuitous supposition, imagine that the unmodified ancestor of the group in question was coloured exactly like his progeny, there is still one other hypothesis by which atavism might be called in to explain such instances as that adduced by your correspondent. Whatever may have been the original cause of the flattening taking place, it is not likely that the initial variations (whether these were sudden and considerable, or gradual and slight), presented nearly so great a modification as that which we now observe. During these initial stages the partially modified individuals may have lain indifferently on either side, and so have acquired protective colouring on both. As the flattening, however, proceeded (from whatever cause), and the bones of the skull, etc., became more and more contorted, the new exigencies of the case might have caused the left side to be more and more used as a ventral surface, until its colouring, being of no further use, was allowed gradually to disappear. Upon this view the deviations from the normal colouring which now occur would be reversions, not to the bilaterally-symmetrical ancestors of the flat-fishes, but to their partially modified offspring. And, if this view were tenable, it might throw some light upon the otherwise inexplicable fact that some species of *Pleuronectidæ* are normally reversed—*i.e.* the left side instead of the right, constituting the upper surface—while in both kind of species individuals often occur which are reversed with reference to their specific type.

As however, this explanation is rather far-fetched, and, moreover, fails to account for the appearance of the partly white and the wholly white specimens above mentioned, it is best, I think, altogether to abandon the reversion theory.

Another, and, to my mind, a more probable one is open to us. Accepting the occurrence of abnormally reversed fish as an unexplained fact, we might, *à priori*, expect that a cross between a normal and a reversed individual of the same species might present the appearance described in your correspondent's letter—the abrupt, though sinuous line of demarcation between the two colours, which always attends the occurrence of this variation, being precisely analogous to that which obtains in higher animals when piebald. Moreover, the abnormal coloration being of most frequent occurrence in the Flounder and Plaice—fish which are also the most frequently reversed—and the occasional appearance of the entirely white and entirely brown varieties, are just the facts we should anticipate were this explanation the correct one. Of course it may be objected that abnormal colouring is not of nearly so frequent occurrence as abnormal reversal, but when we remember how utterly ignorant we are regarding the causes which determine reversal in the *Pleuronectidæ*, and the blending or non-blending of colours in all animals when crossed, we should not lay too much stress upon this objection.

The truth or falsehood of this explanation would admit of easy experimental test on the part of the Brighton Aquarium authorities. Should they, however, undertake such, they must not rest satisfied with mere simple crosses, however numerous, but also try various complex and reciprocal ones. The piebald fish they possess should also be crossed with several normal and reversed Plaice. Should all their experiments prove unsuccessful, they would still be interesting as tending to throw us back upon the only remaining explanation, viz. that all these instances of abnormal coloration are independent sports, and so affording us by far the most striking of the many examples in the animal kingdom of the tendency towards bilateral symmetry which abnormal colouring frequently presents.

Dunskaith, Ross-shire, May 15 GEORGE J. ROMANES

Venomous Caterpillars

THE concluding words of Mr. H. S. Wilson's letter in your last number only reiterate the truth of a fact. Nearly all British entomologists who have collected *Lepidoptera* must have had painful experience of the irritation caused by the hairs of some one or other of our Bombyces that have very hairy larvæ. *Porthesia chrysorrhœa* is the greatest delinquent in this respect; and some years since I suffered intense agony after collecting the pupæ of this species. The hairs of the caterpillar are woven into the cocoon and the web surrounding it, and I recommend anyone in search of a counter-irritant to rub his face and neck with his hands after collecting these pupæ. The result, although painful, will be edifying and admonitory. The hairs have no effect upon the harder skin of the palm of the hand and fingers; and I believe (with most entomologists) that their action is purely mechanical, *i.e.* they pierce the tender skin in multitudes. A precisely similar, though less severe, effect is caused by the hairs of some Boraginaceous plants, *e.g. Echium vulgare*. On the Continent the extreme irritation caused by the hairs of *Cnethocampa processionea* is well known; and the introduction of a brood of these larvæ into a drawing-room would probably be followed by effects similar to those caused by the king's "great flea" in Faust.

At present I consider that the existence of caterpillars actually venomous (*i.e.* with a poison-gland at the base of each hair) requires confirmation. There are some pachydermatous individuals upon whom the hairs of Bombyces have little or no effect. I am unhappily not one of those, but my mental hide repels the insidious attacks of romancers in Natural History.

Lewisham, May 16 ROBERT MCLACHLAN

BETWEEN the years 1857 and 1862 when stationed at Belozi, the capital of British Honduras, I made the acquaintance of a so-called venomous caterpillar, which was held in very great dread by the natives, who averred that "its *bite* always produced fever."

Knowing their superstitious habits, and that, as far as my knowledge of natural history went, there did not exist a caterpillar capable of producing a wound of any kind by *biting*, I resolved to test the truth of the assertion. Accordingly, and to the intense horror of the bystanders, I took one in my hand from a tree that was literally covered with them. It was about $1\frac{1}{2}$ in. long, by $\frac{3}{8}$ in. thick, of a blue-grey tint, and in addition to the fine long hairs which clothed it, was armed with clusters of short spines. These clusters were formed nto rows

and contained about a dozen spines each. After a careful examination, I came to the conclusion that they were most likely to be the seat of the venomous propensities attributed to the insect, so I struck the back of my right hand against them two or three times to see what would be the effect. They were very brittle, and broke off as they entered the skin. I thought no more about it till about an hour had elapsed, when I experienced in the wrist a dead pain which gradually extended to the arm-pit, followed by a swelling of the glands.

For the whole day the pain was sufficient to render my arm useless; hence I thought that there must be some poisonous secretion in the spines, for the irritation caused by fine points, even if barbed, would scarcely produce such an effect. The pain died away in the evening, unattended by any feverish symptoms whatever, for I was in excellent health at the time. Next day I examined several of the spines under the microscope; they were not barbed, but hollow, and under pressure emitted a colourless transparent fluid, to which I attributed the poisonous qualities which caused me so much pain. A. M. FESTING

The Demagnetisation of Needles.

IT may not be generally known that magnetised needles, like those used in galvanometers and telegraphs, are easily and rapidly demagnetised in the neighbourhood of other magnets, when the fields of the two magnets are not coincident—that is, when their respective lines of force are not in the same direction.

A striking instance of this has just been brought to my notice. A tangent galvanometer used for taking daily readings of the escape of the current to earth upon wires, when they are disconnected at their terminal points, was found constantly and gradually to be losing its delicacy. This was traced to be due to the demagnetisation of the needle. The needle was rehardened and even changed but with the same effect. The galvanometer was fixed near some Wheatstone's A B C instruments, which, being worked by magneto-electric currents, have powerful permanent magnets within them. The galvanometer was shifted to the other side of the office, when the effect entirely ceased.

Hence those who have delicate galvanometers should be careful to see that they are not kept in the field of permanent magnets, unless, as in the case of the mariner's compass, they are free to move in the direction of the lines of forces of the magnetic field in which they lie.

Microscopes—Information Wanted

I AM following up some investigations and experiments in which I require certain data, which, however, I cannot at present arrive at, not being in possession of sufficiently delicate and exact instrumental appliances. The information which I now desire to elicit from some more experienced observers than myself is of such importance as to be both useful and interesting to many of your readers, and I therefore crave your insertion of this communication. The information I require is all the more important as having a bearing upon many questions which are now attracting public attention, such as spontaneous generation, the initial stage and transitional forms of living organisms, also various researches in experimental physics, chemistry, &c. I desire to arrive at the following data:—

1. What is the estimated dimensions of most minute particles of matter which can be visible, under any circumstances or conditions, under the highest powers of the microscope? I leave out of consideration (under this head) the question whether such matter is living or dead, organic or inorganic, or in fact regardless of any of its properties whatever except its mere visibility as a minute portion of matter. Some observers speak of visible particles $\frac{1}{2000000}$th and $\frac{1}{3000000}$th of an inch diameter; this is surely near the limit.

2. What is the best or most accurate method of arriving at an estimate of the dimensions of such minute objects as are too small to admit of actual measurement by any of the appliances now in use? Every microscopist knows from experience that objects may be distinctly visible, not as a mere point, but having an appreciable diameter, and yet be too minute for actual measurement to any degree of accuracy.

3. Have the most recently constructed microscopic objectives, such as the $\frac{1}{50}$th or $\frac{1}{25}$th, any advantages over the $\frac{1}{16}$th or $\frac{1}{12}$th inch objectives in the determination of the data above referred to? and have immersion lenses any advantage in this respect? I find some difference of opinion on this point. Some microscopists consider that a really first-class $\frac{1}{16}$th with the use of deep eyepieces will enable us to see anything whatever which can be seen by any other objective of shorter focus. On the other hand, it is evident that a great number of the most experienced microscopists think otherwise; and from the very fact of their purchase of such expensive high powers, argue that such lenses are found to supply what other powers cannot accomplish.

It appears to me that there is too much of vague and indefinite assertion in regard to the comparative powers and qualities of microscopic objectives, and it is very desirable that some more definite results should be arrived at. With what precision and accuracy the results of astronomical observations are made! and taking into consideration that many of these results are obtained by different methods of observation, using different instruments, and by different observers, it is astonishing that the discrepancies and errors of observation are so small. It is generally admitted that the microscope is, to say the least, equally perfect, if not more so, than the telescope; and we should therefore expect a corresponding degree of accuracy in the results of microscopical observations. There are no doubt many who, like myself, have hitherto worked with only the medium and low powers, but wish to be possessed of the improved objectives of high power, but from want of sufficient information it is difficult to make a suitable choice. Arctic Exploration

THE story of the American Arctic Expedition under Mr. Hall is a wonderfully curious one; but are we justified, from what we have been told, in coming to the conclusion that the part of the crew of the *Polaris*, that has been rescued in so remarkable a manner, are "deserters?"

As far as I have understood the reports which have appeared in the papers, none of the rescued men have said they were deserters; and until we hear what those who remained on board the *Polaris* have to say, it appears to be unjust and reprehensible to bring so grave an accusation against men, possibly innocent.

Should it so happen that Mr. Tyson and his companions are deserters, can we put faith in the correctness of any part of their story?

There is certainly some mistake about the disposal of the six boats of the ship. As far as I can make out, only four, or at most five, are accounted for, namely, two abandoned in Smith Sound, and the two on the ice with Mr. Tyson, one of which was burnt for fuel, and the other, that in which they were when rescued, and which was taken on board the *Tigris*.

The Westerly Progress of Cities

IN his work on the Atmosphere, M. Flammarion draws attention to a peculiarity in the habits of our large towns which everyone must have noticed. "The wealthy classes have a pronounced tendency to emigrate westward, leaving the eastern districts for the labouring populations. This remark applies not only to Paris, but to most great cities—London, Vienna, Berlin, St. Petersburg, Turin, Liége, Toulouse, Montpellier, Caen, and even Pompeii."

Having frequently remarked this "westing" in many English towns, I have lately written to several friends, asking for definite information on this point, concerning the town in which they are resident. With scarcely an exception the reply of each showed, to alter Bishop Berkeley's line a little, that:—"Westward the course of fashion takes its way." This is true, I believe, of Edinburgh, Dublin in former years at any rate, Glasgow, Liverpool, and Manchester, to some extent, Birmingham, Leeds, Southamptom, and Bristol. No doubt many of your readers can very largely extend this list; it would be interesting to collect wide information on this question. For supposing it established as a general fact, what an excellent speculation to buy up land in the west of a rapidly growing town like Leicester or Bradford? I am ignorant of these things; perhaps it is common to do so already.

Whence arises this tendency? It can hardly be an accident, nor can it be due to the direction of the river beside which the town may happen to be built, for in the towns named, many o

the streams, where they exist, run in different directions. M. Flammarion thinks the westward movement is caused by the direction of sunset, towards which people feel disposed to form their gardens, build their houses, and in that direction most inclined to walk; the evening and not the morning being their usual time of recreation. Is not a more probable explanation to be found in the general dislike of an easterly wind? And, moreover, it has been pointed out that a westerly wind usually causes the greatest fall in the barometer, and thus the eastern portion of a town becomes inundated with the effluvia which arises on such occasions. Another and perhaps more potent cause may be the prevalence in Europe of south-westerly winds during the greater part of the year, whereby the smoke and vitiated air of a town is carried to the north-east more frequently than elsewhere; so that it is notorious the west end of a city is freer from smoke than the east end. Possibly all these causes may combine to produce this curious occidental march of the fashionable quarter. W. F. BARRETT

Isleworth, May 5

Etymology of Aphis

WITH regard to the etymology of Aphis, I find the following in Lennis' "Synopsis der Natur-geschichte des Thier-reichs," p. 578:—

"Aphis, Blattlaus, nach Fabricius von ἀφίστημι trennen, abstehen; richtiger vielleicht ἄφυσσα von ἀφύω schöpfen; musste dann aber Aphys heissen."

The second explanation is ingenious; but neither seems to my mind satisfactory. W. W. SPICER

Itchen Abbas Rectory, Alresford, May 14

Phosphorescence in Wood

ONE wet evening last autumn some pieces of phosphorescent wood were brought to me, which had formed part of a dead beech-tree that had been cut down during the day. They shone brightly that evening. The next night they were dark until dipped in water, when the light revived but was much fainter than before. On the third night they seemed to have lost the phosphorescence entirely, for water produced no visible effect on them.

Your correspondent, Mr. W. G. Smith, states that the luminosity of decaying wood is due to the presence of various kinds of fungus, but does not say what is the cause of it either in fungi or glow-worms. There is something so striking in the light unaccompanied by sensible heat, that an unlearned person's curiosity is roused to know whether phosphorescence is akin to burning or not. Where can one learn what is known about it? C. A. M.

Tears and Care of Monkeys for their Dead

WE have heard much of late about the emotions of animals, and might have heard it sooner had Charles Bell's profound work on the "Anatomy and Expression," received due attention. The moral or psychical emotions of the brutes most resembling man in structure are peculiarly interesting, and sufficient observations as to this point on the monkeys seem to be yet wanting. Before I saw a picture of a weeping monkey, by Edwin Landseer, I always thought that this animal could be moved neither to tears nor laughter; and I still think that more observations, by persons most familiar with monkeys, are required on this subject, and hope to elicit them by this note in NATURE. But an affectionate care of brutes for their dead has been considered either very rare or inexistent, though it would seem to have been shown by monkeys. At least, we have evidence to this effect in the "Oriental Memoirs," 4 vols. 4to, London, 1813, by James Forbes, F.R.S., and indeed, very likely, there may be still better observations, with which I am unacquainted, on the subject. Here is an extract thereon from Mr. Forbes's book:—

"One of a shooting party, under a banian tree, killed a female monkey and carried it to his tent, which was soon surrounded by forty or fifty of the tribe, who made a great noise and seemed disposed to attack their aggressor. They retreated when he presented his fowling-piece, the dreadful effect of which they had witnessed and appeared perfectly to understand. The head of the troop, however, stood his ground, chattering furiously; the sportsman, who perhaps felt some little degree of compunction for having killed one of the family, did not like to fire at the creature, and nothing short of firing would suffice to drive him off. At length he came to the door of the tent, and finding threats of no avail, began a lamentable moaning, and by the most expressive gesture seemed to beg for the dead body. It was given him; he took it sorrowfully in his arms, and bore it away to his expecting companions: they who were witnesses of this extraordinary scene, resolved never again to fire at one of the monkey race." GEORGE GULLIVER

Canterbury, May 24

RECENT WORKS ON ECHINODERMS

AMONG the most important of recent works on Echinoderms may be mentioned "The Revision of the Echini," by Alex. Agassiz. Of this work, which will be completed in four parts, Parts 1 and 2 were published early in this year, Part 3 is going through the press and may possibly be published in August next; it will contain the description of species not included in Part 2. Part 4 may be published this year; it will contain a review of the anatomy and classification of the order. This part will not be so well illustrated as the author had intended, for six plates of anatomy, the results of many years' labour, with all Mr. Agassiz's drawings, were lost in the great conflagration of November 9, and it will be impossible to supply their places. The present parts are accompanied by an atlas of forty-nine plates. Part 1 contains, in addition to an introductory chapter, the bibliography of the subject, a chapter on Nomenclature, a Chronological List of Names used from 1554, a Synonymic Index, and a chapter on Geographical Distribution. Part 2 contains Description of the Echini of the Eastern Coast of the United States, together with a report on the deep sea Echini collected in the Straits of Florida, by Count Pourtalès, Assistant United States' Coast Survey in the years 1867—1869.

The synonymic index will be simply invaluable to the investigator of the Echini. He who investigates the life-history of a species must surely know the name of the species he is investigating. It is therefore, even from this point of view, by no means an unimportant task to unravel the complicated and tangled network of synonyms; themselves an evidence of lack of knowledge on the part of many. Agassiz regards—and very correctly so—synonomy as the *History of the Species*, not its natural history. His opportunities for examining the types of those authors who have written on the subject were immense, and he has thoroughly availed himself of them. The great Museums of London, Paris, Copenhagen, Vienna, Stockholm, and elsewhere, were all visited by Agassiz; while the original specimens described by Klein, Gray, Desor, Michelin, and others were most carefully examined, and it must not be forgotten that in addition the Harvard College Museum contains one of the most perfect collections of Echini in the world.

It would serve no useful purpose if in this place we examined in any detail the catalogue of species of Echini given on pp. 88, 203 of this memoir; for convenience of reference the genera and the species in their respective genera are arranged alphabetically, but there is added a list of all known species arranged in their natural order, with the name adopted by Agassiz, the original name and the principal localities.

In treating of the geographical distribution of the Echini, Agassiz remarks that it was a matter of great surprise to him to find how few species, hitherto not noticed, were to be found in the European collections. Everywhere, although from different localities, were found repetitions of species already well known—so that in making a map of the littoral regions, but short stretches of shore were left out as unexplored. Though therefore new species may and will undoubtedly turn up, even in

well explored localities, we probably have even now a very fair representation of the littoral Echini of the world. It would of course be rash to make any predictions as to the number of new forms that will doubtless be brought to light by the researches of Wyville Thomson—but these will probably be deep-sea forms. Did space allow we would gladly have dwelt longer on this most interesting portion of Agassiz's memoir.

The total number of genera adopted is 90, with 207 species. The atlas accompanying these parts contains 49 plates—the first seven are devoted to charts, representing the distribution of the Echini throughout the old and new worlds, and the remaining portion to figures of some of the new or little known species. Some of the plates are photographs—and very excellent ones – others are photo-printed by the albert type process, and while these have scarcely the brilliancy or evenness of detail as such engravings as those of Echini in the expedition to Egypt, yet when the enormous difference in cost is taken into account, these photo-printed plates must be a subject of congratulation to the working and not over-rich naturalist. Some others of the plates are lithographed from Agassiz's drawings, and these we would select as being the most useful in this atlas.

Next we would mention a very important paper by Prof. Lovén, published in "Öfversigt af Kongl. Vetenskaps-Akademiens Förhandlingar," 1871, No. 8. This paper was read on June 14, 1871, but was not, we think, published until the summer of 1872, and as a translation of it in full by Mr. Dallas has been published in the "Annals and Magazine of Natural History," vol. x., 4th series, October to December 1872, we will but very briefly allude to it here. Prof. Lovén describes some very small spheroidal button-like bodies furnished with a short stalk, which is normally attached to a small, slightly projecting tubercle, which he calls *Spheridia*; these occur apparently in all Echinoidea except *Cidaris*; they are fully described as they occur in the different families. Lovén next describes the order which prevails in the disposition of the ambulacral plates throughout the whole class, for which he even gives a formula.

Passing from the sea urchins to the Brittle stars, we have also, from the Proceedings of the Royal Academy of Stockholm, a paper by Ljungman describing the collection of Ophiuroids made by Dr. Goës in the West Indies, in the Josephine Expedition. Fifty-seven species are enumerated, of which fifteen are described as new. Many of these latter were dredged from very considerable depths. The author adds to his paper a conspectus of the genera of Ophiodermatidæ and a conspectus of the Atlantic species of the genera *Amphiura* and *Amphipholis*.

Lütken, in an important memoir published in the Proceedings of the Royal Academy of Copenhagen, Part 2, 1872, entitled "Ophiuridarum novarum vel minus cognitarum descriptiones nonnullæ," describes a number of new species from different parts of the world, as well as gives some details of little known species. To this memoir there is appended a chapter "On Spontaneous Division in the Star Fishes," at the conclusion of which the author sums up with the following general propositions:—(1), The most energetic manifestations of the faculty of regeneration in animals is the power of divisibility; (2), In certain forms of Radiates, in which the faculty of regeneration is very highly developed, spontaneous division takes place alone, as in Ophiuroids and Asteroids, or together with gemmation, as in Actinia; (3), Actual spontaneous division or "Schizogony," in the Actinia, Medusa, Asteroids, and Ophiuroids (which must not be confounded with the disguised forms of gemmation met with in Infusoria and certain Chetopods) may be regarded as a peculiar form of Agamic reproduction such as Blastogony, Sporogony, and Parthenogony.

Lastly we have to mention the appearance of a modest catalogue of Echinodermata of New Zealand, with diagnosis of the species, by Capt. F. W. Hutton, F.G.S., Assistant Geologist, Colonial Department. In it thirty-four species are described, eighteen of them being described as probably new to science.

E. PERCEVAL WRIGHT

ON THE SPECTROSCOPE AND ITS APPLICATIONS

X.

I HAVE not yet done with the spot-spectrum referred to in last article. Not only is there general absorption, but there are indications of increased selective absorption in the case of the line D, as I could also show if I were dealing with the iron lines, the magnesium lines, or the other well-known lines of the solar spectrum. Not only, then, have we a general absorption, increasing as the middle of the sunspot is approached, but this sodium line D is also thickened, so that we have, as a result of a single examination of a single sunspot, the fact that a sunspot is due to general absorption, *plus* special absorption in some particular lines.

Now, in what I said some time since on the radiation of hydrogen, I pointed out to you that the F line of hydrogen was different from the C line—in fact, I showed that it widened out towards the sun—and I also told you that Dr. Frankland and myself have asserted that that widening out is due to pressure, and we have been able artificially to widen out this F line of hydrogen by increasing the pressure. Now it struck us that possibly we might find some connection between that widening out of the F line of hydrogen and the widening out of the sodium line in the spot which I have just shown you. There is an experiment by which it is perfectly easy for us to reproduce this artificially, so that you see we can begin at the very outside of the sun by means of hydrogen, and see the widening of the hydrogen lines as the sun is approached; and then we can take the very sun itself to pieces, and, by examining the pieces, see that the sodium lines vary in thickness in different parts of the spot, as the hydrogen does outside the spot region altogether: in fact, the pressure is continually increasing down in the spot exactly in the same way as it increases in the hydrogen envelope towards the sun.

If we take a tube containing some metallic sodium sealed up in hydrogen, and pass a beam of light from the electric lamp through it, by decomposing this beam with our prisms we shall obtain an ordinary continuous spectrum without either bright or dark lines, but by heating the metallic sodium in the tube which is placed in front of the slit, we really fill that tube with the vapour of sodium; and as the heating will be slow, the sodium vapour will rise very gently from the metal at the bottom, so that we shall get layers of different densities of sodium vapour filling the tube. Immediately the sodium begins to rise in vapour, a black absorption line shows itself in our spectrum in precisely the same position as the yellow line of sodium, and you will find that the thickness of the sodium absorption line will vary with the density of the stratum of vapour through which the light passes. Thus from the upper part of the tube we obtain a fine delicate line, which gradually thickens as we approach the bottom; and thus we reproduce the appearance in the spectrum of the spot where the layers of sodium vapour are very dense, and the very fine delicate line of the sodium vapour when thrown up into the sun's chromosphere.

We must next speak of what happens in the case of the magnesium lines. A very obvious magnesium line is lettered *b* in the solar spectrum. It is a triple line, separated by different intervals. There is a very impor-

tant fact connected with these lines, which appear when magnesium vapour is thrown up into the envelope which I have called the Chromosphere. By means of the new method of research, it is quite possible to see, as I explained to you on a former occasion, what passes, which the eye could not possibly see. For instance, it is quite possible, by means of the spectroscope, to detect the existence of magnesium vapour outside the sun, although you know that, except during eclipses, we are never able to see these vapours. What I wish to call your attention to in the present case is this. We have there the three magnesium lines, and two of them are much thicker than the remaining one: and these two lines travel very much higher into the outside region than does the third one. Now, you will see in a moment that that indicates to us a fact something like this,—that the spectrum of magnesium, such as is generally at work, which cuts out these very black absorption lines in the solar spectrum, while the sodium gives us the yellow line D, is really a thing which is competent to give us three lines. This vapour, I say, is a thing, generally speaking, competent to give us three lines in this position; but if it so happens that when the magnesium is thrown up to a particular height we simply get two lines, the third stopping short, I think you will see that there is some force in one's reasoning, when one suggests that possibly in those regions where we find the hydrogen F line thin instead of thick, as I have shown it to you, and where the magnesium lines become reduced to two instead of three, the spectrum of magnesium vapour, like the spectrum of hydrogen, becomes very much more simple by *the reduction of pressure*, and therefore, that we should be able artificially, as in the case of hydrogen, and as in the case of sodium, to reproduce this result. In fact, it is perfectly easy to reproduce it, for we find by reducing the pressure of magnesium vapour we really can reduce that triple line of magnesium to a double one; so that, you see, we have three distinct lines of research, all leading us to the fact that where Kirchhoff placed an immensely dense atmosphere around a liquid sun, we really have vapour of considerable tenuity, by no means so dense as he supposed.

There is another point of very great interest which I should bring before you.

Mr. Huggins, who has done so much in his researches on stars, told us some few years ago that the spectrum of that wonderful variable star τ Coronæ, which had been just discovered, indicated that, over and above the light which we got from the star generally, we get evidence of incandescent hydrogen in the spectrum, so that the spectrum was a thing such as had never been seen before; for we got, in addition to the ordinary evidence of absorption visible in the spectrum of a star, as in the spectrum of the sun, indications also of selective radiation. There are indications of bright lines superposed above the others. Now, let me tell you—and this is a very important part of the question—that by observing the various changes that take place in our central luminary, it is quite possible to see on the sun almost any day evidence of its being violently agitated; that there are certain regions of the sun which appear exactly as that variable star did—that is to say, in addition to the ordinary absorption lines visible in the solar spectrum, the spectrum of these regions indicates to us that the hydrogen, instead of being black, instead of reversing the spectrum, as you have seen it in these spectra that I have shown you, really is bright, or else the hydrogen lines cease to be visible altogether, as in α Orionis.

I have to give you, as the last application of spectrum analysis, the power which the prism gives us of investigating, so to speak, the meteorology of the sun, the velocity with which the different stars are moving through space, and the velocity with which the storms are travelling over the face of the central luminary. Many of you know, no doubt, that Mr. Huggins, in his observations of the spectrum of the star Sirius, saw that the hydrogen lines were much developed; and in a further examination, carried on by the method in which the spectrum of hydrogen and other vapours which he wished to examine were absolutely visible in the field of view at the same time as was the spectrum of the star, Mr. Huggins was astonished to find that the hydrogen lines no longer occupied their usual positions, but that they were all jerked, so to speak, a little to the side of the place which they occupied in the spectrum of the hydrogen which he rendered incandescent in his tubes. The F line of hydrogen which he observed in the spectrum of Sirius he found did not exactly occupy the same position in the spectrum as did the actual F line of hydrogen, the incandescent hydrogen with which he compared it (Fig. 53). Owing to a physical law, which I have not time to explain to you now, it is perfectly easy, by means of the prism, to determine the velocity with which the light-source is moving to or from us; and therefore, if this holds good for absorption, we could determine the velocity with which any absorbing medium is rushing to or receding from us. In the case of Sirius, for instance, Mr. Huggins determined that the velocity of the star in a direction from the eye, the measure of recession, was something like twenty miles a second. I am sorry I have not time to fully explain this very beautiful adaptation of the spectroscope, but I may say that the position of a line, bright or dark, in the spectrum depends upon its wave-length—that is to say, the length of the wave of light which produces that colour. Thus, the length of a wave of red light is about $\frac{1}{39000}$ of an inch, and that of a wave of violet light is about $\frac{1}{57500}$ of an inch. I think when I mention that, you will see at once the possibility of determining any alteration of velocity—for an alteration of wave velocity we have, or appear to have, whether we move towards an object, or whether an object moves towards us, just in the same way as in the case of sound, and in the case of a wave reaching the shore. Suppose yourself a swimmer carried on a wave; if you are going with the wave it seems long, but if you attempt to swim against it it seems short. So with all these waves, beating from all these orbs peopling the depths of space on to the earth. If by the motion of those bodies or by our own motion, the waves are crushed together, we get an alteration in the light, which the prism alone is able to determine. If the luminous object is approaching the eye rapidly, the vibrations causing light will, of course, fall on the eye more frequently in the same time than if the bodies were at rest—or, in other words, the waves will be shortened; then the position of the dark or bright lines, as the case may be, will be shifted in the direction of the most refrangible rays—that is to say, towards the violet; whilst if the bodies are separating, the shifting will take place in the direction of the red or least refrangible rays. In the case of Sirius, the star was receding from us, and we got longer waves, and the lines are nearer the red end of the spectrum to such an extent as to leave unaccounted for a motion of recession from our sun amounting to something between 18 and 22 miles per second. Other stars, such as Betelgeux, Rigel, Castor, Regulus, and many of the stars in Ursa Major, are found to be moving away from the sun. Some, however, move rapidly towards us. Arcturus approaches us with a velocity of 55 miles per second; Vega and α Cygni, Pollux and α Ursa Majoris, also approach the sun with a velocity varying from 40 to 60 miles per second. If now we take a spot-spectrum (Fig. 54), in which, instead of the sodium line D, we have the F line of hydrogen, this strange crookedness which you notice is really a crookedness due to the fact that in one place we have incandescent hydrogen rising up with tremendous velocity, and in another we have it rushing down cool with tremendous velocity; again, we

have hydrogen in a different condition altogether. We know that in this case we have a variation of velocity, because we get distinct changes in one direction or the other, and we get changes in both directions. We can determine by the amount of crookedness of the hydrogen, whether bright or dark, how far it is driven from its normal condition, and then how fast per second the hydrogen is travelling. In one case the velocity was something like 38 miles a second; in other words, we had heated hydrogen coming up at the rate of something

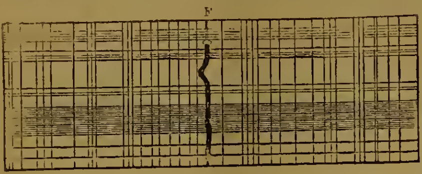

FIG. 54.—Deviation of the F line in a spot-spectrum.

like 38 miles a second, and cool hydrogen rushing down at something like an equivalent rate. Now, we are not only enabled, by a practical application of the prism, to determine these up and down rushes on the sun, by which we are enabled to learn much of its physical constitution, but also the rate at which storms travel over the sun—what we should call winds. The way that has been done will be perfectly clear on an inspection of the engraving (Fig. 55). It may appear strange to you that we should be able to observe a cyclone on the sun, but I hope to be able to prove to you that this is really a cyclone. Here is a spectrum of the region of the sun near the limb, and here is the hydrogen line. It is clear, if what I have said is true, that the incandescent hydrogen is there receding from us because the line inclines to the red. It is evident also, that in this case, when we get the line widened out towards the violet, it is coming towards us; therefore we have the thing travelling in both directions. It is obvious to you, I think, that if the slit enabled us to take in the whole cyclone, we should get an indication of motion in two directions; we should have the line diverted both towards the violet part of the spectrum, in the case of the hydrogen rushing towards us,

FIG. 55.—Shifting of the F line in a solar cyclone.

and towards the red in the case of the hydrogen rushing away from us in this circular storm, and the extreme velocity will be determined by the extreme limit to which the hydrogen line extends. In this case, the storm was moving with a velocity of something like 100 miles a second, which, I dare say, strikes you as something terrible; but if you compare the size of the sun with that of the earth, I think you will see it was nothing very wonderful after all.

In further evidence of the truth of this, the last application of the spectroscope, I will show you two pictures of solar prominences 27,000 miles high, drawn at an interval of ten minutes. Here you see, first, the prominence as it appeared at a particular time on a particular day in March 1869 (Fig. 56). I wish to call your attention to the left-hand portion of the prominence, which you see is pretty straight. In ten minutes afterwards the whole thing

FIG. 56.—Prominence observed March 14, 1869, 11h. 5m.

changed, and, as you see by the next picture (Fig. 57), the nearly straight portion is quite gone. That will give you some idea of the indications which the spectroscope reveals to us of the enormous forces at work in the sun, merely as representing the stars, for everything we have to say about the sun, the prism tells us—and it was the first to tell us—we must assume to be said about the stars. I have little doubt that, as time rolls on, the spectroscope

FIG. 57.—The same prominence, 11h. 15m.

will become, in fact, almost the pocket companion of every one amongst us; and it is utterly impossible to foresee what depths of space will not in time be gauged and completely investigated by this new method of research.

J. NORMAN LOCKYER

ON THE ORIGIN AND METAMORPHOSES OF INSECTS *

V.

THE development of the beautiful *Comatula rosacea* (Fig. 41) has been described in the "Philosophical Transactions," by Prof. Wyville Thomson.* The larva quits

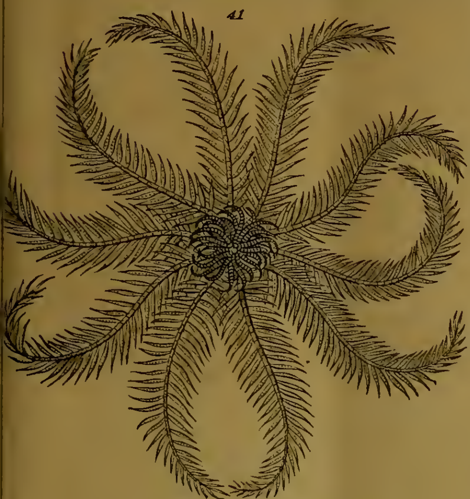

Fig. 41.—Comatula rosacea (after Forbes).

the egg, as shown in Fig. 42, in the form of an oval body about $\frac{1}{30}$ inch in length, something like a small barrel, surrounded by four bands or hoops of long vibratile hairs or ciliæ. There is also a still longer tuft of hairs at the narrower posterior end of the body. Gradually a number of minute calcareous spines and plates make their appearance (Fig. 43) in the body of this larva, and at length

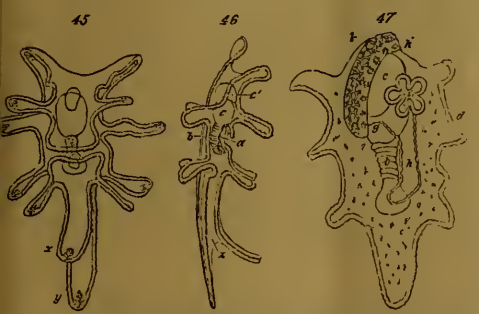

Fig. 45.—Larva of Starfish (Bipinnaria), × 100 (after Muller). 46, Larva of Starfish (Bipinnaria), × 100, seen from the side. *a*, mouth; *b*, œsophagus: *c*, stomach; c^1, intestine. 47, Larva of another Bipinnaria, showing the commencement of the starfish. *g*, canal of the ciliated sac; *i*, rudiments of tentacles; *d*, ciliated band.

arrange themselves in a definite order, so as to form a bent calcareous club or rod with an enlarged head.

As this process continues the little creature gradually loses its power of swimming and sinks to the bottom, loses the bands and cilia and attaches itself to some stone or other solid substance, by its base, the knob of the club being free. The calcareous framework increases in size, and the expanded head forms itself into a cup, round which from five to fifteen delicate tentacles, as shown in Fig. 44, make their appearance.

In this stage the young animal resembles the Crinoids, a family of Echinoderms which were very abundant in earlier geological periods, but which have now almost disappeared, being, as we see, represented by the young states of our existing, more advanced, species. This attached, plant-like condition of Comatula, was indeed at

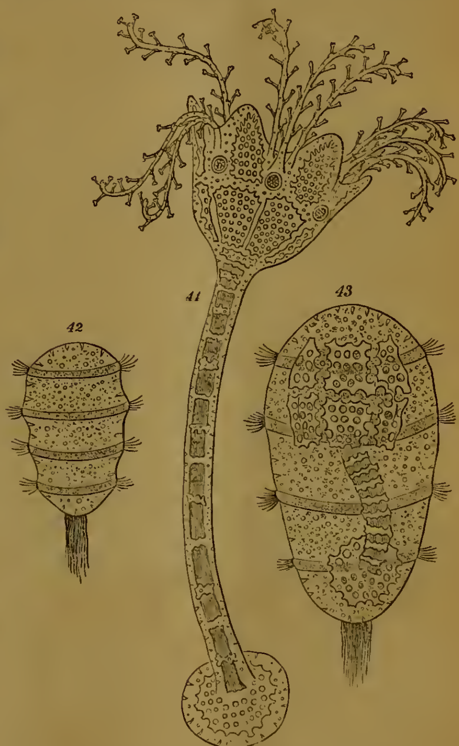

Fig. 42.—Larva of Comatula rosacea (after Thomson). 43, Larva of Comatula rosacea, more advanced. 44, Larva of Comatula rosacea, in the Pentacrinus state.

first supposed to be a Crinoid, and was named Pentacrinus, though we now know that it is only a stage in the development of Comatula. The so-called Pentacrinus increases considerably in size, and after various gradual changes, which time does not now permit me to describe, quits the stalk, and becomes a free Comatula.

The metamorphoses of the true star-fishes are also very remarkable. Sars discovered in the year 1835 a curious little creature about an inch in length, which he named *Bipinnaria asterigera*, and which he then supposed to be allied to the ciliograde Medusæ; subsequent observations however, made in 1844, suggested to him that it was the

* Continued from p. 70.
† Philosophical Transactions, 1865, vol. clv. . 513.

larva of a star-fish, and in 1847 MM. Koren and Danielson satisfied themselves that this was the case.

Figs. 45 and 46 represent the front and side view of a Bipinnaria found by Muller* near Marseilles. *a* is the mouth, *b* the œsophagus, *c* the stomach, *c′* the intestine. Fig. 47 represents a somewhat older specimen in which the Starfish (*k*) is already beginning to make its appearance.

But while certain Starfishes thus go through metamorphoses, similar in character to, and not less remarkable than, those of sea-eggs; there are others, as, for instance, the genus Asteracanthium, in which the organs and appendages special to the Pseudembryo, are in abeyance, while in Pteraster "the zooid is reduced to an investing sheet of sarcode." †

Even in the same species the degree of development attained by the larva differs to a certain extent according to the state of the temperature, the supply of food, &c. Thus in Comatula, specimens which are liberally supplied with sea-water, and kept in a warm temperature, hurry as it were through their early stages, and the free larva becomes distorted by the growing Pentacrinus, almost before it has attained its perfect form. On the other hand under less favourable conditions, if the temperature is low, and food less abundant, the early stages are prolonged, the larva is longer lived, and reaches a much higher degree of independent development. Weissmann has observed similar differences in the larvæ of Flies,‡ and it is obvious that these facts throw much light on the nature and origin of metamorphoses as we see them among insects, but the latter question we shall now proceed to consider.

On the Origin of Metamorphoses

The question still remains, Why do insects pass through metamorphoses? Messrs. Kirby and Spence tell us they "can only answer that such is the will of the Creator;"§ which, however, is rather a general confession of faith than an explanation of metamorphoses. And this they appear to have felt themselves; for they immediately proceed to make a further suggestion. "Yet one reason," they say, "for this conformation may be hazarded. A very important part assigned to insects in the economy of nature, as I shall hereafter show, is that of speedily removing superabundant and decaying animal and vegetable matter. For such agents an insatiable voracity is an indispensable qualification, and not less so unusual powers of multiplication. But these faculties are in a great degree incompatible; an insect occupied in the work of reproduction could not continue its voracious feeding. Its life, therefore, after leaving the egg, is divided into three stages."

But there are some insects, as, for instance, the Aphides, which certainly are not among the least voracious, and which grow and breed at the same time. There are also many scavengers among other groups of animals, such, for instance, as the dog, the pig, and the vulture, which undergo no metamorphosis.

It is certainly true that, as a general rule, growth and reproduction do not occur together; and it follows, almost as a necessary consequence, that in such cases the first must precede the second. But this has no immediate connection with the occurrence of metamorphoses. The question is, not why an insect does not generally begin to breed until it has ceased to grow, but why, in attaining to its perfect form, it passes through such remarkable changes. And in addition to this, we must consider, first, the sudden and apparently violent nature of these transitions, and, secondly, the immobility of the animal in its pupa state; for undoubtedly the quiescent and deathlike condition of the pupa is one of the most remarkable characteristics of insect-metamorphosis.

* l c Zweit. Abh. Pl. 1, Figs 8 and 9.
† Thomson, on the Embryology of the Echinodermata, *Natural History Review*, 1863, p 415.
‡ Zeits. fur Wiss. Zool, 1864, p 228.
§ Introduction to Etymology, 6th Ed. i. p. 61.

In the first place, it must be observed that many species which differ considerably in their mature state, agree more nearly when young. Thus birds of the same genus, or of closely allied genera, which, when mature, differ much in colour, are often very similar when young. The young of the lion and the puma are often striped, and fœtal whales have teeth. Leidy has shown that the milk teeth of the genus *Equus* resemble the permanent teeth of the ancient *Anchitherium*, while the milk-teeth of *Anchitherium* again approximate to the dental system of the still earlier *Merychippus*. Rutimeyer, while calling attention to this interesting observation, adds that the milk-teeth of *Equus caballus* in the same way, and still more those of *E. fossilis*, resemble the permanent teeth of *Hipparion*.

In fact, the great majority of animals do go through well-marked metamorphoses, though in many cases they are passed through within the egg, and thus do not come within the popular ken. "La larve," says Quatrefages, "n'est qu'un embryon à vie independante."* Those naturalists who accept in any form the theory of evolution, consider that "the embryonal state of each species reproduces more or less completely the form and structure of their less modified progenitors."† "Each organism," says Herbert Spencer,‡ "exhibits within a short space of time a series of changes which, when supposed to occupy a period indefinitely great, and to go on in various ways instead of one way, give us a tolerably clear conception of organic evolution in general.

The naturalists of the older school do not, as Darwin and Fritz Muller have already pointed out, deny the facts, though they explain them in a different manner—generally by the existence of a supposed tendency to diverge from an original type. Thus Johannes Muller says "the idea of development is not that of mere increase of size, but that of progress from what is not yet distinguished, but which potentially contains the distinction in itself, to the actually distinct,—it is clear that the less an organ is developed, so much the more does it approach the type, and that, during its development, it more and more acquires peculiarities. The types discovered by comparative anatomy and developmental history must therefore agree."

And again, "What is true in this idea is, that every embryo at first bears only the type of its section, from which the type of the class, order, &c., is only afterwards developed."

Agassiz also observes that "the embryos of different animals resemble each other the more the younger they are." There are, no doubt, cases in which the earlier states are rapidly passed through, or but obscurely indicated; yet we may almost state it as a general proposition, that, whether before or after birth, animals undergo metamorphoses. The maturity of the young animal at birth varies immensely. The kangaroo (*Macropus major*), which attains a height of seven feet, ten inches, does not when born exceed one inch and two lines in length; the chick leaves the egg in a much more advanced condition than the thrush; and so among insects the young cricket is much more advanced, when it leaves the egg, than the fly or the bee; and it is a familiar fact, that in this respect, though not of course to anything like the same extent, differences occur even within the limit of one species.

In oviparous animals the condition of the young at birth depends much on the size of the egg; where the egg is large, the abundant supply of nourishment enables the embryo to attain a higher stage of development; where the egg is small, and the yolk consequently scanty, it is soon exhausted, and the embryo requires an addi-

* Metamorphoses de l'Homme et des Animaux, p. 133.
† Darwin, Origin of Species, 4th Ed. p. 532.
‡ Principles of Biology, vi. p. 349.

tional supply of food. In the former case the embryo is more likely to survive; but, on the other hand, when the eggs are large, they cannot be numerous, and a multiplicity of germs is, in some circumstances, a great advantage. Even in the same species the development of the egg offers certain differences.*

The metamorphoses of insects depend then primarily on the fact that they quit the egg in a very early condition; many--as, for instance, flies and bees—before the thoracic segments are differentiated; others—as locusts, dragon flies, &c., after the formation of the legs, but before that of the wings.

We may now pass to the second part of the subject, that is to say, the sudden and abrupt instance of the changes which insects undergo. The development of an Orthopterous insect, indeed—say, for instance, of a grasshopper—from birth to maturity is so gradual, that but for the influence on our nomenclature exercised by the most striking changes which occur in insects of the Heteromorphous series, they would perhaps never have been classed as metamorphoses. But though the changes from the caterpillar to the chrysalis, as from the chrysalis to the butterfly, are apparently sudden and abrupt, this is in reality more apparent than real; the changes in the internal organs, though rapid, are in reality gradual; and even as regards the external form, though the metamorphosis may take only a few moments, this is but the change of outer skin—the drawing away, as it were, of the curtain; and the new form which then appears has been in preparation for days or, perhaps, weeks before.

Swammerdam, indeed, supposed (and his view was adopted by Kirby and Spence) that the larva contained within itself "the germ of the future butterfly, enclosed in what will be the case of the pupa, which is itself included in three or more skins, one over the other, that will successively cover the larva." This is a mistake; but it is true that, if a larva is examined shortly before it is full grown, the future pupa may be traced within it. In the same manner, if we examine a pupa which is about to disclose the butterfly, we find the future insect, soft indeed and imperfect, but still easily recognisable, lying more or less loosely within the pupa-skin.

One important difference between an insect and a vertebrate animal is, that whereas in the latter, as for instance in ourselves, the muscles are attached to an internal bony skeleton, in insects no such skeleton exists. They have no bones, and their muscles are attached to the skin. Hence the necessity for the hard and horny dermal investment of insects, so different from the softness and suppleness of our own skin. Moreover the result is, that without a change of skin a change of form is impossible. The chitine, or horny substance, forming the outside of an insect, is formed by a layer of cells lying beneath it, and, once secreted, cannot be altered. From this it follows that every change of form is necessarily accompanied by a change of skin. In some cases, as for instance in *Chloëon*, each change of skin is accompanied by a change of form, and thus the perfect insect is more or less gradually evolved. In others, as for instance in caterpillars, several changes of skin take place without any material alteration of form, and the change, instead of being spread over many, is confined to the last two moults.

The explanation of this difference is, I believe, to be found in the structure of the mouth. That of the caterpillar is provided with a pair of strong jaws, fitted to eat leaves; and the digestive organs are adapted for this kind of food. On the contrary, the mouth of the butterfly is suctorial; it has a long proboscis, beautifully adapted to suck the nectar from flowers, but which would be quite useless, and indeed only an embarrassment to the larva. The digestive organs also are adapted for the assimilation, not of leaves, but of honey. Now it is evident that if the mouth-parts of the larva were slowly metamorphosed into those of the perfect insect, through a number of small changes, the insect would in the meantime be unable to feed, and liable to perish of starvation in the midst of plenty. On the contrary, in the Orthoptera, and as a general rule, among those insects in which the changes are gradual, the mouth of the so-called larva resembles that of the perfect insect, and the principal difference is in the presence of wings.

Similar considerations throw much light on the nature of the chrysalis or pupa state—that remarkable period of death-like quiescence which is one of the most striking characteristics of insect metamorphosis. The comparative quiescence of the pupa is mainly owing to the rapidity of the changes going on in it. In the chrysalis of a butterfly, for instance, not only (as has been already mentioned) are the mouth and digestive organs undergoing change, but the same is the case with the muscles. The powerful ones which move the wings are in process of formation; and even if they were in a condition favourable to motion, still the nervous system, by which the movements are set on foot and regulated, is also in a state of such rapid change that it could scarcely act.

It must not be forgotten that all insects, indeed all articulate animals, are inactive for a longer or shorter space of time after each moult.

The slighter the change the shorter the period of inaction. Thus, after the ordinary moult of a caterpillar, the insect only requires rest until the new skin is hardened. When, however, the change is great and gradual, the period of inaction is correspondingly prolonged. The inactivity of the pupa is therefore not a new condition peculiar to this stage, but a prolongation of the inaction which accompanies every change of skin. Most pupæ indeed have some slight powers of motion; those which assume the chrysalis state in wood or under ground usually come to the surface when about to assume the perfect state, and the aquatic pupæ of certain Diptera, swim about with much activity. Among the Neuroptera certain families have pupæ as quiescent as those of the Lepidoptera; others, as, for instance, Raphidia, are quiescent at first, but at length acquire sufficient strength to walk, though enclosed within the pupa skin, a power dependent partly on the fact that this skin is very thin. Others again, as, for instance, dragon-flies, are quiescent on assuming the pupa state, only in the same manner and for a similar time as at other changes of skin.

JOHN LUBBOCK

NOTES FROM THE "CHALLENGER"

III.

THE MILLER-CASELLA THERMOMETER

AT 8 A.M., on March 26, we sounded, lat. 19° 41′ N. long. 65° 7′ W., in 3,875 fathoms. The sounding was perfectly satisfactory, and left no doubt that the depth was estimated within a very small error. The "Hydra" sounding instrument was used weighted to 3 cwt. A slip water-bottle, and two Miller-Casella thermometers (Nos. 39 and 42) were sent down along with it as usual. The tube of the "Hydra" came up filled with a reddish clay containing a considerable quantity of carbonate of lime. The two thermometers were broken, and as the mode in which the fracture occurred is in itself curious, and has an important bearing upon the use of these instruments at extreme depths, I will briefly describe the condition of the thermometers when they came to the surface.

No. 39, a valuable instrument, with a small and constant error, which we had used for some time whenever

for any reason we required extreme accuracy, was shattered to pieces (Fig. 1).

In No. 42 this instrument was externally complete, with the exception of a crack in the small unprotected bulb on the right limb of the U-tube. The inner shell of the protected bulb was broken to pieces (Fig. 2).

In both of these cases there seems little doubt that the damage occurred through the giving way of the unprotected bulb. In No. 39 the upper part of that bulb was ground into coarse powder, and the fragments packed into the lower part of the bulb and the top of the tube. The large bulb and its covering shell were also broken, but into larger pieces, disposed as if the injury had been produced by some force acting from within. The thermometer tube was broken through in three places; at one of these, close to the bend, it was shattered into very small fragments. The creosote, the mercury, and bubbles of air were irregularly scattered through the tube, and it is singular that each of the steel indices had one of the discs broken off. The whole took place no doubt instantaneously by the implosion of the small bulb, which at the same time burst the large bulb and shattered the tube.

In No. 42 a crack only occurred in the small bulb, either through some pre-existing imperfection in the glass or from the pressure. When the pressure became extreme the crack yielded a little, and the sea-water was gradually forced in, driving the contents of the thermometer before it, and taking it at a disadvantage from within, breaking the shell of the large bulb, which was unsupported on account of the belt of rarified vapour between it and its outer-shell. The pressure was now equalised within and without the instrument, and the injury went no farther. Alcohol, creosote, mercury, and sea-water were mixed up in the outer case of the large bulb, with the debris of the inner bulb, and one of the steel indices lay uninjured across the centre of it.

It now becomes an important question why the thermometer should give way at that particular point, and one still more important, how the defect is to be remedied. At first sight it is difficult to imagine why the small bulb should give way rather than the outer shell of the large one. The surface exposed to pressure is smaller, the glass is thicker, and it is somewhat better supported from within, as the tube is nearly filled with fluid under the pressure of an atmosphere. I believe the cause must be that the end of the small bulb is the last point of the instrument heated and sealed after the tube is filled with liquid, and that, consequently, the annealing is imperfect at that point. It is evidently of no use to protect the small bulb in the same way in which the large bulb is protected. The outer shell is merely a precaution to prevent the indications being vitiated by the action of pressure on the elastic bulb. Against crushing, it is

FIG. 1

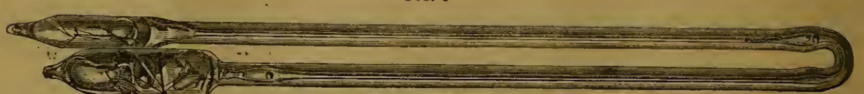

FIG. 2

no protection; rather a source of weakness, from its greatly increasing the surface. The only plan which seems to be feasible is to thicken the small bulb itself, and, if possible, to improve its temper. It is only fair to say that these thermometers were tested and guaranteed to only three tons on the square inch, and that the pressure to which they were subjected was equal to four tons.

WYVILLE THOMSON

NOTES

THE Albert Gold Medal of the Society of Arts has this year been awarded to M. Chevreul, Member of the Institute of France, and Director of the Gobelins and of the Jardin des Plantes at Paris, for his valuable researches in connection with Saponification, Dyeing, Agriculture, and Natural History, which, for more than half a century, have exercised a wide influence on the industrial arts of the world.

PROF. HUMPHRY announces that the Cambridge class for Practical Histology will meet during the months of July and August at the Anatomical Museum on Tuesdays, Thursdays, and Saturdays, at 9 A.M., commencing July 1. The Class for Human Osteology will meet on Mondays, Wednesdays, and Fridays at the Anatomical Museum at 9 A.M. during July and August, commencing July 2. The Professor of Zoology and Comparative Anatomy (Mr. Newton) announces that a class for practical work will be carried on in July and August by the Demonstrator in Comparative Anatomy, commencing July 2. The fee for the course will be one guinea.

THE following gentlemen have been recommended by the French Academy of Sciences to the Minister of Public Instruction for the four vacant posts in the Bureau des Longitudes:—M. Serret, M. Mouchez, M. Perrier, and M. Janssen.

THE Council of the Society of Arts having been informed that Her Majesty's Commissioners do not intend to publish reports on the different departments of the exhibition of the present year, have decided to undertake that duty, and for this purpose have engaged the services of gentlemen specially skilled in the subjects of the several sections, to prepare such reports for publication in the Society's *Journal*. A report on Ancient Objects, by Mr. C. Drury Fortnum, F.S.A., and another on Surgical Instruments and Appliances, by Mr. R. Brudenell Carter, F.R.C.S., appear in the *Journal* for May 30.

AT a meeting of the Council of the Leeds Naturalists' Field Club and Scientific Association, three of its members—Mr. Wm. Todd (vice-president), Mr. W. D. Roebuck (secretary), and Mr. John W. Taylor—were appointed a sub-committee to consider the best manner of collecting information for a series of catalogues of the natural productions of the district. The sub-committee having taken into consideration all the facts bearing upon the subject in hand, are of opinion that the following procedure should be adopted:—1. That in view of the approaching meeting in Bradford, in August next, of the British Association for the Advancement of Science, it is advisable that there should be produced by this society, and under its auspices, a brief account of the present state of our knowledge of the fauna, flora, and geological and topographical features of the district. 2. That for present use the most convenient district to illustrate would

be the one produced by striking a circle of ten miles' radius, having the Leeds Town Hall for its centre. 3. That, as far as practicable, the lists should be complete, and as full as possible in detail as to the distribution of the species; and that they should be prefaced by a good outline sketch of the physical conformation and geological structure of the district. In conformity with these recommendations, the sub-committee would be glad to receive lists, as complete as possible, from all persons willing to co-operate in the work. These lists, to be available for immediate use, must be sent in before the 1st of July, 1873. Should the amount of information received up to that date warrant the Council in so doing, the lists will be placed in the hands of small committees of revision, whose province it will be to construct general catalogues combining all the information in the possession of the Society; and it is then hoped that during the first week in August, a small work may be published. The sub-committee will be very glad to receive all suggestions that may be made; and would be glad also to learn the names of all persons likely to be able to supply information. All communications to be addressed to the Secretaries, 9, Sunny Bank Terrace, Leeds.

WE have received the Report, for 1872, of Mr. B. A. Gould, superintendent of the Argentine National Observatory at Cordoba, and a very creditable report it is, both to Mr. Gould and his assistants, as well as to the liberality of the Argentine Government, which seems to have done all in its power to provide the necessary buildings and instruments. The buildings are not yet quite complete, though a number of excellent instruments have been acquired, and others are being provided. The principal work of the observatory has been the preparation of a Uranometry, which will contain a larger number of stars than the recently published one of Heis for the northern heavens; Heis's contains 5,421 stars. In the Uranometria Argentina, the brilliancy of the stars will be determined to single tenths of a limit of magnitude. There now remains nothing of importance to be done in the way of observation, since each star has been observed upon the average at least four times, and the degree of its brilliancy determined with the greatest precision possible. To prepare these results for publication, the position of every star will be computed for the commencement of 1875, a part of which labour has already been accomplished, and then to prepare the maps for reproduction by the engravers. The observation of the zones for the formation of an extended catalogue of stars between the 23rd and 80th degree of south declination, was commenced in September last, and is being carried on satisfactorily; as also is the photographic work of the observatory, a very considerable number of photographic impressions of clusters of stars having been made, which only need a knowledge of their zero of position to render them serviceable. Means are also taken to spread a knowledge of the exact time at regular intervals throughout the Confederation. Altogether the Argentine Observatory appears to be exceedingly efficient.

WE have received from Prof. A. Kerner, of Innsbrück, several interesting contributions to systematic and physiological botany —"Ueber die Schafgarben-Bastarte der Alpen," an account of the hybrid yarrows found in the Tyrolese Alps; "Novæ Plantarum Species, Decas iii.," containing descriptions of new Rubi of Austria and the Tyrol; and "Chronik der Pflanzen-wanderungen," in which he narrates the curious circumstances connected with the spread of a North-American plant, *Rudbeckia laciniata.* This plant first became known in Europe early in the seventeenth century, when it was introduced into the gardens of Paris; during two centuries and a half it has gradually spread over the gardens of nearly the whole of Europe, but appears only within the last twenty or thirty years to have escaped, and within that short space of time has become completely naturalised in a great number of places. In a communication to the Scientific and Medical Society of Innsbrück, Dr. Kerner states, as the result of his observations on Alpine plants, that the growth of the stem and even of the flowers of many species proceeds at the temperature of zero C.; the flowers may in some cases open, and even mature their pollen, beneath a thick covering of ice, the surface of the glacier being penetrated in innumerable places by their stems.

DR. A. KERNER reprints from the Proceedings of the Scientific Society of Innsbrück an interesting paper on the means of protection of the pollen of plants against premature displacement or damp. As the vitality of pollen is immediately destroyed by exposure to the action of either rain or dew, he finds in nature a variety of contrivances to protect it against these injurious influences during the interval between its escape from the anther and its being carried away by insects, these contrivances being generally absent in those plants where fertilisation is effected by the pollen being conveyed at once to the stigma by the wind. In plants with coherent pollen, fertilised by insect agency, where some of the anthers are so placed as to be necessarily exposed to the weather, these are generally found to be barren, or destitute of pollen, and where they would interfere with the entrance of insects into the flower, they are altogether abortive or rudimentary. Plants with coherent pollen, which require insect agency for their fertilisation, Dr. Kerner believes to be of more recent geological occurrence than those with powdery pollen, which require only the wind to convey it to the stigma.

THE proceedings of the Asiatic Society of Bengal contain remarks on winds, typhoons, &c., on the south coast of Japan, by Commander H. C. St. John, H.M.S. *Sylvia.* The most prevalent winds in the southern parts of Japan are from the north-east. Throughout an entire year the proportion was as follows, taking 1,000 hours as an index:—Between N. and E., 500; between N. and W., 200; between S. and E., 100; between S. and W., 0·99. During April, May, June, July, August, and September, N.E. winds prevail, hauling more easterly in June, July, and August. In August and September S.E. winds are more frequent than during any other months. In October variable winds prevail, and the N.W. wind begins. During November, December, January, and February the N.W. winds prevail and blow hard. In March the N.W. and N.E. winds are equally distributed. The S.W. winds most frequently occur during the early parts of September. It appears the winds on the southern coasts of Japan are easterly during April (spring), and hauling to the S. as the summer approaches, pass through S. and W. to N.W. during winter, coming again through N. to N.E. and E. in spring and summer. Typhoons occur between June and October, inclusive. From the middle of August to the middle of October they may be expected to occur most frequently. The usual tracks of these storms on the Japan coasts appear very regular; approaching from the S.E. travelling about N.W. On reaching the hot stream in about the latitude of the Bonin Islands, or between here and the Foochoo Islands, they begin to curve to the north, and following the course of the Kuro Siwo, strike the south coasts of Nipon. Owing chiefly to the high land along the coast, the northern disc of the storm becomes much flattened in, causing more easterly wind than would occur if the storm were in mid ocean. Retaining the course of the stream, they pass along in a north-easterly course, and, if not broken up previously, pass out into the Pacific Ocean on reaching Inaboya saki.

MR. JAMES WOOD-MASON has sent us a description of a Macrurous Crustacean, which he has made the type of a new genus, *Nephropsis Stewarti.* The specimen (a female) he

describes was dredged in from 250 to 300 fathoms, about twenty-five miles off Ross Island on the Eastern coast of the Andamans. It is clearly allied to *Nephrops Norvegicus* of Northern European seas, its main difference being the absence of the squamiform appendage of the Antennæ. One of the most interesting points about the new crustacean is the loss of its organs of vision by disuse, a characteristic of several recently discovered crustaceans; this is compensated for by the great length and delicacy of the antennæ, and the great development of the auditory organs, the animal's habits being to burrow in the mud at the depth of about 300 fathoms.

It may be recollected that M. Alphonse Pinart, the French philologist, visited the Aleutian Islands and Alaska in the summer of 1871, for the purpose of collecting the vocabularies and the photographs of the different tribes. This material he carried back with him to Paris, where he has been engaged in working it up. We learn that he expects to revisit the United States this month, with ample funds in his hands from the French government, in order to effect an exhaustive collection of the antiquities of Alaska, his excursions to the different islands being made in a vessel especially fitted up for his use. Alaska is one of the finest fields in the world for ethnological and prehistoric research.

Professor Wyman has concluded, as the result of explorations among the shell mounds of Florida, U.S., during the past winter, that the aborigines by whom they were constructed must have been decided cannibals, as in eight different instances he has found considerable quantities of human bones in the shell heaps, the bones themselves being broken up and split, just as in the case of the bones of other animals. This, he is satisfied, was not the result of burial, but was done for the purpose of obtaining the marrow, probably after the flesh had been devoured.

Under the auspices of the Society of Biblical Archæology it is intended shortly to publish a series of translations of all the important Assyrian and Egyptian texts which exist in the various collections of England and the Continent, and thus place before the English student the remains of undoubtedly the oldest and most authentic literature in the world. Nearly all the principal translators have offered their services for this purpose, and while each author will be alone responsible for his portion of the work, the general arrangement of the materials will rest with the president of the society. The selection of the records will embrace the entire range of Egyptian and Assyrian history and literature. Each translation will quote the authorities upon which it is based, or the monument from which it is taken, and all other notes will be as few and brief as possible, to avoid controversy and expense. The first volume will be issued by Messrs. Bagster and Sons, at a price to bring it within the reach of all interested in such subjects.

The *conversazione* of the Society of Arts will be held at the South Kensington Museum on Friday evening, June 28.

The late distinguished chief of the U.S. Coast Survey, by his will, established a fund to be placed in the hands of executors, by whom the income is to be expended, under the direction of a committee of the National Academy of Science, for the advancement of some branch of physical research. The first report of results achieved through this bequest was recently made to the Academy by its President, Professor Joseph Henry. The committee had decided that in view of the great interest that Professor Bache had throughout his life manifested in terrestrial magnetism, it would be highly proper to further this science by gradually extending over the country the magnetic survey which, during his own lifetime, he had carried out in the Middle States. In the execution of this design they had been so fortunate as to secure, at small expense, the services of Dr. Hilgard, of St. Louis, by whom, in 1872, chiefly in the season most favourable for travelling, quite a large number of stations were occupied for the determination of the magnetic elements. These stations are mostly in the Southern States, and it is the intention of the committee to extend the work annually, northward and westward, as the income from the fund may allow.

The U.S. Army Signal Office has made preparations for a great extension of its valuable system of reports of the heights of rivers, particularly of all those opening into the Mississippi. Over twenty-five stations are now established at suitable points on these rivers, especially, of course, on the Ohio, Missouri, and Mississippi. They are provided in some instances with automatic self-recording apparatus, and at all other places the observation of the height of the water is taken eight times daily when floods are apprehended. By this most beautiful system every wave of high water is accurately followed in its course down stream, and the approach of dangerous high floods is easily foretold by the repeated telegraphic reports. The system of river reports, which has been in operation during the past year, has given such universal satisfaction to those navigating the Western waters that the demand for increased facilities can only be met by this new and far more elaborate system of stations.

The results of the explorations in the Gulf of St. Lawrence prosecuted during the months of July and August, 1872, by Messrs. Whiteaves and Bulger, have just been published. The area examined extended from a little above Cape Rozier to the Magdalen Islands. A depth of water somewhat over 200 fathoms was found near the centre of the mouth of the St. Lawrence, between Cape Rozier and the south-west point of Anticosti; the greatest depth actually met with was 313 fathoms, about half-way between the east point of Anticosti and the Bird Rocks. Large collections were made, embracing several species new to science. Among the novelties discovered was a sponge belonging to a genus but recently indicated in the "Depths of the Sea." About thirty-five species of corallines were obtained, large numbers of them being new. Numerous fine specimens of *Virgularia* were procured, the same kind having been found by Dr. Packard on the Georges Bank, and three species of sea-anemones were secured in addition to those of last year's collection. Two undescribed specimens of a coral (both dead) were also gathered at a considerable distance from each other. The relations of these new species are rather to the tropical forms than to those which we already know on the coast of the North Atlantic.

A shock of earthquake, lasting for several seconds, was felt at Attok on the morning of Sunday, April 27.

We have been favoured with a copy of the *Japan Gazette*, from which we take the following notes:—A huge cephalopod is now being shown in a house near the temple at Asaka, Yedo. It seems that a fishing-boat was seized by its tentacles whilst off the village of Kononoto, in the district of Kisaradzou, and that the boatmen killed the creature by repeated blows. Its length from the tail to the insertion of the tentacles is about sixteen feet; one of the arms is from its junction with the body to the sucker at its point nearly five feet. The polypus has shrunk since its death, so that living, it would probably measure considerably more.—The anomalous absence of earthquakes during the past winter has excited some speculation as to the causes of such quiet, in a country usually very tremulous towards the coming of spring. Whatever may be the real causes, the remarkable volcanic activity in Japan, during the past winter, and at present, is an interesting collateral phenomenon. From nearly all parts of the empire, during the last two months, have come tidings of

mountains quaking and bursting in fissures, volcanoes casting out stones, ashes, and mud, and in some instances, flame and hot lava. Smoke and steam from Asamayama have been visible from Yedo, several times this winter. In addition to the eruptions in Yechiu, Mito and Higo, the latter being especially severe and damaging to the cultivated land around it,—another mountain is reported as being affected with volcanic symptoms. Kurokami-yama, near Nikko, which has, so far as is known, always been very quiet, was shaken with a great shock on March 12, at 3 P.M. The shock was accompanied by loud noise, and a strong smell of sulphur, which remained about six hours.

ADDITIONS to the Brighton Aquarium during the past week: a Porpoise (*Phocæna communis*) from Rye Bay; a Sturgeon (*Accipenser sturio*), 6 feet long, captured by the Bognor fishermen; Smooth Hounds or Skate-toothed Sharks (*Mustilus vulgaris*); White Hound or Toper (*Galeus canis*); Thornback Skate (*Raja clavata*); Sting Rays (*Trygon pastinaca*); Grey Mullet (*Mugil capito*); Flounders, fresh-water variety (*Pleuronectes flesus*); Butterfish or Gunnel (*Centronotus gunnellus*); Allis Shad (*Clupea alosa*); Salmon (*Salmo salar*); Ballan Wrasse (*Labrus maculatus*); Crabs (*Cancer pagurus*); (*Portunus puber*); (*Polybius Henslowi*); (*Carcinas Mœnas*); Zoophytes (*Actinoloba dianthus*); (*Tealia crassicornis*); (*Sagartia miniata*); (*S. nivea*).

THE additions to the Zoological Society's Gardens during the past week include a Bengalese Cat (*Felis bengalensis*) and two Indian Crows (*Corvus splendens*) from Arracan, presented by Mr. W. Dunn; a New Caledonian Rail (*Ocydromus lafresnayanus*), presented by Dr. G. Bennett; an Indian Porphyrio (*Porphyrio indicus*) from the Navigator's Islands, presented by Rev. J. Whitmee; a dwarf Chameleon (*Chameleon pumilis*) from South Africa, presented by Miss Siddons; an African Tantalus (*Tantalus ibis*); three Molucca Deer (*Cervus moluccensis*); a Vociferous Sea Eagle (*Haliaëtus vocifer*) from Africa; a European Lynx (*Felis lynx*), and a Glutton (*Gulo borealis*) from Norway; a collared Amazon (*Chrysotis collaria*) from Jamaica; two common Spoonbills (*Platalea leucorodia*) from Europe, and two Wattled Cranes (*Grus carunculatus*) from South Africa, purchased; an American White Crane (*Grus americana*), received in exchange; three American Mocking Birds (*Mimus polyglottis*) hatched in the Gardens; and an Australian Thicknee (*Oedicnemus grallarius*) deposited.

SCIENCE IN ITALY

THE Transactions of the Academy of Sciences of the Institute of Bologna for the academical year 1871-2 contains twenty-nine memoirs read by members at the sittings of the Academy and several communications from without. I find it quite impossible to do justice to these without exceeding permissible limits, but will briefly refer to a few.

In a paper on a probable connection between solar eclipses and terrestrial magnetism, Dr. Michez, after describing the magnetic phenomena observed in Italy and more especially in Sicily during the eclipse of December 22, 1870, and pointing out the difficulty of separating the disturbances due to the eclipse from those otherwise produced, states the result of his laborious and careful study of the Greenwich magnetic records in relation to the passage of the lunar shadow over any part of the earth. Having determined the average *ordinary* declination and amount of agitation for the particular hour and season corresponding to that of each eclipse, he compares these with the declination and agitation observed while an eclipse was in progress, and collecting all these results and averaging the deviation of the eclipse periods from those of ordinary corresponding times, he concludes that an eclipse of the sun exercises a real influence on the declination needle, that this influence extends through several hours before and after the period of greatest solar obscuration, and that it is manifested by a greater agitation of the needle, and an eastward deviation. Upon theoretical considerations, Dr. Michez shows that the moon's shadow regarded in its relations to humidity should always produce an eastward deviation, but as regards the magnetic properties of oxygen should produce either an eastward or westward deviation, according to the position of the place of observation in relation to the shadow. Assuming that the latter, on a sufficiently large average, will neutralise each other, the residual phenomenon should be a slight eastward deviation.

In a paper on "The Climate of Europe during the Glacial Epoch," Dr. Bianconi, following De la Rive and Villeneuve, shows that the glacial extension of that period may have been due to greater humidity of climate rather than a lower mean temperature. Dr. Bianconi's conclusions are almost identical with those I suggested about fourteen years ago when describing a curious summer accumulation of ice in a previously unvisited Norwegian valley, where the snow line is actually lowered to an extent of about 3,000 feet, simply by a local increase of atmospheric humidity caused by the drifting spray of a double waterfall.* The subject was subsequently treated by Dr. Frankland in a lecture at the Royal Institution.

Prof. Filopanti contributed an interesting paper on the movements of the atmosphere, in which, after referring to the conclusions of Maury, that on both sides of the equator up to about the 30th parallel constant easterly winds prevail, from the 30th to the 35th variable winds, but still with the easterly predominating; from the 35th to the 40th, variable wind, with a commencement of westerly prevalence; and from the 40th to the Pole westerly winds decidedly prevailing. The object of Prof. Filopanti was to find a theoretical reason for these particular limits. To do this he regards the atmosphere as subject to the operation of two forces, viz. the resistance of the earth, and the mixture of aërial columns due to variations of temperature of the earth's surface. If only the first of these influences operated, the atmosphere would ultimately partake in every part of the velocity of the terrestrial parallel on which it rested, and there would be no sensible winds; if only of the second, the atmosphere would ultimately acquire throughout an absolutely equal velocity of rotation. He works out mathematically the amount of this velocity, and finds it equal to that of the surface of the earth at the latitude 35° 50′ 52″, which is a close approximation to the 35° of Maury. This he considers would be the uniform velocity of the air if the land and the sea were perfectly smooth, and he therefore designates the parallels of 35° on either hemisphere the "neutral parallels." Hence we are justified in theoretically anticipating that between the neutral parallels and the equator actual mean rotatory velocity of the air will be less than that of the earth, that is, the prevailing winds will be easterly, and that between the neutral parallels and the Poles the prevailing winds should be westerly, as there the mean rotatory velocity of the air should exceed that of the earth. The friction of the earth will be continually struggling to correct these differences of velocity, while the north and south movements, due to differences of temperature, will contest for their maintenance and augmentation. Prof. Filopanti goes further into details of special atmospheric currents to illustrate and confirm the above, but space will not permit me to follow him there. I have, however, so far sketched in abstract his leading idea as it appears to be an important contribution to the theory of atmospheric movements, and as far as I know is original. To some extent it is applicable to the vexed question of ocean currents.

The "Hermaphroditism" of eels has occupied a good deal of the attention of the Bolognese Academicians. Prof. Ercolani described a number of his own observations and experiments, showing that this hermaphroditism is "perfect," and the subject was further discussed at two subsequent meetings, when the results of previous researches of Vallisneri, Valsava, Allesandrini, Mondini, and others, were stated and compared. Besides the above and some others on subjects of general interest, are a few purely mathematical papers, and several on pathological, medical, and local subjects, which I must pass over.

Considering that Bologna itself is but a provincial town, and that the whole province of Bologna contains a population about equal to that of Birmingham, these Transactions of the Bologna Academy of Sciences indicate an amount of scientific activity in the highest direction of scientific research that we are unable to rival in any corresponding provincial district of Great Britain.

W. MATTIEU WILLIAMS

* "Through Norway with a Knapsack," Chap. xv.

SCIENTIFIC SERIALS

Bulletins de la Société d'Anthropologie de Paris, 1871–72.—We find from these reports that the French palæontologists have been unusually active during the last eighteen months in continuing the exploration of the numerous bone-caverns of their country and in testing the accuracy of the older classifications of their remains. M. Barabeau has been examining with great care the Dordogne district, which has become classic ground through the labours of Christie and Lartet. M. Saudon believes that the molars and maxilla recently found at Laugerie-Haute cannot be referred to the true horse—although they may provisionally, like similar remains found by M. Rivière in Italy—be accepted as belonging to some form of *equus*, for he does not think that the horse existed in Europe in pre-historic times. M. Mortillet, in obedience to the suggestions of M. Bertrand, Conservateur du Musée de S. Germain, has drawn up a chart of the palæolithic age in Gaul, the only work of the kind extant: in it are recorded 5 localities in which occur supposed traces of man in the tertiary; 43 alluvial deposits in the quaternary yielding human bones and industrial remains; and 278 caverns containing quaternary fauna with traces of pre-historic man. M. Mortillet thinks that we are no longer justified in assuming with E. Lartet that there was ever a special age of the bear or reindeer, all extinct animals having apparently lived through the whole palæolithic period. Amongst the numerous communications of M. Hamy, we may instance papers on the "Fossil Human Remains of d'Engihoul, near Liège;" "The Anthropology of Cambodia;" "The Quaternary Deposits of cut Silex recently discovered in the Pas de Calais;" "The Existence of Brachycephalic Negroes on the Western Coasts of Africa;" and "The Proportions of the Arm and Fore-arm to the different periods of Life." M. Doulish, from observations made at the close of 1871, in a bone cavern at Corgnac (Dordogne), believes that he has found incontrovertible proofs that man in the reindeer age had attained the art of *polishing* no less than of cutting stone.—M. Lagardelle communicates through M. Hamy, one of the Secretaries of the Society, some curious information in regard to the habitations of the degraded people known under the names of *Colliberts*, *huttiers*, &c., who for many ages occupied the marshy lands of Poitou, near the mouths of the Sèvre, and whose descendants were known till recently as *nioleurs*. This district was occupied by Gauls before the Norman Conquest, and after that event it became, from its inaccessible character, a place of refuge for fugitives. In the eleventh and twelfth centuries the Colliberts, whose special occupation was fishing, were dependent, as *homines conditionales*, on several religious houses, but were nevertheless left in a state of heathen, almost savage ignorance. Their huts were made of interlaced willow twigs, and their only means of locomotion before the formation of the network of canals, which have proved the chief agents in rescuing them from their isolation, were their long ash stilts and the so-called *nioles*, or light boats from which they took their name. The race is now merged in that of the contiguous *terra firma*.—M. Alph. Milne-Edwards has prosecuted an extensive series of observations on "The Embryology of the Lemurians and the zoological affinities of those animals;" and he finds that the placental system differs so widely from that of the Simiæ, with which they have been supposed to present very close relationships, that he is of opinion the Lemurs should take an intermediate, but wholly distinct, place between monkeys and carnivores.—M. Thorel's medical notes of his observations while serving in the exploring expedition to Meekong, in 1870, afford curious information in regard to the immunity to certain miasmatic affections presented by the people of Cochin China and other parts of Indo-China.—M. Sanson has laid before the Society his views on the Characterisation of Species, which are diametrically opposed to the Darwinian theory of evolution. The earlier numbers of the *Bulletins* for 1872, contain an unusually large proportion of papers on purely anatomical, psychological, medico-legal and similar subjects.—M. Broca considers, in a special mongraph, the importance of nasal configuration as a true ethnological character.—M. A. Roujou traces the analogies of the human type with that of the more ancient mammals, and proceeding to the length of concise definition, he fixes the probable appearance of the first lemurians at an epoch very remote from the secondary, and of monkeys—properly so called—before the tertiary, at the beginning of which period he thinks it not improbable that they engendered man.—The second and third numbers of vol. vii. of the *Bulletins* contain the exhaustive Treatise of M. Topinard on the indigenous races of Australia, with the valuable contributions and discussions in regard to the same subject by MM. Broca, Hamy, and Rochet. These numbers give us a general exposition of the progress and actual position of the science of Anthropology, and of the social advancement of our civilisation and its effect in obliterating ethnological characters and in elevating the lower type.

THE *Lens* for April commences with an analysis of the species of the genus *Amphora*, by Prof. H. L. Smith, in continuation of his Conspectus of the Diatomaceæ, accompanied by three excellent plates, and containing the description of nearly 100 species.—Dr. Danforth, of Chicago, describing "The Cell," developes Dr. Beale's theory respecting the nature of the nucleus, and discusses the action of carmine upon it.—Mr. H. Babcock, "On the Flora of Chicago and its Vicinity," catalogues the gramineæ and filices of that place very shortly.—There are also papers by Mr. J. H. Martin, "On the Similarity of various forms of Crystallisation to minute Organic Structures;" and by Mr. E. Colbert, "On the Figure of the Earth, and its Effect on Observations made in the Meridian."—The editor criticises the test employed by a committee of the Royal Microscopical Society of London in their decision respecting the angular apeiture of Mr. Tolles's $\frac{1}{10}$th objective, thinking it unfair.

SOCIETIES AND ACADEMIES

LONDON

Royal Geographical Society, May 12.—Major-General Sir H. C. Rawlinson, K.C.B., president, in the chair.—The paper read was "Journey through Western Mongolia," by Mr. Ney Elias. The distance travelled over was 2,000 miles, accomplished between July 1872 and January 1873. The route from Kalgan (the starting-point in crossing the desert of Gobi by the usual route *viâ* Urga to Kiachta) was westerly to the Chinese frontier town of Kwei-hua, thence north-westerly to the river Onghin, and afterwards again westerly, along the foot of the Khangai Range, to the city of Uliassutai, which his observations showed to be 5,700 ft. above the sea-level. His further journey was impeded by the bands of Mahommedan Mongol rebels, the so-called Dungans, who, although badly armed, struck terror into the Chinese garrisons of the towns, and carried fire and slaughter wherever they went. He narrowly escaped the band, which a few days before his arrival destroyed the city of Kobdo, west of Uliassutai; arriving there, he saw the charred remains of the outer town and the unburied bodies of slaughtered people scattered over the streets. The Chinese garrison still occupied the fort, and received him and his party with kindness. All his endeavours, however, to obtain assistance for his further journey southward and westward to Kuldja were met by steady opposition, and he finally had to cross the frontier to the Russian town of Büsk. The president informed the meeting that Mr. Elias had not only accomplished a wonderful journey over a tract of Central Asia never visited by a European since the times of Marco Polo, but had executed, unaided, a survey of the whole route travelled. His very numerous observations for longitude and latitude had been computed by Mr. Ellis, of the Greenwich Observatory, and those for heights above the sea-level by Mr. Strachan, of the Meteorological Office. For this great service rendered to geographical science, the Council of the Society has just awarded him the Founder's Gold Medal for 1873.

Meteorological Society, May 21.—Dr. J. W. Tripe, president, in the chair. The discussion was resumed on the following questions, which had been submitted to the consideration of the Meteorological Conference at Leipzig in August last:—No. 18: Can uniform times of observation be introduced for the normal observations? Remarks were made by the president, Dr. Mann, Messrs. Glaisher, Symons, Sopwith, Scott, Bicknell, Salmon, and Strachan, as to whether local or Greenwich time should be used, and whether the hours of 9 A.M. and 9 P.M., or 9 A.M., 3 P.M., and 9 P.M. should be recommended to observers. The meeting was of opinion that the hours of obseivation should be 9 A.M. and 9 P.M., and that local time should be adopted. The next question considered was No. 20: Division of the year for the calculation of mean results. After some discussion Mr. Sopwith suggested that a committee should be appointed to draw up a series of questions on all matters connected with this subject, and that the same be sent to the Fellows of the Society requesting their reply on all or any of the questions; this suggestion was approved of and adopted by the meeting.—A

paper was then read on "Land and Sea Breezes," by Mr. J. K. Laughton, who was of opinion that sufficient attention had not been paid to the subject; and that more careful examination would show that the ordinary recorded theory is not in accordance with the facts observed; that these prove that sea and land breezes are seldom strong where the land is of that arid nature which gives rise to extreme differences of temperature, and that they frequently are strong where, from the verdant nature of the country, the differences of temperature are trifling; also that the sea breeze begins out at sea, and comes slowly in, and that the land-breeze comes, in the first instance, distinctly off the land, sometimes as sharp squalls. The necessary conclusion from these observations is that the breezes are winds of propulsion, not of aspiration; and whilst it seems probable that the propelling-force, in the case of the sea-breeze, is due to the rapid formation of vapour over the sea, the land-breeze may be the reaction, or return of the column of the air which has previously been forced upwards by the sea-breeze. A short paper by Rev. F. W. Stow, on the same subject, was read, giving an account of the observations he had made at Hawsker; after which Mr. R. H. Scott gave a description of a double rainbow observed at Kirkwall.

Institution of Civil Engineers, May 13.—Mr. T. Hawksley, president, in the chair.—The paper read, "On the Delta of the Danube, and the Provisional Works executed at the Sulina Mouth," by Sir Charles Augustus Hartley, was a sequel to a previous communication by the author on March 11, 1862. It described the mutations of the Sulina Bar from 1861 to the present time, and referred to the changes in the Sea outline of the Delta during sixteen years. Reference was made to the enormous growth of the northern part of the Kilia Delta in recent years, due to the greatly augmented volume of water which had lately flowed to the sea by the Ochakoff branch and New Stamboul Mouth; while a diminution in the advance of the southern extremity of the Kilia Delta was assigned to the impoverishment of the old Stamboul branch of the river. These changes, from natural causes, in the relative volumes of water delivered to the sea by the Kilia Mouths, were favourable circumstances in considering the problem of the number of years that would probably elapse before the Sulina Mouth would be absorbed in the shallows of the Kilia Delta. Since 1857, owing to the shoaling of the Toultcha and the St. George's branches, the outflow by the Kilia had increased, so that it now delivered two-thirds of the whole volume of the Danube to the sea. Fortunately for the navigation by the Sulina Mouth, the larger portion of the detritus was transported far to sea, and comparatively little went to swell the shallows of the Kilia Mouths. In the last fifteen years the advance of the 30-feet line of soundings had been strictly confined to the sandbanks facing the mouths of the Kilia, Sulina and St. George, and it was shown that an erosive action had been long at work on the shore line and sea bottom to the north and south of the Sulina Mouth.

Society of Biblical Archæology, June 3.—Dr. Birch, F.S.A., president, in the chair. The folowing papers were read:—"The Legend of Ishtor descending to Hades." By H. F. Talbot, D.C.L., F.R.S., &c.—In this valuable paper the author translates from the tablets the Goddess's voluntary descent into the Assyrian *Inferno*. In the cuneiform it is called the Land of No Return; and the Lord of Earth gives her a green bough of the *Li*. . .tree to protect her life (comp. Virgil's Æneid). Ishtar passes successfully through the seven gates, compelled to surrender her jewels, (1) her crown, (2) her ear-rings, (3) her head-jewels, (4) her frontlets, (5) her girdle, (6) her finger and toe rings, (7) her necklace. The Lord of Hades seeing her sends his messenger Namtar to greet her. But as she cannot return of her own accord to the upper regions, the heavenly triad Sun, Moon, and *Hea* or Hu (Lord of Mysteries) consult, and *Hea* raises a black phantom who performs a juggler's trick before the Lord of Hades; during which he gives to Ishtar a cup full of the Waters of Life, whereby she returns to the upper world, receiving at each Hades-portal the jewels she had been deprived of in her descent. The phantom is rewarded by the most exquisite meats, wines, &c. The Greek Fate *Atropos* is supposed by the author to mean No Return, and Hades (House of Eternity) is compared with the Hebrew *Od* and *Bet-Moed* of Job xxx. 23.—"On the Egyptian Preposition," by M. P. Le Page Renouf, F.R.S.L.—"On a Remarkable Babylonian Brick described in the Bible," by Richard Cull, F.S.A.

PHILADELPHIA

Academy of Natural Sciences, February 11.—Dr. Ruschenberger, the president, in the chair. Mr. Thomas Meehan presented an apple, which was borne by a tree at Kittaning, in Pennsylvania, and which tree never produced any flowers in the popular acceptation of the term; but always yielded an abundance of fruit. The specimen furnished a practical illustration of some morphological truths which could not often be demonstrated in the way this afforded the opportunity of doing. It was admitted that a fruit was a branch with its accessory leaves transformed. The apple fruit was made up of a series of whorls of leaves comprising five each. Cutting an apple through we found a series of five formed the carmels containing the seeds. Several series of whorls, very much retarded in development, probably formed the stamens, but this could not be well seen in the apple fruit, as they seemed to be almost absorbed in the corolla series. This was the next in order that appeared in the divided apple—the green curved fibrous line which we find in all apples midway between the "core" and the "rind" is the dividing line between the series which forms the corolla, and the outer series which forms the calyx. In this tree there are no pistils, the series which usually goes to make up this part of the fruit structure being either very rudimentary or entirely wanting. Hence there was no core to the fruit. The result of this want of development was that the usual calyx basin of the apple was in this case occupied by a cavity three-quarters of an inch across. There were no petals; but in place five gland or rather bud-scalelike processes, at regular distances, on the edge of the green fibrous outline before referred to. The outer whorl, which usually forms the calyx, was almost asepalous, as a mere scarious membrane marked the place where the calyx segments or sepals should have appeared. It was so easy in this specimen to trace the dividing line between the outer or calycine whorl and the inner or corolline whorl, which, uniting and becoming succulent, formed the popular apple fruit, that it was worthy of note in this connection. But the most interesting feature in this specimen was what were probably, from their similarity in appearance, cork cells, formed abundantly on the outside of the apple. It would seem that, with the lack of development in the inner series of whorls necessary to the perfect fruit, those which remained were liable to take on somewhat the character of bark structure.

February 18.—Dr. Ruschenberger, the president, in the chair.—The following paper was presented for publication:—"Description of Mexican Ichneumonidæ, Part II," by E. T. Cresson.—Mr. Thomas Meehan presented specimens of leaves of a Begonia on which minute folioles appeared as densely as hair all over the upper surface, while the leaf was on the growing plant. The little growths first appeared as succulent hairs, and these hair-like processes subsequently divided or produced the leafy blades from their apices. Mr. M. remarked that hairs were at any rate structurally but graded thorns, of which bristles were an intermediate stage. Spines often bore leaves, but it was unusual for thorns to do so. It might not be that these leaf-bearing processes were really hairs though they had that appearance.—Mr. Thomas G. Gentry called the attention of the Academy to what he considered to be an interesting case of a change of habits which had recently occurred in the life of an ordinary chickaree, the *Sciurus hudsonius* of Pallas. During the early part of last autumn, his attention was called to the fact that the birds in a certain designated locality of Mount Airy, during the hours of the night, were undergoing a system of wholesale destruction, the work of small animals which were supposed to belong to some species of Carnivora. Labouring under this impression, and being desirous of securing a specimen or two, he started for the scene of slaughter, bent upon discovering the name and character of the animal; when within a few rods of the place, the almost deafening noise that greeted his ears, from the tall trees, led him to suspect that all was not right. After reaching the spot, a few moments of anxious waiting sufficed to reveal to him the cause of the noise and the origin of the sacrifice above alluded to; for, sitting upon a twig just above his head, he observed a *chickaree*, holding in its paws a bird which it had captured, and from which it was very contentedly sucking the life current. It is a well-established fact, he further remarked, as far as he had been able to verify it, that the numerous species of Rodents, with but two exceptions at the most, subsist principally or entirely upon vegetable matter, especially the hard parts of plants, such as nuts, bark, and roots. This habit of imitating the propensities of the *Mustelidæ*, he thought might have arisen

from the habit which some squirrels possess, possibly the one under consideration, of sucking the eggs of birds; the blood-sucking habit he assumed to be an outgrowth from the other. This adoption of another's mode of life by *S. hudsonius*, he thought a discovery of some note, as usurpation of habits, leading to functional and structural changes in an animal's economy, is accounted an element of no mean weight in the *development hypothesis*, according to the testimony of able writers upon Evolution.—Prof Cope exhibited the cranium of the horned Proboscidian of Wyoming, *Loxolophodon cornutus*, and made some remarks on its affinities (see NATURE, vol. vii. p. 471).

CALIFORNIA

Academy of Sciences, April 21.—Prof. Davidson, president, in the chair.—Dr. Blake read a paper on the connection between the atomic weights of inorganic compounds and their physiological action. In a communication read before the Academy of Sciences of France, February 10, Messrs. Rabuteau and Ducoudray state that the poisonous effects of metals is greater as their atomic weight increases. When the different elements are grouped according to their isomorphous relations, there evidently exists a close connection between the *intensity* of their physiological action and relative atomic weights, and it is only under such conditions that the statement of Messrs. Rabuteau and Ducoudray is even approximately correct. That no absolute connection exists between the atomic weight of a metal and its physiological action is evident; for instance, the compounds of Beryllium with an atomic weight of 9· are far more poisonous than the salts of silver with an atomic weight of 103. As an example of the connection between the atomic weight and the poisonous qualities of a substance, the following table, drawn up from experiments which have not yet been published, furnishes strong evidence. The experiments were performed on rabbits, a solution of some salt of the metal being injected into the jugular vein.

Name of substance.	Atomic weight.	Quantity required to kill
Lithium	7	40 grs.
Sodium	23	20 ,,
Rubidium	85	6 ,,
Cæsium	133	8 ,,
Thalium	204	3 ,,

—Mr. Edwards presented a paper on the honey-making ant of Northern Mexico. The community is divided into three classes—the workers, carriers, and the honey-makers. The workers are much larger than the others, and of a black colour; they guard the nest and convey to it the materials from which the honey is made; these they deposit in a leaf over the centre of the nest, and from this leaf it is transported by the carriers to the honey-makers in the interior of the nest. The carriers are much smaller than the workers, and of a light brown colour. The honey-makers resemble the carriers in size and colour, with the exception of the enlarged abdomen. They are found in the centre of the nest, generally at a depth of two or three feet from the surface. They are supported on a sort of web made of closely woven fibres. Each ant occupies a superficial indentation in the web, in which it remains; in fact all locomotion in the honey makers is impossible, as the distended abdomen, which constitutes the honey-bag, is at least twenty times as large as the rest of the body. The honey is of a fine flavour, and much sought after by the natives.

PARIS

Academy of Sciences, May 26.—M. de Quatrefages, president, in the chair.—The Academy proceeded to the election of the candidates to be recommended to the Minister of Public Instruction for the four vacant posts in the Bureau des Longitudes. The following were the final results:—Member representing the Academy of Sciences, 1st line, M. Serret; 2nd line, M. O. Bonnet: Member of the Marine Department, 1st line, M. Mouchez; 2nd line, M. Bouquet de la Grye: Member of the War Department, 1st line, M. Perrier; 2nd line, M. Blondel: Geographical Member, 1st line, M. Janssen; 2nd line, M. d'Abbadie. The following papers were read:—On the assimilability of super-phosphates, by M. Joulie. The author found that "super-phosphate" consists of the following four bodies:—Free phosphoric acid, dihydric calcic phosphate, hydric dicalcic phosphate, and tricalcic phosphate. The first three of these can be taken up by plants; hence he decides, (1) that the amount of phosphoric acid soluble in water is not a true estimate of the value of the manure, but (2) that the amount soluble in alkaline ammonic citrate is; he therefore recommends the latter as the proper reagent for such estimations.—Rectification of a portion of the communication of M. Munk concerning the discovery of lunar variation, by M. L. A. Sédillot. This paper related to the disputed passage of Aboul Wefa.—On the calculus of the luminous phenomena produced in the interior of transparent media having a rapid motion of translation in those cases where the observer partakes of that motion, by M. J. Boussinesq.—On the electric balance and on electrostatic phenomena, by M. P. Volcipelli.—Researches on the electricity produced by mechanical action, by M. L. Joulin.—On the conditions of maximum magnetic effect in galvanomoters and electro-magnets, by M. Raynaud.

DIARY

THURSDAY, JUNE 5.

LINNEAN SOCIETY, at 8.—On the Plants of Kilmanjaro: Dr. Hooker, F.R.S.—On the Lecythidaceæ: John Miers, F.R.S.
CHEMICAL SOCIETY, at 8.—On the Dioxides of Calcium and Strontium: Sir John Courcy, Bart.—On Iodine Monochloride: J. B. Hannay.—A new Ozone Generator will be exhibited by Mr. T. Wills.
ROYAL INSTITUTION, at 3.—Light: Prof. Tyndall.

FRIDAY, JUNE 6.

ROYAL INSTITUTION, at 9.—Lecture: Dr. Odling.
GEOLOGISTS' ASSOCIATION, at 8.—Ammonite Zones in the Upper Chalk of Margate, Kent: F. A. Bedwell.
ARCHÆOLOGICAL INSTITUTE, at 4.
GRESHAM LECTURES, at 7.—On Headaches: Dr. E. Symes Thompson.

SATURDAY, JUNE 7.

ROYAL INSTITUTION, at 3.—The Historical Method: John Morley.
GRESHAM LECTURES, at 7.—On Narcotics and Sedatives: Dr. E. Symes Thompson.

MONDAY, JUNE 9.

GEOGRAPHICAL SOCIETY, at 8.30.

TUESDAY, JUNE 10.

PHOTOGRAPHIC SOCIETY, at 8.—On Experiments with three wet processes: Jabez Hughes.—Notes on the Photo-collotype process: Capt. J. Waterhouse.—On some early Photo-engravings: W. H. Fox Talbot, F.R.S.

WEDNESDAY, JUNE 11.

GEOLOGICAL SOCIETY, at 8.—On the Nature and probable Origin of the superficial Deposits in the Valleys and Deserts of Central Persia: W. T. Blanford.—On *Caryophyllia Brodiei*, Milne-Edwards, from the Red Crag: Prof. P. Martin Duncan, F.R.S.—On the Cephalopoda-bed and the Oolite Sands of Dorset and part of Somerset: James Buckman.—*Cetarthrosaurus Walkeri*, Seeley, an Ichthyosaurian from the Cambridge Upper Greensand: H. G. Seeley.
ARCHÆOLOGICAL ASSOCIATION, at 8.
GEOLOGISTS' ASSOCIATION.—Excursion to Brighton.

THURSDAY, JUNE 12.

ROYAL SOCIETY, at 8.30.
SOCIETY OF ANTIQUARIES, at 8.30.
MATHEMATICAL SOCIETY, at 8.—Some general Theorems relating to Vibrations: Hon. J. W. Strutt.—Invariant conditions of three and four concurrence of three Conics: J. J. Walker.—Locus of the point of concourse of tangents to an epicycloid inclined to each other at a constant angle: Prof. Wolstenholme.

JEREMIAH HORROX

I.

IF national glory can ever be connected with a natural phenomenon, the transit of Venus over the sun's disc may be said to bring peculiar distinction to England. It is in a manner inscribed upon one of the most brilliant pages of our naval history; it led to some of the most remarkable discoveries for which mankind is indebted to our geographical enterprise, and made the renown of our most famous navigator. A hundred and thirty years before Cook, the phenomenon itself was, for the first time in human history, accurately observed in a corner of England, by an English youth, self-taught, and provided with few of the appliances of scientific research. Now that the spectacle, so striking in itself, so sublime in the infrequent regularity of its recurrence, so important as the key to numerous astronomical problems, is again attracting the attention of civilised mankind, now that the expanse of ocean from Honolulu to Kerguelen's Land is about to be dotted with watchers from the other side of the earth, the occasion appears favourable for recalling the memory of the original observer, Jeremiah Horrox, curate of Hoole, near Preston, in his day one of the most insignificant of English hamlets.

The little that is known respecting Horrox's family and circumstances at least suffices to reveal the difficulties with which he had to contend. The place of his birth was Toxteth, near Liverpool. We cannot discover that the date usually assigned, 1619, rests on any good authority, while it is rendered improbable by the fact that in this case he must have been matriculated at thirteen, and ordained at twenty. The first letter of his that has been preserved, dated in the summer of 1636, indicates, moreover, a compass of astronomical knowledge, as well as a general maturity of mind, hardly conceivable in a youth of seventeen; while his references to the discouragements which, previous to his acquaintance with his sympathising correspondent, had almost induced him to renounce astronomical study, bespeak a more protracted period of investigation than would have been possible in such early years. The date 1616, though unauthenticated by any external testimony, may very well be correct. Notwithstanding a doubtful report which traces his family to Scotland, his thoroughly Lancastrian patronymic denotes a local origin. His father's profession is unknown; we suspect him to have been a schoolmaster. The family dwelling is usually identified with a house pulled down a few years since to make room for the railway station. The family was numerous, and although it cannot have been indigent, Jeremiah's matriculation as a sizar at Cambridge, and short stay at the University, prove that it was not rich. His entrance at Emmanuel College, then a stronghold of Puritanism, is conclusive as to the auspices which presided over his bringing-up. This matriculation took place on July 5, 1632; he certainly left the university without a degree, and the fact of his first-recorded astronomical observation, June 7, 1635, having been made at Toxteth, is an almost certain testimony of his recession having taken place before that date. Want of means, and the necessity for contributing to the support of his family, are the only assignable reasons for a step which must have thrown the young student on his own resources, as regarded books, instruments, and intellectual companionship. The first glimpse we obtain of him is from the above-mentioned letter to Crabtree, dated June 21, 1636. From this and subsequent letters we gather that he has been for at least a year an observer of the heavens; that his circumstances are narrow, and prevent him from obtaining the books and instruments he desires; some, however, of the books he incidentally mentions must have been expensive, and can hardly have been procured by him elsewhere than at Cambridge. A list of these in his own handwriting is preserved, and has been noticed by Prof. De Morgan, who ("Companion to the Almanac" 1837) points out that not one was the work of an English mathematician, or printed in this country. It further appears that his time was much engrossed by other pursuits, which no doubt bore reference to his preparation for orders, and to his exertions to support himself in the interim. He was, in all probability, engaged in tuition, to which land-surveying, or some similar occupation, may have been added. Thus three years passed by, at the end of which time we find him curate of Hoole, a village about five miles to the south of Preston, the church of which was at that period a chapel of ease to the adjoining parish of Croston. The patron was Sir Robert Thorall, the incumbent the Rev. James Hyatt. Horrox may be assumed to have been recommended to the latter by their common Puritanism, Mr. Hyatt having been one of the ousted ministers of 1662. He did not, however, retain his curacy much above a year; the cause of his resignation is unknown.

It is now time to treat more specifically of Horrox's correspondence with Crabtree, the source of almost all our information respecting him. Crabtree, a clothier of Broughton, near Manchester, was one of a small band of worthies by whom astronomy was cultivated in the northern counties in those days, some particulars respecting whom will be found in the notes to Sherburne's translation of Manilius. These letters survive in the Latin version of Prof. Wallis, who naturally omitted whatever had no immediate bearing on science. A re-examination of the originals, should these still be extant in the Bodleian Library or elsewhere, might probably result in the retrieval of some interesting biographical particulars. As it is, we obtain many glimpses of the scientific circumstances of the day. Errors were inevitable in the comparative infancy of astronomical science, and the mistakes of the master were naturally a snare to the pupil. Horrox was for a time not only misled, but induced to distrust the accuracy of his own observations by their incompatibility with those of Lansbergius. Crabtree opened his eyes to the errors of the latter, and thus indirectly rendered him the still higher service of leading him to recognise the greatness of Kepler, which Lansbergius had disparaged. His study of Kepler led, as we shall see, to his own great discovery: before entering upon this, however, it will be convenient to dispatch the minor matters of scientific interest contained in the correspondence. It is curious to learn that Horrox's telescope cost him only 2*s.* 6*d.*, and was nevertheless better than some more expensive ones

which he had had an opportunity of examining. He did not obtain even this modest instrument until May 1638, about a year before Milton viewed the moon through "the optic glass" of "the Tuscan artist":—

> "At evening from the top of Fesole,
> Or from Valdarno, to descry new lands,
> Rivers or mountains in her spotty globe."

The "mute inglorious Miltons" of Toxteth seem not to have been wholly incurious respecting the researches of their fellow villager, who speaks in another letter of having endeavoured to exhibit Venus in her crescent phase to "sundry bystanders," who however were unable to discern the phenomenon owing to their inexperience in the use of the instrument. The possession of a telescope may have stimulated his desire to become acquainted with the writings of its inventor. Four months later we find him possessed of Galileo's dialogue on the "System of the Universe," and anxious to procure his "Nuncius Sidereus," and treatise on the Solar Spots. He had previously speculated upon the exact period of the creation of the world, which he sought to determine by a combination of astronomical and scriptural data; and upon the origin of comets, which he supposed to be emitted from the sun. The phenomena of the planetary aphelion and perihelion had likewise engaged his attention, and elicited remarks which almost seem prophetic of the great discovery of Sir Isaac Newton. In observing the setting sun he had noticed a raggedness of the margin, which he rightly attributed to atmospheric conditions. During the last three months of his life, when unable to bestow time on astronomical research, he commenced an attentive study of the irregularities of the tides, from which he hoped to obtain a demonstration of the rotation of the earth. The Lancashire coast, where the recess of the tide is very considerable, is highly favourable to similar observations.

(*To be continued.*)

CARUS'S HISTORY OF ZOOLOGY

Geschichte der Zoologie bis auf Joh. Müller und Charles Darwin, von J. Victor Carus. Pp. 739. (München, 1872.)

TWO of the most characteristic qualities of the present time are scepticism and sympathy; and by a happy combination of the ability to investigate statements instead of taking them on trust, and the power of realising past states of knowledge and of feeling, a most important advance has been made in history. But the historical method is not confined to what is commonly so called. It has been applied to philology and philosophy, and has reformed both, while even in the physical sciences its importance is now fully recognised. It is true that a science like Zoology, which deals entirely with objective facts, is more independent of history than some others, and its history does not really begin till the seventeenth century. But as part of the history of the human mind, it will always be important to study the sciences of pre-scientific ages, and when we meet with such a master-mind as that of Aristotle, whatever he wrote becomes of the highest interest because it was his.

The work before us, by the son of the late eminent zoologist of the same name,* is one of the series undertaken by command of the late King of Bavaria, and published by a Historical Commission of the Royal Academy of Sciences in Munich. It embraces the history of the whole body of science in Germany, and the volumes which have already appeared have been written by men of high eminence in their several departments.

Fortunately, however, Prof. Carus does not at all confine himself to Germany, so that the present work is an attempt at a complete history of zoology, from the earliest to the present time. It naturally divides itself into two parts, the first treating of what may be called pre-scientific zoology, which is only of general historical interest, the second tracing the development of zoology, as a science of observation and experiment, from its foundation by Ray and Linnæus. These two sections are handled on a very different scale, for the former occupies more than half the book, and is therefore sufficiently minute, while the whole history of modern zoology is compressed into three hundred pages. The consequence is that, while accurate as to facts, the latter part is often little but a list of names and dates.

We shall therefore simply direct the attention of zoologists to the second portion of Prof. Carus's history as convenient and well-arranged for reference, and dwell here on his detailed account of the less known progress made in ancient and mediæval times towards a knowledge of the varieties and structure of animals.

The first chapter treats of the earliest animals known to man, including those domesticated in prehistoric times. The names of the Ox, Sheep, Goat, Pig, Dog, Horse, and Goose, occur in allied forms in most of the Indo-European languages, and their bones are found among the dust-heaps of the earliest race of men known. The Cat (αἴλουρος), though domesticated in Egypt, was not a household animal till much later in Western Europe: the "cat" of the Greeks and Romans (γαλῆ) being almost certainly the whitebreasted beech-marten (*Martes foina*) a conclusion learnedly and perspicuously established by Prof. Rolleston in a paper published in the *Journal of Anatomy and Physiology*, for November 1867. But the Flea and the Louse appear to have been familiar from the earliest times, and Mice, Flies, and Worms are also among the first named by man. To the same primitive group belong the Bear, the Beaver, which lived in English rivers up to comparatively recent times, and the Wolf and Fox, the names of which (*vulpes*, Wolf) have evidently been confounded.

After a short account of the part taken by animals in early mythology and in the fables common to the Indo-European nations—a chapter which might have been with advantage enlarged from the pages of Grimm, Dasent, and Link—our author enumerates the domestic animals known in classical times, which include, beside those already mentioned, the Camel (confounded with the elephant during the Middle ages), the common Fowl (ὄρνις περσική Aristoph., Av. 485), which was introduced from the East between the date of Homer and Hesiod and that of Æschylus, the Chenalopex, probably identical with our sheldrake (*Tadorna vulpanser*), pigeons of various breeds, and birds of prey which were used for hawking. The list of wild animals was greatly increased by the games of the Roman circus, and many, like the Hippopotamus, Rhinoceros, and Giraffe were better

* The accomplished author himself is now lecturing in Edinburgh as Prof. W. Thomson's substitute.

known under the Empire than they have been until very recent times. Pliny mentions the occurrence of the Platinista in the Ganges, but no notice of the Hyrax, a form so familiar to the Hebrews, is to be found in Greek or Roman authors.

The next sections are occupied by a tolerably full account of the knowledge of anatomy and physiology possessed by Aristotle, and by his successors, Herophilus and Erasistratus, and of the attempts made towards a classification of the animal kingdom. The groups recognised by the first, and perhaps the greatest, of naturalists, are surprisingly near to what are now accepted. 1. Viviparous quadrupeds, clothed with hair (ζωοτόκα τετράποδα)—Mammalia, exclusive of Cetacea. 2. Birds (ὄρνιθες) exclusive of bats. 3. Oviparous quadrupeds, inclusive of snakes and frogs. 4. Cetacea (κήτη), with teats and milk (Hist. An., iii. 99). 5. Fishes (ἰχθύες). Those with (red) blood are distinguished from the remaining "bloodless" classes. 6. The Cephalopodous mollusks (μαλάκια). 7. The testaceous mollusks, including ascidians, cirripedia and echinidæ (ὀστρακόδερμα). 8. Malacostraca—Crustacea. 9. Insecta (ἔντομα) including all air-breathing Arthropoda. Lastly, Starfishes, Sponges, and some other groups, are characterised as partaking of the nature of plants (Zoophyta).

On the whole, Aristotle's zoology is less imperfect than his anatomy. In spite of Prof. Carus's opinion, the well-known passage (Hist. An. i. 39) clearly states what is repeated in two other passages, that the back of the skull is empty, and his views of the position and functions of the heart, lungs, and nerves are scarcely more scientific than Plato's notions of hepatic triangles. Indeed it is difficult to believe that Aristotle can ever have completely dissected a single mammal. The digestive and reproductive systems he understood much better. But beside his wonderful industry in collecting facts, the acuteness and power of generalisation displayed by Aristotle in other branches of science are not wanting in natural history. Thus he remarks that insects with horny wings have no sting. "I have never seen an animal with solid hoofs and two horns." When horns are present there are no canine teeth. Quadrupeds which bring forth their young alive are clothed with hair, those which lay eggs, with scales. Insects with four wings have the sting behind, those with two, in front. Nor is it the least proof of Aristotle's greatness that he gave an impetus to biological science which produced the Alexandrian school of anatomy, and only ended at the beginning of the third century of our era with the death of Galen.

The contributions of Roman authors to zoology, such as those buried in the huge mass of crude and chiefly worthless material which Pliny called natural history, only mark the decay of the science. During the subsequent dark ages (the darkness of which is probably for the most part subjective) the most remarkable work on zoology is the famous "Physiologus," also called the "Bestiarius Theobaldi," of uncertain authorship and date, but known over the whole of Christendom from the eighth to the thirteenth century by translations into Syriac, Armenian, Arabic, Ethiopic, German, English, Icelandic, and French. The Greek text is probably the original, from which the Latin was taken. This long-forgotten book, like Pliny's, includes accounts of plants, stones, and other natural objects, and describes among more common-place animals, mermaids, unicorns, and onocentaurs. There are mentioned, of quadrupeds, the antelope (perhaps the Urus), beaver, elephant, hyæna, monkey, and lion, beside common European species; thirteen species of birds, including the ostrich; of reptiles, several kinds of lizards, and serpents, but only one invertebrate animal, the ant. The original plan appears to have included only the animals mentioned in the Bible, and the chief object of the book is to draw moral lessons from the habits of the creatures described. The "Physiologus," while of great historical interest, is, of course, devoid of even relative scientific value.

Passing over the Arabian naturalists, who added little original, we come to the three writers who represent the science of the Middle Ages when the writings of Aristotle became generally known and the systems of scholastic philosophy were founded—Thomas of Cantimpré, Albertus Magnus, bishop of Ratisbon, and Vincent of Beauvais. They were all Dominicans, and all belong to the thirteenth century, that remarkable era of revolution in philosophy, politics, and art. At this time knowledge of foreign animals was greatly increased by the travels of Marco Polo (1275–1292), who described the wild horses, musk deer, and yaks of Tartary, the camels and asses of Persia, and the rhinoceroses, elephants and tigers of India.

Museums only began to be formed in the sixteenth century when the discovery of America brought to light so many new animals and plants; but for a long time they were what museums still too often are, mere lumber rooms of "Dinge gantz seltzam und fremd'," as Duke Albert of Prussia wrote in 1559. All the earliest anatomical preparations, including the celebrated dissections of Harvey still preserved in the College of Physicians, are dry.

The *Lucidarius*, a medley of stories about animals, which represents in the Renaissance what the Physiologus does in the Middle Ages, appeared in 1479, and like the latter was translated into all the European languages.

The earliest attempt at a System of Zoology was by Wotton in his *Differentiis Animalium*, published at London in 1550. It is little more than a reproduction of the doctrine of Aristotle. Conrad Gesner's *Historia Animalium* appeared in 1551. Like Wotton, he was a physician, and practised in Switzerland and South Germany. His work is chiefly remarkable for its illustrations, one of which, the figure of the Rhinoceros, was drawn by Albert Dürer. Passing over the names of Aldrovandi (1522-1603), Johnston (1603-1675), and Sperling (1603-1661), the next important work on zoology was Bockart's *Hierozoicon*, published in 1663. This work of the learned Norman Huguenot has been a quarry which succeeding biblical commentators have continually used, but its value is almost entirely literary: indeed it was written rather as a contribution to hermeneutics than to natural science. The figures in a work of Clusius, "Exotica," which belongs to the early part of the seventeenth century, show by those of the sloth, the manatee, the armadillo, humming-bird, cassowary, dodo, penguin, and molucca crab, how much the discoveries made in America, Madagascar, and New Holland, were increasing the list of known animals.

During the first half of the seventeenth century there also appeared the earliest monographs. Thus Nicholas Tulp, the anatomical lecturer in Rembrandt's famous painting at the Hague, gives a description and an admirable engraving on copper of what he calls an "orang-outang," evidently a chimpanzee from Africa; and in the same *Observationes Medicæ* (1641) figures a narwhal as "Unicornis marinus." The *Libellus de Canibus Britannicis* (dedicated to Gesner), of our countryman John Kay (Caius) was earlier than Tulp's papers. It was followed by monographs on the elephant by Lipsius and Caspar Horn, on the stag, with an account of its dissection, by Agricola, of the hippopotamus, from a specimen sent in brine from Damietta to Rome, by Columna, and of fishes in general by Salviani and Rondelet. In 1634 was published at London *Insectorum theatrum*, avowedly founded on the words of Wotton and Gesner, and on a compilation from both which had been begun by Thomas Penn, and interrupted by his death; the next editor was Thomas Mouffet, but he also died several years before it was published. This is a noble monograph, with woodcuts so accurate and characteristic as to compare with the best productions of modern skill. It is also remarkable for containing a full and correct account of the *Acarus scabiei*, which was afterwards so long forgotten. Beside insects (in the Linnæan sense of the word) it describes worms of various kinds, and among them what is apparently a *Bothriocephalus latus*. This species is still more distinctly figured by Tulpius (Obs. Med. tab. vii), but by some strange error it is represented with two heads. Spigelius (*de lumbrico lato*) gravely discusses whether it is an animal at all.

Meantime anatomy and physiology were making rapid progress. Vesalius (1514-1564), the father of modern anatomy, and his contemporary Eustachius, who ventured to oppose his own dissections to the authority of Galen, Fallopius, and his successor at Padua, Fabricius, and the still more illustrious pupil of Fabricius, William Harvey, form a succession of almost unequalled eminence. The dissections of our countryman Thomas Willis (1621-1675) were not confined to human subjects, and the earliest microscopical observations, by Malpighi, Leeuwenhoek, and Hooke, were also to a large extent zoological. After the middle of the seventeenth century the three most illustrious scientific societies were founded, the *Academia Naturæ Curiosorum* (1652) incorporated as the "Leopoldinisch-Carolinische Academie" in 1677, the Royal Society in 1662, and the Académie des Sciences four years later. In 1667 Ray was elected a Fellow of the Royal Society, and began the series of papers which mark the first steps of scientific zoology, and surely prepared the way for his greater successor Linnæus. P. H. PYE-SMITH

OUR BOOK SHELF

Lehrbuch der Physik. Von Dr. Paul Reis, Zweite Lieferung, Leipzig. (Quandt and Bäudel, 1873.)

THE second part of this useful handbook of physics opens with the explanation of Mariotte's Law and the various applications of atmospheric pressure. The next division is devoted to the study of wave motion, which is discussed far more fully than in the ordinary run of scientific text-books. This leads on to acoustics, and we are at once plunged rather abruptly into the subject of musical intervals. The theory of consonance, the cause of the intensity of sound and its mode of propagation make up the novel arrangement of this chapter. Optics occupies the sixth division, and is carefully treated. Especially noteworthy is the chapter on the theory of the absorption and dispersion of light, in which there is an excellent account of spectrum analysis. The part before us breaks off in the discussion of physiological optics, where Helmholtz's researches are in part developed. It is a pity that the engravings are not equal to those generally found in continental text-books.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Jacamar in Britain

I SEE, in your review of Mr. Cordeaux's "Birds of the Humber District," mention of a Jacamar—I presume a Galbula—having been shot by a keeper named S. Fox, near Gainsborough, in 1849. You and the author, Mr. Cordeaux, naturally remark on the "extraordinary" puzzle of the fact.

As one who has often seen the Jacamar in its own tropic forests, and watched its flight and its feeding, I must be allowed to suspect some mistake, unless the most "startling"—in every sense of the word—evidence of the authenticity of the specimen is given.

Ready to believe everything, in such a world of wonders, I might have believed in a Jacamar being blown to south-west Cornwall, Ireland, or Scotland. But in the eastern counties—"Qu'allait il faire dans ce galere là?"

Harrow, June 6 C. KINGSLEY

The Use of Wires in Correcting Echo

[The following letter has been forwarded to us by Mr. J. J. Murphy]:—

Palace, Cork, May 30, 1873

My Dear Mr. Murphy,

Having seen in the newspapers some notices of the use of wires for correcting the echo by breaking the waves of sound in churches and public buildings, we were anxious to try the experiment in the cathedral of St. Fin Barre, Cork, the nave of which is of great height, between 60 and 70 feet, and narrow in proportion to its height. We were unable to obtain any reliable information as to the placing of the wires, so that what we did was very much in the way of experiment. I should state that the desks for the officiating clergy and the choir are placed at the intersection of the transepts, nave, and chancel, so that this may be regarded as the point from which the sound starts. The organ is placed in a gallery at the west end, and the organist seated in this gallery has always heard much more distinctly than the people sitting about two-thirds down the nave, particularly those close to the pillars; but the echo seemed to render the sound indistinct, more especially in the transepts, the north and south walls of which presented a large flat surface, and appeared to us to be probably the source of the echo.

At first we tried the wires strained at a considerable height, the level of the triforium, but they produced comparatively little effect; we then strained a double course of wire at about a height of 12 or 15 feet round the large piers of the central tower, so as to encompass the choir, and other wires completely across the nave and side aisles, and the effect was certainly very good. There was a greater distinctness of sound throughout the building. Our organist, who is a very accomplished musician, did not know that the wires were put up, and remarked to me one day after service that he did not know what it was, but that everything seemed to him in better tune.

This encouraged us to make further experiments. We then strained three wires completely across from the south wall of the south transept to the north wall of the north transept, so as to pass over the heads of the choir, but the effect was quite too great, it seemed to kill the sound, every sound seemed to stop at once, all resonance was gone. These wires we had at once to take down, and I should add that, as regards the organist, the wires over the heads of the choir seemed to produce a much greater effect than those directly between the choir and his

seat; it appeared to him as if he had a bad cold and could not hear distinctly.

These wires appeared to prevent the voices rising and filling the cathedral. It seems very difficult to determine where to place the wires so as to produce a really good effect; but that they have a very great effect far beyond what one would have supposed, *a priori*, is admitted by all who have taken an interest in the matter here. Several members of the congregation have remarked that they heard better in the cathedral now, without knowing the cause. We have used very thin wire; a stranger would not perceive it unless his attention were called to it. We hope to make some further experiments especially with regard to the transepts of the cathedral.

The inexpensive nature of the experiment and the important result likely to be obtained make this a matter of great importance, independently of the great interest it possesses in a scientific point of view.

I may add that when in Dublin I attended Divine service in St. Andrew's Church, and having officiated in the church at different times I am well aware of the difficulty of filling it in consequence of the echo, but the use of the wires appeared to have made a very great difference, as I heard most distinctly. It seemed to me, however, that a far greater number were used, than my experience in Cork would have led me to suppose were necessary.

I hope this subject will receive the attention which it deserves.

J. J. Murphy, Esq. ROBERT S. GREGG

Fertilisation of the Wild Pansy

THERE are two points in the structure of the heartsease (*Viola tricolor*) which are not mentioned in Mr. Bennett's interesting article on its fertilisation, but which, I think, deserve notice.* The first of these is the lip of the stigma, which closes the entrance to the spur and must be pushed back by an insect trying to reach the nectary, thereby bending down the head of the stigma, so as to sweep any pollen that may be adhering to those parts of the insect which come into contact with it into its receptacle; while, in withdrawing, the insect necessarily presses against the lower side of the lip, and raises up the whole stigma, thus rendering self-impregnation impossible, or at least highly improbable. Modifications of the same contrivance may be seen in many other flowers, *e.g. Pinguicula*, *Iris*, &c.; it reaches, perhaps, its greatest perfection in *Mimulus* and *Bignonia*,† where, to the usual mechanical disposition of the parts, there is added irritability of the stigmatic lobes, which close together spontaneously when touched, expanding again after a while, if not already pollenated.‡

The second point to which I have alluded is the close, hairy lining of the fore part of the spur, forming a narrow groove at the base of the lowest petal.§ This groove generally contains a quantity of pollen that has fallen from the overhanging anthers. There is also a small tuft of hairs at the base of each of the lateral petals, arching over the essential organs, and forcing an insect to approach the nectary from below. These lateral tufts are present, I believe, in all the violets, but *V. tricolor* (including therein several sub-species) is the only British species which has the spur lined with hairs, as well as the only one not known to bear self-fertile cleistogenous flowers.

Although the flowers of the wild heartsease are quite scentless to our blunt organs, does it follow that they are necessarily so to an insect's far more delicate sense?* Some of the cultivated pansies are very sweet, and I am not aware that this quality has ever been made an object for selection by florists. These large garden pansies are much frequented by *Bombus muscorum*, which may be watched while performing the act of pollenation, as described by Prof. Hildebrand. W. E. HART

Kilderry, Co. Donegal

P.S.—Mr. Farrer, in writing of *Lotus corniculatus* (NATURE, vol. vi. p. 499), says:— "Five of the stamens, viz., those of the inner whorl, are shorter than the others, and their filaments are dilated at the top." Here Mr. Farrer's usually accurate pen seems somehow to have made a slip. It is the long outer stamens, those opposite the calyx-teeth, which have their filaments thus curiously modified for the purpose there explained.

* Both these points have already been described by Prof. Hildebrand ("Die Geschlechter-Vertheilung bei den Pflanzen," p. 53). Unfortunately, I have not the works of Sprengel and Hermann Müller to refer to.

† I have had no opportunity of examining the latter, but from the published descriptions it seems to correspond in its main features with *Mimulus*, of the process of fertilisation of which a full account has been given by Mr. F. E. Kitchener in the *Journal of Botany* for April.

‡ When it becomes necessary to introduce a new word into the language it is always well to select the most appropriate that offers itself. Some time ago Mr. A. W. Bennett wrote to the *Journal of Botany* (vol. ix. p. 112), asking for suggestions for a better rendering of the German word *Bestäubung* than "be-pollenment" or "pollenizatioo." I afterwards (*Journ. Bot.*, vol. x. p. 25) proposed the term "pollenation," which has since been accepted by Mr. Bennett. He, however, continues to use the verb to "pollenize." Now, if I might be allowed the space, I should like to state my reasons for objecting to this expression—(1) The root *pollen* is Latin, while the termination ιζω is Greek. Of course, this objection is over-ruled by common usage, and by itself would go for nothing. (2) The word "pollenize" does not in its structure convey the idea intended. *Bestäuben* means to "sprinkle with dust," to "dust with pollen." The termination "ize," on the other hand, gives the signification of change or conversion; thus to "pollenize" would naturally meao to "pulverize," to "turn to flour or pollen," and might be correctly applied to the processes going on in the substance of the anthers, but not, without violence to grammar, to the application of pollen to the stigma. Numerous precedents might be cited for the use of the word "pollen," unaltered, as a verb, from which would be derivable either "pollenation" or "pollenment," but this would be at the risk of offence to ears scientific. The same objection would apply with still greater force to the word "be-pollen." "Empollen" is more euphonious, but would convey a slightly different meaning. On the whole, the word that I have used in the text is the best that I can think of. Perhaps some of your more classical readers might give us their opinions.

§ Morphologically speaking, this is the uppermost petal, which, by the bending of the peduncle and consequent inversion of the flower, is made to assume the position best fitted to afford a convenient landing-place for insects.

* The flowers of *V. palustris*, which are nearly unicolorous with a few dark lines pointing to the nectary, are apparently scentless; but after standing for a short time in water in a warm room, they become quite sweet.

Fertilisation of Orchids

MR. DARWIN, in his "Fertilisation of Orchids," speaks of a Madagascar orchid (*Angræcum sesquipedale*) with nectaries 11½ inches long, and supposes that these plants must be fertilised by the efforts of huge moths, with probosces capable of such expansion, to obtain the last drops of the nectar which is secreted in the lower part of these whip-like nectaries. Can any of your readers tell me whether moths of such a size are known to inhabit Madagascar? They would probably be Sphingidæ of some kind, as no other moths would combine sufficient size and length of proboscis. W. A. FORBES

Culverlea, Winchester, June 2

Ground Ivy

I HAVE this spring found, in many different places, specimens of ground ivy, having flowers with undeveloped stamens. They seem generally, though not always, to be on different plants from those bearing perfect flowers, and below the average in size, the tube being more slender. Also, in nearly all my specimens, the stigmas diverge in a more or less horizontal direction (across the flower) instead of remaining open in the usual vertical one. Is this second form of the flower common? and if so, may not the greater tendency to horizontal divergence compensate for the want of stamens, by bringing the stigmas into the position most favourable for receiving from an insect any pollen which a previous visit to a perfect flower may have left on its head or back? S. S. D.

Hail Storm

DURING the passage across us this afternoon of a thunderstorm moving at so great a distance above the earth that the thunder was very feeble and the lightning very faint, we had a great hail storm, which commenced with conical-shaped opaque stones of the size of peas, at $4^h\ 27^m$ (only lasting one minute), beginning again at $4^h\ 29^m$ with circular transparent stones having a small opaque nucleus (again only lasting one minute), followed at $4^h\ 33^m$ with flattened stones of the form of common acid drops, transparent, except a thin opaque envelope (which soon melted), and having *externally* in the centre a small rugged piece of ice. The size varied from two to three inches in circumference, and the force with which they fell cut off the leaves from the trees and broke 200 panes of glass in my greenhouses. These stones continued to fall for seven minutes with very heavy rain.

Twelve hailstones were gathered after the storm was over, and on being melted yielded 0·060 inch of water when measured in the glass of an eight-inch gauge, and the amount caught within an eight-inch hoop measured 0·750 of an inch, and this added to the rain, gave 1·430 inches as the amount fallen during the storm. THERMO-ELECTRICITY *

II.

GUIDED by considerations of Dissipation of Energy, I was led some years ago to the hypothesis that specific heat of electricity must be, like thermal and electric resistance, directly proportional to the absolute temperature. If this were the case, the lines in the diagram would be straight for all metals; and parabolas would be the graphic representation not only of electromotive force, but of the Peltier effect, in terms of the temperature of a junction. And I found by actual measurement of curves plotted from experiment, that, within the range of mercury thermometers, the curves of electromotive force for junctions of any two of iron, cadmium, zinc, copper, silver, gold, lead, and some other metals, are parabolas with their axes vertical; the differences from parabolas being in no case greater than the inevitable errors of experiment and the deviation of mercury thermometers from absolute temperature. If, then, the line for any one of these metals be straight within these limits of temperature, so are those of all the others. This makes the tracing of the diagram within these limits a very simple matter indeed. And an easy verification is furnished by the fact that from the parabolas for metals A and B, and A and C, we can draw the lines for B and C, assuming any line for A; and we can then compare the temperature of the intersection of these lines with that of the neutral point of B and C as found directly. Another verification is supplied by the tangents of the angles at which these parabolas cut the axis of abscissæ, for the sum of two of them ought in every case to be equal to the third.

In fact, if we assume, in accordance with what has been said above,

$$\sigma_1 = k_1 t, \quad \sigma_2 = k_2 t,$$

where k_1 and k_2 are constants, Thomson's formulæ give at once

$$\frac{\Pi}{t} = -\int (k_1 - k_2)dt,$$

or

$$\Pi = (k_1 - k_2)(T_{1,2} - t)t$$

where $T_{1,2}$ (the constant of integration) is obviously the temperature of the neutral point.

Also

$$E = J\int \frac{\Pi}{t}\,dt = J(k_1 - k_2)\int (T_{1,2} - t)dt$$

$$= J(k_1 - k_2)(t - t_0)\left(T_{1,2} - \frac{t + t_0}{2}\right)$$

where t_0 is the temperature of the cold junction. This is the parabolic formula already mentioned.

Comparing with the parabola as given by observation we get the values of $k_1 - k_2$ and $T_{1,2}$. Similarly we obtain $k_1 - k_3$ and $T_{1,3}$. Hence we may calculate $k_2 - k_3$, and (by the second equation above) the value of $T_{2,3}$ from the relation

$$(k_1 - k_2)T_{1,2} + (k_2 - k_3)T_{2,3} + (k_3 - k_1)T_{1,3} = 0.$$

Thus we have the means of verification above alluded to—for the equation just written expresses the relation between the tangents of the angles at which the three parabolas cut the axis of abscissæ.

[It is to be remarked that if the circuit consist of one and the same metal, we have

$$k_1 = k_2,\ T = \infty,\ (k_1 - k_2)T = \tau \text{ suppose},$$

whence

$$\Pi = \tau t,$$

which shows that the electric convection of heat may be regarded as an infinitesimal case of Peltier effect between adjacent portions of the same metal at infinitesimally different temperatures.

Also, on the same hypothesis, we have

$$E = J\tau(t - t_0)$$

which seems to accord with the result of some experiments made for me by Mr. Durham, in which the deflection due to the contact of the hot and cold ends of the same wire was shown to be proportional to the difference of temperatures and independent of the actual temperature of either.]

Endeavouring to extend the investigation to temperatures beyond the reach of mercury thermometers, I worked for a long time with a small air-thermometer, of which the principle was suggested to me by Dr. Joule. But this involved very great experimental difficulties, due mainly to chemical action at high temperatures; and, after much unsatisfactory work, I resolved to make one thermo-electric junction play the part of thermometer in observing the indications of another. In fact, an exceedingly elegant result follows at once from the preceding formulæ, if we suppose the specific heat of electricity to be proportional to the absolute temperature in each of four metals, and then draw a curve whose ordinate and abscissa are the simultaneous galvanometric indications of pairs of these metals, with their hot and cold junctions respectively at the same temperatures. For if τ be the difference of absolute temperature of the junctions, we have

$$x = A\tau + B\tau^2$$
$$y = C\tau + D\tau^2$$

where the four constants depend upon the nature of the metals and upon the absolute temperature of the cold junction. These equations give

$$(Dx - By)^2 = (CB - AD)(Cx - Ay)$$

which is the equation of another parabola, also passing through the origin, but with its axis no longer vertical.

A simple proof of this theorem is furnished by the motion of projectiles in vacuo. Suppose a particle to move under gravity, and subject, besides, to another constant force parallel to a given horizontal line—its path would have both ordinate and abscissa parabolic functions of the time. But its path might also be found by compounding into one the two accelerations, and as each of these is constant in direction and magnitude, their resultant will have the same property, and thus the resultant path is a parabola. Tried in this way through ranges of temperature up to a red heat, I found that while some pairs of circuits gave excellent parabolas, others were far from doing so, sometimes in fact giving curves with points of contrary flexure. I was on the point of recurring to the air-thermometer, when I noticed that in nearly every case in which the curve was not a parabola, iron was one of the metals employed; and, by the help of some alloys of platinum, I was enabled to get an idea of the true cause of the anomaly, and afterwards to verify it by an independent method. The cause is this, that while, as Thomson discovered, the specific heat of electricity in iron is *negative* at ordinary temperatures, it becomes *positive* at some temperature near low red heat; and remains positive till near the melting point of iron, where it appears possible, from some of my experiments, that it may again change sign. Thus the line for iron, straight at ordinary temperatures, passes downwards from the first quadrant to the fourth, and thence rises into the first again.

To recur to our analogy, an income represented by the iron line is one which for a number of years steadily diminishes, reaches a minimum, and then steadily increases. If this be associated with a steady expenditure, the fluctuations of capital will depend upon the comparative values of the expenditure and the minimum income. If the expenditure be less than the minimum income, the capital will go on increasing slower and slower to a certain point, then faster and faster; there will be no stationary point, but there will be a point of contrary flexure. If the expenditure be just equal to the minimum income, the point of contrary flexure will be also a stationary point. If the expenditure be greater than the minimum income there will be a maximum of capital, then a point of

* Abstract of the Rede Lecture, concluded from p. 88.

contrary flexure, and then a minimum; the maximum and minimum being the stationary points corresponding to the two occasions on which the expenditure equals the income. The maximum and minimum will obviously be farther apart, and smaller, the larger is the expenditure compared with the minimum income.

The latter part of these statements is well exhibited by the behaviour of circuits of iron, and various alloys of platinum with Iridium, Nickel, and Copper.

[Some of these, involving two, and in one case three, neutral points, were shown.]

In each of these cases there are obviously two neutral points, at least. Now suppose the two junctions raised to the temperatures of these two neutral points respectively, and we have a thermo-electric current maintained *entirely* by the specific heat of electricity, as there is obviously neither absorption nor evolution of heat at either junction. Still further, suppose (as is *very nearly* the case with one of the alloys I have just used) that the specific heat of electricity is *null* in the metal associated with iron, and we have the very remarkable fact of *a current maintained in a circuit, without absorption or evolution of heat at either junction or in one of the metals, but with evolution of heat in one part of the second metal and absorption in another part.* This suggests immediately the idea that iron becomes, as it were, a different metal on being raised above a certain temperature. This may possibly have some connection with the Ferricum and Ferrosum of the chemists; with the change of magnetic properties of iron, and of its electric resistance, at high temperatures. Dr. Russell has kindly enabled me to verify these properties in a specimen of pure iron prepared by Matthiessen. I find similar effects with Nickel at a much lower temperature. The method of control which I employed to satisfy myself that these peculiarities are due to iron and not to the platinum alloys, requires a little explanation. It depends upon the fact that by the help of two metals made into a double arc (wires of the two being stretched side by side, without contact except at the ends) we can explore any portion of the field between the lines for these two metals by simply altering the ratio of the resistances in the two parts of the double arc. Such a complex arrangement gives a line passing through the intersection of the lines of the two constituents, and depending for its position on their relative resistances. I shall not, at this stage of my lecture, trouble you with the formula which gives the line for the double arc in terms of the resistances of the two metals and their lines, but simply show the experiments with the help of a gold and a palladium wire, the one having the specific heat of electricity positive, the other negative; while their neutral point is considerably below the temperature of the room. Between their lines is included the peculiar portion of the iron line, and by making shots at it, as it were, in various directions from the neutral point of gold and palladium, we shall be able to study its bearings.

[Several of these experiments were shown, till finally the gold wire was melted.]

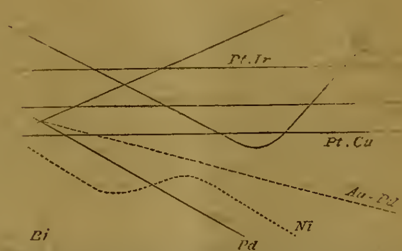
I have here wires of iron, gold, and palladium, bound together at one end, which is to be the hot junction. One end of the galvanometer coil is connected with the free end of the iron wire, the other slides along a long copper wire which connects the free ends of the gold and palladium wires. By sliding it towards either I diminish the resistance of that branch of the double arc and increase that in the other—*i.e.* I give that branch of the double arc the greater importance in the combination.

Throwing the greater part of the resistance into the palladium branch, I find a neutral point at a moderate temperature, but I cannot reach a second without melting the gold. Throw more resistance into the gold, the first neutral point occurs at a higher temperature than before; but a second is attainable. By still further increasing the resistance in the gold the two neutral points gradually approach one another, one rising in temperature the other descending, until at last we reach a maximum-minimum, the result of the confluence of the two points. The line for the double arc is now such as to *touch* the iron line. Still further increase the resistance of the gold, and we find a mere point of inflexion, the galvanometer indications having constantly *risen*, though at a retarded and then accelerated rate, during the heating of the junction.

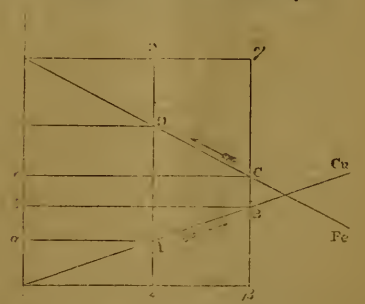
Two of the platinum alloys which I employed with iron seem to give lines almost exactly parallel to the lead line—*i.e.* in them the specific heat of electricity is practically *nil*. When a circuit is formed of these alloys the current therefore depends upon the Peltier effects at the junctions alone, and is sensibly proportional to the difference of their absolute temperatures, thus furnishing a very convenient thermometer for the approximate estimation of high temperatures. I am at present engaged in drawing the thermo-electric diagram in terms of temperatures as given by this combination, and the reduction to absolute temperatures will finally be effected by a comparison of this temporary but very convenient standard with an air-thermometer.

P. G. TAIT

NOTE.—The following rude sketch of a part of the thermo-electric diagram will perhaps render some of the preceding remarks more intelligible. It is drawn to illustrate qualitative effects alone.



The following diagram exhibits the amount of the Thomson and Peltier effects, and of the electromotive force, in a copper-iron circuit, the temperatures of both junctions being under that of the neutral point.



Peltier effect at cold junction	=	Area $ADda$	(heating)
,, ,, hot ,,	=	,, $BCcb$	(cooling)
Thomson effect in Copper	=	,, $AB\beta a$	,,
,, ,, Iron	=	,, $DC\gamma\delta$	,,
Electromotive Force	=	,, $ABCD$	

The arrows show the direction of the current; and Euclid's proposition as to parallelograms about the diagonal of a parallelogram shows at once the application of the first law of Thermodynamics to the figure, as the Electromotive force together with the Peltier effect at the cold junction obviously amount to the sum of the two Thomson effects and the Peltier effect at the hot junction.

Also, if we suppose the lines A D, B C, to be very close to one another, since we have always $AD = \frac{\Pi}{t}$ we get $(BC - AD)t = t\delta\left(\frac{\Pi}{t}\right) = -(\sigma_1 - \sigma_2)\delta t$, whose application to the second law is obvious. The reader may easily construct for himself diagrams for other cases of relation of the temperatures of the junctions to that of the neutral point.

Thomson's original paper will be found in the *Transactions of the Royal Society of Edinburgh*, and farther details of my experimental work in recent numbers of the *Proceedings* of the same society. I may avail myself of this opportunity of asking assistance from men of science in procuring wires or foil of the more infusible metals, such as Cobalt, Chromium, Tungsten, &c.

P. G. T.

*THE LAW OF STORMS DEVELOPED**

I.

METEOROLOGISTS tell us that their science is as old as Aristotle. If we should judge by its progress up to the middle of the present century, its antiquity furnishes little to boast of; for, in the long lapse of centuries, it must have proved an incorrigibly dull scholar. Within the past few years, however, it has greatly improved, and, especially since it became identified with the popular and important systems of storm-warnings and weather-forecasts, it has been rapidly developed. This is peculiarly the case in America, and it is not wonderful, when we consider the comprehensive observations of our meteorological bureau, and the many beautiful phenomena which its publications disclose.

If Vasco Nunez, the discoverer of the great South Sea, was so awed by the grandeur and expanse of its waters, as seen with the naked eye, how much more may we be impressed as telegraphic meteorology enables us to discover, at a glance, the tossings and undulations of the aërial ocean over the larger part of the hemisphere!

It is to some of the deductions, that may be justly made from the extensive and synchronous observations of the modern weather-systems, as they bear upon those weather-problems, which, from time immemorial, have interested mankind, that we now ask attention.

Until the year 1821, "the law of storms," simple as it is, was unknown to the most profound meteorologists and expert seamen of the world. It was then first discovered and announced by Mr. William C. Redfield, of New York, and established by the labours of that great mind, against the constant perversions and opposition of the scientific empirics of his day. It can be easily comprehended in its great outlines, and as far as our present purposes require. It assumes nothing, supposes nothing; but, from thousands of actual and actually recorded observations, presents the phenomena of spiral currents of air seeking a common centre of depression, and, in the attempt to find that centre, acquiring a vorticose or rotatory motion. The direction of this rotation Mr. Redfield found to be uniformly, in our hemisphere, contrary to that of the hands of a watch, with its face turned upward; and, in the Southern Hemisphere, the rotation is with those hands, or with the sun in its diurnal round. It is easy to see that, if the atmospheric column, resting over any given area of the earth's surface, should, from any cause, be suddenly diminished, or its pressure and intensity be reduced, the gaseous fluid would rush in from all surrounding regions to restore the disturbed equilibrium; and if the earth was not whirling around on its axis, every particle of the centre-seeking air would endeavour to move on the shortest, or the straight line. It is known, from the principles of mechanics, that this endeavour can never strictly be executed, because the axial rotation of the globe incessantly so acts as to throw every body, while in motion, in our hemisphere, to the *right* of the line on which it is moving, no matter whether that line be from east to west, north to south, or at any conceivable angle with the meridians or the equator. Obeying, in part, this tangential impulse, every particle of wind must take up a resultant motion. If it begins to blow toward the depressed centre of the storm as a north wind, it trends to the west, and is felt as a northeaster; if it begins as a south wind, it diverges as a southwester; if as an east wind, it becomes a southeaster; and, if as a west wind, it soon changes into the boreal northwest wind.

It has often been asked whether the storms of our latitudes attain the immense size formerly attributed to them; and many eminent writers have denied the possibility of their reaching a diameter of more than two or three hundred miles. Mr. J. K. Laughton, in his recently-published "Physical Geography," would have us believe that cyclones "do not attain the enormous magnitudes which have been assigned them." But this opinion rests merely upon conjecture, not yet upon a correct physical theory.

It is a well-known fact that the monsoons generated on the central plateau north of the Himalaya Mountains, and the whole system of Asiatic wet monsoons, may be regarded as an immense and prolonged cyclone; extend their "backing" influence into the Indian Ocean, and reach far to the south, through more than forty degrees of latitude (a radius of 2,500 geographical miles), and from the 60th to the 140th meridian of east longitude, far out into the Pacific, beyond the Bonin and Ladrone Islands, southeast of Japan. The whole system of wet monsoons may also be justly regarded as a grand cyclone, whose centre is stationary over the heated plains of Central Asia, whose intro-moving winds, bearing the evaporations of the Asiatic seas and oceans, feed it with meteoric fuel for six months in the year, and whose periphery may be regarded as embracing nearly one-third of the entire eastern hemisphere. Analogy, therefore, warrants the idea of a great cyclone. But, apart from all this, actual observations in different parts of the globe prove the frequency of storms of enormous magnitude. Thus, in the celebrated Gulf-stream storm of 1839, as Sir David Brewster long ago pointed out, several staunch merchantmen were foundering off the coast of Georgia, near Savannah, in the very heart of the gale, at the same hour that the winds in its north-west quadrant were taking the roofs off houses in New York and Boston, more than 800 miles distant—clearly revealing a cyclone whose formation was symmetrical, and whose diameter must have been nearly 1,300 miles. But, not to go back to old data, the West-Indian storm of August 18, 1871, before its centre had moved north of Florida, had begun to draw upon the regions of high barometer in the Northern States, had exerted its influence as far north as New London, Connecticut, and gave us the north-easterly cyclonic winds in the north-west quadrant of the whirl, on the entire Atlantic coast. The more furious cyclone of August 24, 1871, discovered to be then south-east of Florida, and telegraphically fore-announced as likely to endanger the coasts of the Southern

* From the *Popular Science Monthly*. Communicated by the author, Prof. Thompson B. Maury, of the Signal Office, Washington.

States in less than forty-eight hours, appeared on the 26th in full force in Northern Florida, but not until some eight or ten hours after it had set the atmosphere all around it (as far north as Boston) in cyclonic motion, and had caused the storm-cloud to spread itself over the entire region of the United States on the eastern slopes of the Alleghanies, and as far westward as Knoxville, Tennessee. It is no uncommon thing, as Redfield, Espy, Henry, Loomis, and others, long ago showed, for an area of depression on the upper lakes to make itself simultaneously felt as far south as the Gulf of Mexico, and as far east as New England.

If it fell within the scope of the design of this paper to consider the final cause of storms, it would be easy to show that, unless the law of storms ordained a large area, and a far extended path for the meteor, in some degree commensurate with the area of our immense continent, the meteor could not fulfil its office in the terrestrial economy—an office which, apparently, imposes upon it the task of gathering to its centre, through the agency of its intro-moving winds, the idle and inappreciable moisture scattered over the surface of the earth, condensing it into rain and snow, and diffusing it in these forms over immense districts of country.

It is of incalculable importance to observe, and carefully digest the fact, that when a storm-centre or area of low barometer is once formed, it is the nucleus for a vast aggregation and marshalling of meteoric forces. No matter how small at first, under favourable atmospheric conditions, the *courant ascendant* is formed, condensation aloft sets in, and the precipitation only serves to add "fuel to the flame" of the cyclonic engine. This process widens in geographical area, and after a few hours have elapsed, the storm may so develop as to cover a continent with its portentous canopy of cloud, while simultaneously strewing an ocean with wrecks, and throwing out in the upper sky, more than a thousand miles in its front, the fine filaments of the premonitory cirrus and cirronus.

In close connection with the size and magnitude of cyclones must be considered the distance over which they pass from their initial point. Much has been said on this part of our subject, and not a few writers have accepted the doctrine of Admiral Fitzroy, that they progress over but comparatively short distances. For such a view, however, it is impossible to find, either in the nature or physical office of the cyclone, any support whatever. The storm once engendered, no matter in what part of the world, may be stationary or progressive. There are well-authenticated instances of almost stationary cyclones and almost stationary typhoons, of which latter will be remembered the famous gale of the ship *Charles Heddle*—an Indiaman, carried round and round the storm-centre for five days—which progressed not more than 90 miles a day. Indeed we may, as has been said, regard every wet-monsoon region as a stationary and semi-perennial cyclone. Such a meteor has been shown to resemble an eddy moving in the current of a rapid river. The latter may be large or small, while it does not determine, but is determined by, the course of the on-flowing stream. It is true the centre of an eddy or water-hollow may soon be filled up and the whirl disappear; but it is because the depression is not maintained. If the depression could be maintained, it is easy to see that the eddy would continue, and pursue its way, as long as the current in which it is embodied continues to flow; it might be through the length of an Amazon or a Mississippi River. In the case of a cyclonic eddy or whirl, we know the atmospheric depression is maintained as long as the centre moves in a region sufficiently supplied with aqueous vapour to feed it. It is a physical impossibility, as has been often shown, that any storm, however vast or however violent, can prolong its advance or sustain its fury over a dry and desiccated surface. The most extended typhoons of the East, upon entering the dry and rainless continental regions, dwindle into the well-known and diminutive dust-whirlwind, such as Sir S. W. Baker describes as witnessed in Nubia, and as here illustrated, from the admirable pages of Mr. Buchan. The Sahara is a more formidable barrier to the passage of a storm than the majestic mountain wall of the Alps, and the simoom is, notwithstanding the stories of travellers and the legend of swallowing up the army of Cambyses on the African desert, a wasted and worn out cyclone. In his "Desert World," Mangin, compiling the more accurate observations of the phenomenon, says: "Whatever prevails over any considerable area, and beyond its limits the atmosphere remains serene and calm; the phenomenon is of brief duration, the atmospheric equilibrium is speedily restored; the heavens recover their serenity; the atmosphere grows clear, and the sand-columns, falling in upon themselves, form a number of little hills or cones, apparently constructed with great care, like those mimic edifices of sand made by children in their pastime." The same writer also mentions a severe simoom which was "over in a couple of hours."

Embedded in the great aërial currents, however, and supplied with abundance of moisture, there is nothing to arrest either the rotatory or progressive movements of the storm. Like the drift-bottles cast upon the current of the ocean, and found after months to have been carried thousands of miles, from the equatorial to the polar parallels, there is every reason to suppose the tropic-cradled gale, and the minor storms also, are borne in the great atmospheric currents through quite as great distances. There is an authentic and well-attested account of a Japanese junk, lost or deserted off Osaka, drifting through the immense arc of the Kuro Siwo's recurvation, and encountered (in latitude 37°, by the brig *Forrester*, March 24, 1815) off the coast of California. That tiny craft must have followed in the bands of westerly winds and warm waters for seventeen months. Why, upon theoretical grounds, should we reject the hypothesis which represents the movement of storm-areas as prolonged for many thousands of leagues, or indeed that which represents them perpetually in motion around given centres of cyclonic or anti-cyclonic areas, keeping pace with the great winds in their eternal circuit?

As a striking corroboration of all this we find—what might have been assumed on theoretical grounds—that the logs and special observations of the Cunard steamships show that a vessel bound from Liverpool westward encounters frequent advancing areas of low pressure, indicating a number of rapidly succeeding barometric hollows or depressions, "each with its own cyclonic wind-system, moving across the Atlantic as eddies chasing each other down a river-current."

The word *cyclone* has frequently, but incorrectly, been used as significant of an enormous or very violent meteor, as if its application was to be confined to the devastating hurricane of the West Indies or the terrific typhoon of the China seas. It simply means a storm which acts in a circular direction, and whose winds converge by radials or sinuous spirals, toward a centre, moving in our hemisphere in the opposite direction to that of the hands of a clock, and in the Southern Hemisphere in a contrary direction. Taking this as the definition of a cyclone, it seems clear, from observation alone, that all storms are to be regarded as cyclonic. Volumes have been written to prove that this is not the case. But we have only to examine a few series of weather-maps from week to week to see that, wherever you have an area of low barometer, into its central hollow the exterior atmosphere from all sides will pour, and that in so doing a rotatory spiral or vorticose storm is generated. The tornado, the simooms, the dust-whirlwind, the fire-storm, even the slow and sluggish storm which moves on our western plains as the labouring wheel of the steamship buried in a heavy sea, all attest that a body cannot move on the earth's surface in a straight line. It

is not more true with us that the Gulf Stream turns to the eastward, the Polar Stream to the westward, and the equatorial currents to the northward, than that every air-current, in obedience to the same law, should turn to the *right* of the line along which from any cause it is called to move. The meteorist has therefore only to ascertain by observation where the barometer is lowest, to know at once the direction of the winds from the circumjacent districts, far and near, or at least to test the mathematical law by a grand experiment.

The tangential and centripetal forces, acting at the same time on any particle of air in the storm, may be equal or very unequal, and the cyclonic character of the gale may be well marked or partly concealed. In the tornado, with a diameter of only a few hundred feet, the tangential force may not be appreciable to an observer,

FIG. 1.—Cirrus and Cirronus Clouds.

but it is present, and intensely assists in communicating vorticose motion to the storm, whose roar is heard with awe by the stoutest heart, as it crashes through the forest and even ploughs up the soil of the earth. If the cyclonic or spiral feature should fail to manifest itself in any storm, we ought to look for such failure in the tornado. It is

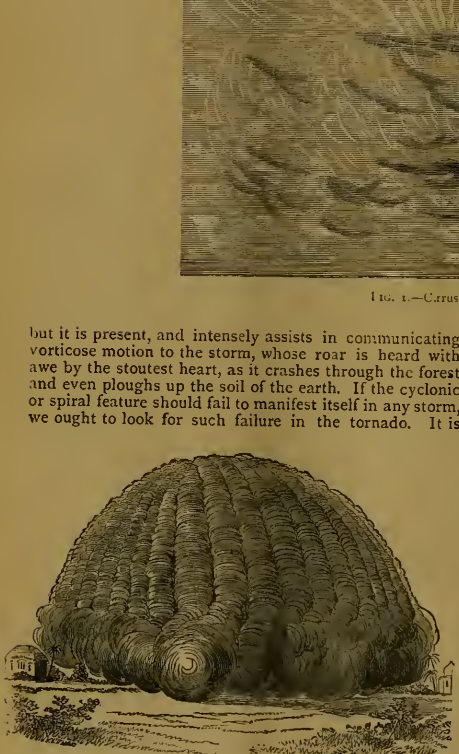


FIG. 2.—The Dust Whirlwind.

true that no barometric readings have ever been taken in the narrow heart of a tornado, but abundant evidence exists of the fearful rarefaction in the centre. While the meteor, once set in motion, may move forward with great velocity and destructiveness, the danger is clearly due to the intro-rushing and gyratory winds. There is not an instance, it is believed, recorded in which a tornado moved as much as 100 miles an hour; probably one-half that velocity would be too high an estimate for its usual and ordinary motion. But the wind, moving straightforward at the rate of 60 or 80 miles an hour, never worked anything like the disaster of a tornado. In the West-Indian hurricane, blowing at the rate of 100 miles an hour, houses have been blown down, ships innumerable stranded; but this is all mere child's-play compared to the suction and whirl of the tornado. The conclusion forced upon us is, that the ravages of the latter are due, not to the weight of the atmosphere, moving as a river-torrent in a straight line, nor to the rush of air behind the travelling vacuum, but to the torsive, racking motion—imparted to every object in its path—due to its gyration. To prove that this gyration is *always* from right to left, or against the hands of a watch, is, of course, practically impossible; but such a direction has often been observed in tornadoes.

It may, therefore, be safely concluded that, for all processes of meteorologic calculation, the disturbance, if not such at first, will soon become cyclonic. All daily weather-charts demonstrate this, not by a laboratory or lecture-room experiment, but on an infinitely wider and grander scale, and in a manner far more conclusive than any merely manual experiment could possibly make to appear. As Mr. Laughton has happily said, "Nature makes no distinction between small and great; the drop of mist that lights gently down on a delicate flower, and the avalanche that sweeps away a village, fall in obedience to one universal law."

(*To be continued.*)

*THE CORONAL ATMOSPHERE OF THE SUN**

I.

I PROPOSE to bring before you rapidly the principal results obtained by me during the last total eclipse of the sun which I observed in Hindostan, at a point not very far distant from the place where I observed the great eclipse of 1868, which opened up such new horizons with regard to the constitution of the sun.

The last eclipse took place on December 12, 1871. The chief interest of the phenomenon is connected with the problem of the luminous corona which surrounds the sun during total eclipses. When that body is eclipsed by the interposition of the moon, you know that independently of those jets and luminous expansions which are known as protuberances, there is seen around the dark disc of our satellite a magnificent luminous phenomenon, resembling a glory or crown, which extends to 8′, 12′, 15′, and more from the lunar limb, and the frequent strange forms of which are variable at each eclipse. The observation of the eclipse which now occupies our attention, had for its object to definitely fix for us the nature of this singular phenomenon.

The corona is the luminous manifestation which is predominant during a total eclipse, and thus it must, at all times, attract the attention of observers. We possess, indeed, descriptions by Plantade, by Halley, by Louiville, and by others, which go back to the commencement of the 18th century; of course these observers did not indicate the cause of the phenomenon.

Arago and his school form a period in the history of the attempts which have been made to discover the nature of the corona. Our great physical astronomer applied the polariscopic methods to these investigations, but he as well as his successors were baffled. In the "Astronomie Populaire," published in 1856 (tome iii. p. 604), we read the following conclusion upon this

subject: "I regret to say that the disagreement which has been found to exist between the observations made in different places by astronomers equally competent, on the luminous corona, in one and the same eclipse, has covered the question with such obscurities, that it is in the meantime impossible to arrive at any certain conclusion on the cause of the phenomenon."

By means of spectrum analysis the question has entered on a new phase. In 1868, while the nature of the protuberances was discovered, the spectrum of the corona was also obtained; it is true the observers found it continuous,† not an exact observation according to me, which retarded the solution of the question.

In the following year the Americans took up the matter.* They still found the continuous spectrum, but they established the existence of that celebrated green line (1474 in Kirchhoff's scale) which is the prevailing manifestation in the spectrum of the corona, and the meaning of which has yet to be discovered. We owe, moreover, to the Americans some very beautiful photographs of the protuberances, which show also the actinic power of the coronal light.

The eclipse of 1870 was marred by the bad weather. The few observations which could be made confirmed in general the observations of 1869.†

Thus, in 1871, we already possessed some very important data on the corona. Unfortunately these data were as yet incomplete, and above all inconsistent: for

* Translation of paper read by M. Janssen at the Bordeaux meeting of the French Association for the Advancement of Science.

† Let us mention the observation of M. Rayet, who found luminous prolongation on the principal lines of the spectrum of a protuberance.

* The total eclipse of August 7, 1869, visible in N. America.

† We should mention, nevertheless, the beautiful observations of Mr. Young on the reversion of the lines at the base of the chromosphere.

example, the continuity of the coronal spectrum, on the one hand, was inconsistent with the observations of polarisation of the corona, and on the other hand, led to the scarcely admissible conclusion of a corona formed of solid or liquid incandescent bodies. Thus the new eclipse, which presented a new opportunity of attacking this great question, the calculation of which, it was felt, must now be near, excited a general rivalry.

England took the most considerable share in these observations. The [British Association, the] Royal Society, the Royal Astronomical Society, the Indian Government, worked harmoniously together. Among the noted men of science sent out, we shall mention specially Mr. Norman Lockyer, Colonel Tennant, Lieut. Herschel, Mr. Pogson, Capt. Fyers, &c. Italy was represented by M. Respighi, who was destined to make, on this occasion, some very beautiful observations; Holland by M. Oudemans, &c. At the request of the Academy and the Bureau des Longitudes, I was appointed by the French Government to represent France. It was a glorious charge for me, but at the same time a heavy one, which made me regret that circumstances did not permit of my having any French rivals.

The voyage being decided, it remained for me to settle the plan of my observations, the plan on which to set about to choose instruments, and to choose the place of observation. These points were of prime importance.

With regard to the plan of investigation, I knew very well that, coming after so many able men, I could not hope to solve the problem by simply adding to the numerous observations already made, a few similar observations. It was necessary to study the collection of known facts, to fix the obscure or contradictory points, and to secure a number of rapid observations (the totality would last only about two minutes in India) which should enable us to correct what was inaccurate, to complete what was insufficient, and to form, along with previous observations, a collection of data from which to deduce the true nature of the phenomenon. For example, I had no doubt, in spite of contrary observations, that the spectrum of the corona was not really discontinuous. I was persuaded that it must present, as a dominant characteristic, that of a spectrum of gas, and I found an explanation of the contrary appearances recorded in the feebleness of the light of the corona which did not admit spectra to be obtained, sufficiently luminous for discerning their true constitution. Thus, my intention was to bring my efforts to bear upon this chief point, to some extent the knot of the problem. The point was to obtain a spectrum much more luminous than those of my predecessors. For this purpose I constructed a special telescope having a mirror 37 centimetres in diameter, and a focus of $1^{m}43$, which gave spectra about 16 times more luminous than those of an ordinary astronomical telescope.

I attached also great importance to seeing the corona at the same time as I analysed its light. A special arrangement of the finder enabled me to attain this end.

Finally, a polarising telescope placed upon the large telescope enabled me to join the polariscopic indications to the other data, and to judge of their agreement. Such were my instrumental arrangements.

The choice of a station was of no less importance. At the point at which we had arrived, our investigations bore upon phenomena so delicate that a sky was required of absolute purity, if I may be permitted the expression. Let us say a few words as to where I sought to realise this second condition.

The eclipse was to be total in the south of Hindostan, at Ceylon, Java, and Australia. Australia was too far away. Java is, in December, subject to the rainy monsoon. There yet remained India and Ceylon, which represented for the line of totality a very considerable exentt, and offered a very great variety of stations from which to choose. To make this choice, I resolved not to trust to the general indications which we possess in Europe as to the climate of India, but to set out early, to visit all the stations, and to decide only after visiting the places, and collecting information on the spot.

I was at Ceylon by the beginning of November, nearly six weeks before the time of the eclipse, which would take place on December 12. On this island I was greatly assisted by the families Laggard and Ferguson, to whom I here beg to express my thanks. The information gathered in the north of the island, where the phenomenon would take place, was not so satisfactory as I desired, and it was agreed to seek for better fortune on the coast of Malabar. I then left Ceylon for Malabar, doubling Cape Comorin. On my way I made some magnetic determinations, and I had the good fortune to find that the magnetic equator, for the dip, passes quite close to Cochin. It was at Telecherry, an English post situated near the line of totality and the French colony of Mahé, that we disembarked. I was received by M. Baudry, a French merchant, who gave me a most gracious welcome and the most active assistance. Mahé was very valuable to me; our governor, M. Liotant, procured for me interpreters who spoke French and the dialects of the districts I was to traverse.

I had, meantime, to choose between the coast proper, the plain, and the stations of the Ghauts and the Neilgherries. As the eclipse was drawing near I could not think of sojourning at each station to make a lengthened investigation. I decided to utilise the telegraph and the railway* for making a simultaneous inquiry as to these stations. M. Baudry, whom I had instructed in observations to make every morning at the hour of the eclipse on the purity of the atmosphere at the coast, sent me these every day by telegraph. I had a similar station on the plain. The baggage had been taken to Coimbatoor, at the centre of the railway, ready to be conveyed speedily to the station selected. I myself visited the Neilgherries, and to gain time, I surveyed these mountains by utilising the night. The mass of information thus collected indicated the great superiority of the Neilgherries. A very careful investigation of this massive mountain-range induced me to locate my station in the north-west, where I had in fact much finer weather than in Dodabetta, one of the highest peaks, where Colonel Tennant and Lieutenant Herschel were afterwards established.

It was upon a mountain near Shoolor, an Indian village, lat. 11° 27′ 8″ N., long. 74° 22′ 5″ E. of Paris, that I fixed my observatory. The instruments were forwarded from Coimbatoor (at the foot of the Neilgherries) to Ootamacund in ox waggons. From Ootamacund to Shoolor the country consisted only of mountain and forest, without carriage roads, and the cases had to be carried on men's shoulders, the many difficulties attending which were happily overcome. Three days before the eclipse the observatory was erected, the instrument in place and ready for observation.

The observation at Shoolor was favoured by a sky of wonderful purity. As I have already indicated, my plan was to examine the corona from the triple point of view of its figure, its spectrum, and its phenomena of polarisation.

I first examined the corona in the telescope; the phenomenon was seen in all its splendour. The general form was that of a curvilinear square (*carré curviligne*), of which the outlines were irregular, but clearly defined. At its greatest height, the corona extended to about 14′ or 16′ from the lunar limb, and only to about half that distance at its narrowest parts. No diagonal was in the direction of the solar equator. All around the limb of the moon were seen trains of light which united towards the highest parts of the corona, and which gave to the entire pheno-

* There is a railway from Madras to the Malabar coast. I found it almost follow the direction of the line of totality.

menon the appearance of a luminous and gigantic dahlia, the centre of which was occupied by the black disc of the moon.

The corona did not present any essential differences of structure at the point of contact and the opposite point. The motion of the moon did not appear to produce any change in the structure. These facts completely convinced me that the corona is a real object, situated beyond the moon, the gradual motion of which body reveals its various parts. Having finished this investigation, I turned my attention to the luminous elements of the phenomenon. My view being yet as distinct as ever, I commenced by examining the spectrum of the highest and least luminous parts of the corona. I placed the slit of the spectroscope at a point two-thirds of a radius from the moon's limb (*environ du bord lunaire*). The spectrum was seen much more vividly than I expected at that distance, a result evidently due to the luminous powers of the telescope and to the whole of the arrangements adopted. This spectrum was not continuous. I recognised at once the hydrogen lines and the green ray (1474).*

This is one point of the highest importance; I removed the slit, remaining always in the high regions of the corona; the spectra always presented the same constitution.

Starting from one of these positions, I descended little by little towards the chromosphere, examining very carefully the changes which might be produced. In proportion as I approached the moon, the spectra became more distinct and appeared richer, but they remained similar to the above in general constitution. In the middle heights of the corona, from 3′ to 6′ of arc, the dark line D was seen, as well as some obscure lines in the green; but these are at the limit of visibility. This observation proves the presence in the corona of reflected solar light, but it is seen that this light is drowned in an abundant extraneous (*étrangère*) luminous emission.

I then set myself to a very important observation, which I expected would give me the spectral relations between the corona and the protuberances. The slit was adjusted so as to take in a portion of the moon, a protuberance, and all the height of the corona. The spectrum of the moon was excessively pale; it appears due principally to atmospheric illumination, and gives a valuable idea of the feeble part which our atmosphere can play in the phenomenon of the corona.

The protuberance gave a very rich spectrum and one of great intensity; I had not time to make a detailed examination. The main point here is the establishment of the fact of the prolongation of the principal rays of the protuberance through all the height of the corona, which clearly demonstrates the existence of hydrogen in the latter.

The green line (1474), so vivid in the spectrum of the corona, appeared interrupted in the spectrum of the protuberance—a very remarkable result. I then gave a few moments to establish satisfactorily the exact correspondence of the lines of the corona with the principal lines of hydrogen in the protuberances.

There remained to me then only a few seconds for polariscopic observation.† The corona presented the characteristics of radial polarisation, and, it ought to be remarked, the maximum of effect is not observed at the lunar limb, but at some minutes from the edge.‡

I had scarcely finished this rapid investigation when the sun reappeared. JANSSEN

(To be continued.)

* My spectroscope was fitted with a very exact scale; but it will be seen how I afterwards made use of the lines of a protuberance as a scale.

† To study polarisation, I have an excellent lunette excellently constructed of biquartz, by M. Prazmowski. This polariscope, placed upon and adjusted to the telescope, can be consulted in an instant.

‡ M. Prazmowski has noted this fact in his excellent polariscopic observations of the eclipse of July 17, 1860.

NOTES

THE subject of the Transit of Venus in 1874 was for the first time officially brought before the notice of the Board of Visitors at the recent Visitation of the Royal Observatory. After a careful exposition of the matter by the Astronomer Royal, and a consideration thereof by the Visitors, it was proposed and seconded by the Astronomical Professors of Cambridge and Oxford, that the Government be requested to provide the means of organising some parties of observers in the Southern Ocean, in the hope that they may find some additional localities for observing the whole duration of the Transit of Venus. In other language, they recommend strongly a sort of *roving* expedition. The meteorological and climatic difficulties both North and South are extremely great: the practical difficulties in the South are very peculiarly so; in despite of the latter, the Board of Visitors were unanimous in their advice to try what best can be done in the sub-antarctic regions. The Astronomer Royal expressed his perfect acquiescence in the proposal of the Visitors; the final decision will rest with the Admiralty and the Government. In coming to this decision, it is proper to add that the Board was in no degree either influenced or assisted by certain discussions which have taken place upon the subject out of doors; their decision would have been just the same whether these discussions had or had not taken place; and the Board came to their conclusion under a full knowledge of the very peculiar climatic and navigational difficulties which seem to attend on the roving expedition which they recommend. It is, in fact, only a realisation of an old proposal by the Astronomer Royal himself, which seems to have been set aside on account of the many serious practical difficulties attending it. The Astronomer Royal also proposed to organise some additional stations dependent on Honolulu.

MESSRS. SAMPSON LOW AND MARSTON are about to publish a volume on the subject of Arctic Exploration, by Mr. Clements Markham, entitled the "Threshold of the Unknown Region." It is intended to give a full account of all that is known of the line which, at present, separates the known from the unknown; to explain the best route by which the unexplored region may be examined; and to enumerate the important scientific results to be derived from Arctic exploration.

NATURALISTS will be glad to hear that the long-talked-of new buildings for the National Museum of Natural History, at South Kensington, have been actually commenced, and that the contractors, Messrs. Baker, have arranged to complete them within three years.

MR. F. T. WARNER, of Winchester, who for some time has been collecting materials for a Flora of Hampshire, has kindly offered the use of his collections and materials to Mr. Frederick Townsend with the proposal that he should complete the Flora. Mr. Townsend has accepted the offer, and as much work remains to be done, he invites the assistance of other botanists in furnishing him with lists of plants or in forming these during the present season. The value of lists will be greatly increased if accompanied by specimens, and in all cases exact localities and dates should be given. It is proposed to divide the country into river-basin districts. Letters should be addressed to Shedfield Lodge, Fareham, but parcels to Botley Station, London and South Western Railway. Mr. Townsend will gladly pay postage or carriage of parcels.

PROFESSOR ROLLESTON, of Oxford, is appointed to deliver the Harveian Oration at the Royal College of Physicians on June 25, at five o'clock.

IT is rumoured that Prof. Tyndall is to receive the honorary degree of D.C.L. from the University of Oxford during the Commemoration.

THERE will be an election at Magdalen College, Oxford, in October next, to not less than six Demyships and one Exhibition. Of the Demyships, one at least will be mathematical, one at least in Natural Science, and the rest classical. The Exhibition will be in Natural Science. The stipend of the Demyships is 95*l.* per annum, and of the Exhibition 75*l.*, inclusive of all allowances; and they are tenable for five years, provided that the holder does not accept any appointment which in the judgment of the electors will interfere with the completion of his University studies. The examination for the Mathematical and Natural Science Demyships will be held in common with Merton College, at the same time and with the same papers. Each candidate will be considered as standing in the first place at the College at which he has put down his name, and, unless he shall give notice to the contrary, will be regarded as standing at the other College also. In conducting the Examination for Magdalen College Demyships in Natural Science, questions will be put relating to General Physics, to Chemistry, and to Biology, including Human and Comparative Anatomy and Physiology, with the principles of the classification and distribution of Plants and Animals; but a clear and exact knowledge of the principles of any one of the above-mentioned Sciences will be preferred to a more general and less accurate acquaintance with more than one. The Examination in Biology and Chemistry will be partly practical, if necessary. Candidates for Demyships in Natural Science and Mathematics have also to satisfy the Electors of their ability to pass the ordinary Classical Examinations required by the University. Very superior excellence, however, in Natural Science or Mathematics will be allowed to compensate for any deficiency which Candidates may show in the Classical part of the Examination, provided that the Candidate, if elected, undertake to make up this deficiency at a subsequent period. The next Examination will commence on Tuesday, October 7, at 9 A.M. Particulars relating to the examinations in the various subjects may be obtained by applying to the senior tutor.

THERE will be an election at Merton College, Oxford, in October next, to three Postmasterships, value 80*l.* per annum, tenable for five years, or so long as the holder does not accept any appointment incompatible with the full pursuance of his University studies. One of these Postmasterships will be awarded for proficiency in Mathematics, two for proficiency in Physical Science. In the examination for the Mathematical Postmastership, papers will be set in Algebra, Pure Geometry, Trigonometry, Theory of Equations, and Analytical Geometry of two dimensions. Candidates for this Postmastership must not have exceeded four terms of University standing. There is no limit of age. In the examination for the Physical Science Postmasterships, papers will be set in Chemistry, Physics, and Biology; and an opportunity will be given of showing a knowledge of practical work in Chemistry and Biology. The Postmasterships will be given either for special excellence in one subject, or for excellence in two of the three subjects; but no candidate will be examined in more than two subjects. A paper will be set in Elementary Algebra and Geometry, which, *cæteris paribus*, will be of weight in the election to the Postmasterships. Candidates for these Postmasterships must not have exceeded six Terms of University standing. There is no limit of age. The examination will commence on Tuesday, October 7, at 9 A.M., in Merton College Hall. Candidates are required to call on the Warden on the same day between 4 and 5 P.M. The examination will be held in common with Magdalen College at the same time, and with the same papers. Each candidate will be considered as standing, in the first instance, at the College at which he has put down his name, and, unless he has given notice to the contrary, will be regarded as standing at the other College also.

FROM the report on the progress and condition of the Royal Gardens at Kew during the year 1872, just published by Dr. Hooker, it appears that the number of visitors to the gardens shows an increase of 6,000 over that in 1871, very nearly half the number being Sunday visitors. Considerable additions and improvements have been made during the year in various parts of the gardens; the Pinetum now numbers about 1,200 species of coniferous plants, including almost every species that can be grown out of doors in this climate. Seeds and living plants have been received from various parts of the world, and a large number of parcels sent off to our colonies and elsewhere. The acquisitions to the Museums have been considerable, and those to the Herbarium quite exceptional in magnitude and importance, including an extremely valuable presentation by the Rev. C. New of plants collected on the Alpine zone of Kilima-njaro, the only hitherto visited snow-clad mountain in Equatorial Africa; 2,000 Brazilian plants from M. Glaziou, Director of the Botanic Gardens at Rio de Janeiro; and a beautiful collection of Appalachian mosses from Prof. Asa Gray of Cambridge, U.S. Among the publications issued during the last year either officially or by private botanists working at Kew, are the commencement of the second volume of Bentham and Hooker's "Genera Plantarum," the sixth volume of the "Flora Australiensis," by Mr. Bentham; the first part of the "Flora of British India," by Dr. Hooker; several parts of Martius's "Flora Brasiliensis;" Col. Grant's account of the plants collected by Capt. Speke and himself in Central Africa, &c.

SPECIAL certificates of proficiency have been taken at the recent examination for women of the University of London in the following scientific branches:—in Mathematics, by Miss Black and Miss Orme; in Chemistry and Natural Philosophy, by Miss Eaton and Miss Wood; in Human Physiology, by Miss Kilgour of the Ladies' College, Cheltenham, the first time this branch has been taken by a lady; and in Political Economy by Miss Lord and Miss Orme.

MR. GWYN JEFFREYS is about to join the *Challenger* at Madeira for a cruise to the Canaries, Cape de Verde Islands, and Bahia.

M. P. J. VAN BENEDEN describes, in the Bulletin of the Belgian Academy of Sciences, a fossil bird found in the Rupelian clay of Waes, in all respects similar to the existing *Anas Marila*.

LAST Saturday appeared the first number of a new French scientific periodical named *La Nature*. The articles are all high class, and the illustrations are plentiful and well executed.

DR. LEONE LEVI, the Consul-General for Paraguay, is arranging a scientific commission to inquire into the resources of Paraguay. The commission is to consist of botanical, agricultural, geological, mineralogical, and geographical surveyors. It is understood that the Consul-General has in view to appoint a French botanist, of great reputation, and a Scotch agriculturist, but has made no arrangement for the geologist and geographer. Dr. Levi would be glad to give information to anybody who might be willing to offer his co-operation in such a scientific expedition.

LETTERS from Sydney announce the arrival there of the Italian frigate, *Vettore Pisani*, with the naturalist D'Albertis on board, he having been forced to leave New Guinea by repeated attacks of fever. His companion, Odoardo Beccari, well known for the valuable collections he made between 1865 and 1868 in Borneo, and subsequently in N.E. Africa, and which are now in the civic museum of Genoa, has remained in New Guinea. Signor D'Albertis is coming overland to London, and will bring with him a large collection of Zoological specimens.

The second of the two parts of Prof. C. J. Sundevall's new Synopsis of the Classification of Birds has just reached us from Stockholm. This important contribution to ornithological literature, the work of so justly celebrated and painstaking an ornithologist, will be found replete with suggestions, as its author bases his methods of arrangement on details worked out mostly by himself, and with a truly scientific spirit. Some of the arrangements suggested are particularly striking, and though they will probably not all bear the test of future inquiry, yet are undoubtedly based on characters, the importance of which has been too little attended to. Among these peculiarities may be mentioned the placing of the Hoopoo with the Larks, quite away from *Irrisor;* and the adoption of Strickland's eccentric idea that the Pratincole is only a modified Nightjar; to say the least, would it not be more reasonable to call the Nightjar a modified Plover?

The correspondent of the *New York Herald* at Khartoum writes to that journal as follows, under date of April 30:—Three boats engaged in the ivory trade arrived from Gondokoro, April 7, with direct news that Sir Samuel Baker and family were well at Fatuka in the month of February. The reinforcement of 200 men which went forward from Gondokoro reached Baker, at Fatuka, February 5. It was said that with these troops Baker would renew his march towards the Albert Nyanza and the territory of Kaberego (formerly Kamrasi). We are hourly expecting the arrival of a fleet of nineteen Government vessels with mails, which will doubtless bring full particulars of Baker's recent movements.

In No. 145 of the *Gazzetta Ufficiale del Regno d'Italia*, Prof. Lorenzo Respighi, director of the observatory at Campidoglio, gives an account of his observations of the eclipse of May 26. He states that though the maximum phase was so small as to be of little importance, he considered it a good opportunity for making spectroscopic time observations. The method is very simple, and is well known to spectroscopists; it need only be said that it consists in observing accurately the moment at which the dark body of the moon cuts out one of the chromospheric bright lines. Prof. Respighi observed the C-line and was able to perceive the moon's approach across the chromosphere about one minute before first contact, which took place at 46°·30′ from north towards the west point of the sun at 8h. 42m. 35·9s. Roman mean time. The greatest phase occurred at 9h. 7m. when 0·05 of the sun's diameter was covered. The last contact was observed at 10° from the north towards west at 9h. 31m. 3·4s. Roman mean time. The dark moon was seen passing over the chromosphere for about a minute after last contact. The Sicilian expedition had before noticed the power which the spectroscope gave of observing the first and last moments of contact before the times given in the Nautical Almanac, and there can be no doubt that this method is of very great value for time observations of eclipses and transits. Unfortunately in the latter cases it is almost or quite impossible to keep the slit at the exact point at which the body is expected to enter the solar disc on account of the difficulty in obtaining perfect adjustments of the driving clock, &c. It might however be possible to follow the body in transit across the sun and note the exact time of last contact.

We have received the fifteenth report of the East Kent Natural History Society, containing reports of the scientific meetings for the year 1872, and various statistical reports. The society has probably never been in a more prosperous condition as to funds and members, the number of the latter being reported as 109, and the reports of the meetings show that the society is in good working trim. Prefixed is a brief but pointed address by the President, Dr. Mitchinson, in which he points out the utility and some of the dangers of Provincial Natural History Societies. He refers to one evil which is apt to result from the labours of such societies, an evil which has with justice been animadverted on from various quarters recently, viz. a morbid mania for indiscriminate collecting, which is apt to lead to the extinction of the rarer fauna and flora of a district. No doubt, as Dr. Mitchinson says, collecting is inseparable from the thorough study of botany and zoology; but, as he forcibly remarks, no surer sign exists of a spurious pursuit of either or both of these sciences than when rare plants are torn up, and rare animals made still rarer by that selfish acquisitiveness which passes with so many for a love of science. It is the duty of every Natural History Society to discourage such a practice.

The discovery of another planet, No. 131, is telegraphed from America.

It has been resolved by the United States' Government to hold an investigation into the circumstances connected with the loss of the Arctic exploring ship *Polaris* and the death of her commander, Captain Hall.

The publication of the West Kent Natural History, Microscopical, and Photographic Society, is mainly occupied by two valuable and extremely interesting addresses by the president, Mr. J. Jenner Weir, F.L.S. The first was delivered at the annual meeting in February last, and consists chiefly of some careful observations and facts illustrating the doctrine of evolution in the animal kingdom. His other address was delivered at a *soirée* held at the Crystal Palace, its subject being "The Aquarium and its Contents," Mr. Weir noticing some of the most remarkable facts connected with the organisation and habits of the different classes of animals in the aquarium. We are glad to see from the Council's report that the Society continues prosperous and efficient.

Additions to the Brighton Aquarium during the past week:—One Sturgeon (*Accipenser sturio*), from Rye Bay; Smooth Hounds, or Skate-toothed Sharks (*Mustelus vulgaris*); Toper, or White Hound (*Galeus canis*); Gurnards (*Trigla lyra et lineata*); Lesser Weevers (*Trachinus vipera*); Scald Fish (*Arnoglossus laterna*); Sea Trout (*Salmo trutta*); Surmullet (*Mullus surmuletus*); Conger Eels (*Conger vulgaris*); Octopus (*Octopus vulgaris*); Lobsters (*Homarus vulgaris*); Sea Crayfish (*Palinurus vulgaris*); Sea Cucumbers (*Cucumaria pentactes*); Zoophytes (*Alcyonium digitatum, Tubularia indivisa, Pleurobranchia pileus*).

The additions to the Zoological Society's Gardens during the past week include a Grey Ichneumon (*Herpestes griseus*) from India, presented by Mrs. W. Simpson; an Eyed Lizard (*Lacerta ocellata*) from S. Europe, presented by Mr. T. Blackmore; a Loggerhead Turtle (*Thalassochelys caouana*) from the Atlantic Ocean, presented by Lieut. N. Clark; a Rough-legged Buzzard (*Archibuteo lagopus*) from Europe, presented by Mr. W. Stokes; a Blotched Genet (*Genetta tigrina*) from W. Africa, presented by Mr. A. B. Worthington; two Emus (*Dromæus novæ-hollandiæ*) from Australia, presented by Hon. Sir A. Gordon; a Persian Gazelle (*Gazella subgutturosa*), presented by Captain Phillips; seventeen Turtle Doves (*Turtur auritus*) and a Barbary Turtle Dove (*Turtur risorius*), presented by Mr. Gassiot, Jun.; two Lions (*Felis leo*) from Persia; a Wapati Deer (*Cervus canadensis*) from N. America, purchased; four Trumpeter Swans (*Cygnus buccinator*) and a Purple Kaleege (*Euplocamus horsefieldii*) hatched in the Gardens; four Aldrovandi's Lizards (*Plestiodon auritus*) and two Ocellated Skinks (*Seps ocellatus*) from N.W. Africa, deposited.

ON MUSCULAR IRRITABILITY AFTER SYSTEMIC DEATH*

THE object of the lecture was to put forward certain facts the author had learned on the phenomenon of muscular irritability after systemic death. He included in the same study certain examples in which muscular irritability has for a time ceased, but has become re developed under new conditions. He thus included the study of those states which favour the continuance of irritability or which destroy it, and those conditions which suspend it but do not destroy it. By this method of research the author thinks we may proceed backwards towards living irritability, and may determine upon what that depends with more facility than by experimenting on the phenomena of irritability in the living animal. He imagines that if he knew nothing of the construction of a watch, or why for a certain time a watch maintains its motion, and if he had nobody to teach him these things, he might be better able to arrive at the fact he wanted by trying to set the motionless watch into motion than by interfering with it while it is in motion.

The record of experimental endeavour carried out with the design above explained, included a review of the work of twenty-five years. The subjects brought under consideration were arranged as follows :—

(1) The effect of cold on muscular irritability after systemic death.

(2) The effect of motor forces, mechanical, calorific, electrical.

(3) The effect of abstracting and supplying blood.

(4) The effect of certain chemical agents, organic and inorganic.

Effects of Cold

Previous to the time of John Hunter it was supposed that cold was the most effective agent for destroying muscular irritability. The effects of cold employed in various ways in the author's experimental researches were now detailed systematically. The effect of cold in suspending the muscular irritability of fish, reptiles, and frogs was first described. On all these animals it was shown that cold could be made to suspend without destroying the muscular irritability, for a long period of time, and that in fish, carp (on which the author had made the greatest number of experiments) the restoration of irritability could be perfected to the extent of the restoration of the living function.

Passing to warm-blooded animals, the author showed that in the process of cooling in every animal that has been suddenly deprived of life without mechanical injury, there is a period in the process when general muscular irritability may be made manifest. He demonstrates this fact by the simple experiment of throwing a current of water heated to 120° Fahr. over the arterial system of the recently dead animal. If the surrounding temperature be high at the time of this experiment, the operation should be performed within a few minutes after death ; but if the temperature be below freezing-point, it may be delayed for a long period. In one experiment the author reproduced active muscular contraction in an animal that had lain dead and exposed to cold, 6° below freezing-point, for a period of three hours. In this case the muscles generally remained irritable for seven minutes after the injection of the heated water, while in the muscles of the limbs, by repeating the injection at intervals, the irritability was maintained for two hours.

The author drew a comparison between these experimental results and the phenomena of muscular irritability that have been observed in the human subject after death by cholera. The movements were not conscious, nor were they promoted by electrical excitation ; but the flexors and extensors belonging to each part in which there is movement are alternately contracted and relaxed as if from some internal influence.

The influence of cold in suspending without destroying muscular irritability was further evidenced by the experiment of subjecting some young animals to death by the process of drowning them in ice-cold water. It was shown that in the kitten the muscular irritability may be restored to the complete re-establishment of life after a period of two hours of apparent systemic death, and although the muscles when the animal is first removed from the water give no response to the galvanic current. This same continuance of irritability after apparent systemic death by drowning in ice-cold water has been observed in the human subject, not in so determinate, but in an approximated degree. An instance was adduced in which a youth who had been deeply immersed for twelve minutes in ice-cold water retained muscular irritability so perfectly that he recovered, regained consciousness, and lived for a period of seven hours.

Commenting on the method of restoration of irritability, the author showed that a certain period of time is required before the irritability is raised from a mere passive condition, in which it responds only to external stimuli, into the condition necessary for independent active contractility. The change of condition from the passive to the active, when it does occur, is so sudden as to seem instantaneous at first, then it is slowly repeated. This rule holds good in respect to voluntary muscles and involuntary. It is specially true in regard to the heart, which organ, the author states, may perform its office under two distinct degrees of tension or pressure—a low tension, in which the organ itself is reduced in size, and moves almost insensibly ; and a full tension, in which it is of larger size, and moves with a sufficient power to impel the blood so as to overcome the arterial elasticity and the capillary resistance.

Another fact bearing on this subject is that in rapid decline of muscular irritability the muscles most concerned in the support of the organic functions, namely, the heart and the muscles of respiration, are the last to yield up their spontaneous power ; but when they have lost their power, they are the last to regain it. To this rule there is one exception, viz., in the muscular fibre of the right auricle of the hear..

The author then explained that the degree of cold which suspended irritability is fixed within certain measures of degree, from 38° to 28° F. being the most favourable degrees of exposure.

Effect of Motor Forces

Cold, by the inertia it induces, suspends, under certain conditions, but does not destroy muscular irritability. The motor forces, on the contrary, quicken the irritability for a brief period, and then completely destroy it. The mode in which all the motor forces act in arresting irritability is by the induction of a contractile state, which, once established, remains permanent. The author here related his experiments on the effect of the different forces upon the right auricle of the heart, and reported as the result of his observations that, while all the forces act ultimately alike in producing permanent contraction, the mechanical excitation is much slower than the calorific ; while electrical excitation appears to hold an intermediate place, as if it were a combination of mere mechanical motion with an increased temperature. Electrical tension may nevertheless be increased so as to rival heat in its immediate effect on contraction.

The author here traced out the results of a series of short sharp irritations of muscle with a needle-point, and compared them with the effect of a blow, showing that in each case rigidity follows, but is much slower in development when it is excited by the needle.

The influence of heat in destroying irritability by its power in producing permanent contraction was described from experiments bearing on the relation of temperature to the muscular contraction of different animals—frogs, pigeons, and rabbits. It was shown that a relative rise in temperature in each class, a rise averaging 12° in Fahr. scale, from the natural temperature of the animal was the efficient for producing permanent rigidity, the cause of the ultimate rigidity being coagulation of the myosine.

The effect of electrical excitation is in the same direction, but is varied according to the mode in which the excitation is performed. Discharge from the Leyden jar produces contraction, which is permanent or intermittent in accordance with the mass of the muscle and the intensity of the discharge. This fact was elucidated by reference to a series of experiments with a Leyden battery, placed in cascade, and the effect produced by the discharge from 96 feet of surface upon animals of different sizes and weights, from sheep down to pigeons, as well as on sections of the bodies of the same animals immediately after death. The experimental facts demonstrated that with an efficient discharge the whole muscular system of a small animal could be fixed instantly in the rigidity of death, and that the precise position of the animal at the period immediately preceding death was retained with such perfection, so sudden was the change, that nothing but physical examination by the hand could bring to the mind the fact that the animal had passed from life into death.

But the same shock passed through a sheep weighing 54 pounds produced only a temporary contraction of muscle,

* The Croonian Lecture, by Benjamin W. Richardson, M.A., M.D., F.R.S.

and required repetition before the rigidity was rendered permanent.

By employing discharges of less tension it was found that muscles, or special tracts of muscles, in the same animal immediately after its death, could be made rigid quickly or slowly by variation of the intensity of the discharge.

The effect of the intermittent electro-magnetic current was next brought forward, and was shown to resemble closely that of the simple electrical discharge from the Leyden phial.

Intensified it induces permanent contraction; and if it be repeated even with low tension, so as to call forth contraction, it destroys the irritability, *cæteris paribus*, more quickly than if the muscle had been left to itself.

Parenthetically, the lecturer dwelt here on the common practice, after sudden death, of endeavouring to excite the action of the enfeebled heart by passing through it an electrical current. Some practitioners, said the author, have gone so far as to introduce a needle into the heart itself, and to make the needle act as one of the conductors from a battery. Such experimentalists, before they undertake this operation on the human subject, should at least observe the effect of the agency they are employing on the exposed heart of an inferior animal recently and suddenly killed by drowning or by a narcotic vapour. They would learn then with what infinite facility the muscular irritability of the heart, in all its parts, is excited for a moment only to be permanently destroyed. They would learn that if blood be not passing through the muscular structure concurrently with their exciting current, they could not more effectually arrest function than by the very method they have adopted to sustain it.

The influence of the continuous current on muscular irritability was introduced by the author, together with a special reference to the first experiments of Aldini on the bodies of malefactors who had been recently executed; and it was shown from Aldini's most noted experiment how largely the phenomena of motion he induced in a dead man, and the recital of which caused so much sensation in the year 1803, was due, not to the galvanism, but to the circumstance that the dead body had been exposed for the hour after death and before the experiments commenced, to the action of cold two degrees below freezing-point. On the whole the continuous current acts on muscular fibre after the manner of heat. If the muscle, recently dead, be exposed to cold, the current, when sufficient, restores for a limited period the irritability, and finally destroys it by inducing persistent contraction. If the muscle, recently dead, be left at its natural temperature, the current simply shortens the period of irritability by quickening contraction.

Abstraction and Supply of Blood

Under this head the author first considered the effect of abstraction of blood from the living muscular fibre. He showed that when the flow of blood was very rapid, there was invariably a given period of muscular excitation. In sheep killed in the slaughterhouse he found that this muscular excitement occurred at the time when the proportion of blood removed from the animal was equivalent to about the 320th part of the weight of the animal. The increased irritability passes rapidly into general convulsion without consciousness, and, as a rule, ceases for a time with a temporary cessation of further loss of blood. After this the irritability remains, if the bleeding be arrested altogether, and can be called into action by any external stimulus, although it is rarely spontaneously manifested when the vessels are left divided and open. After an interval of one or two minutes there is a recurrence of loss of blood, followed by a muscular excitement which marks the moment of systemic death.

The fact of the two stages of exalted muscular irritability during abstraction of blood is important, as indicating the two different tensions of muscle to which reference has already been made. The first convulsive action, convulsion of syncope, marks a definite period, when the tension of the heart and therewith the whole vascular system is reduced to a degree of action well defined and attended with definite phenomena. The second excitement, convulsion of death, indicates the period when the passive or lower tension of the muscular power ceases.

A distinction was here drawn by the author between the muscular conditions present during syncope and during death. Syncope, it was urged, means the continued action of the heart at a low tension, from which it can be suddenly raised into full tension with restoration of the powers of life; death means the cessation of the lowest tension at which the heart can effectively work.

It was shown that in all the cases of restored animation after apparent death, the condition of the heart was that of a muscle acting under the lower degree of tension.

The experiments of the author for re-establishing artificial respiration together with artificial circulation, and of these combined with electrical excitation of the nervous centres, were next referred to; but as they had already formed the subject of a paper read before the Society, they were but briefly dwelt upon.

Effect of some Chemical Agents

In this portion of his lecture the author adduced a series of experimental researches with various chemical substances, organic, inorganic, and intermediate, which tend to prolong the period of muscular irritability by diffusion through the tissues of animals recently dead. These substances, which suspend irritability, act in two ways. Some, like chloride of sodium and other soluble saline substances, act merely by holding the coagulable fluid of the muscular tissue in a continued state of fluidity; others seem to have a different action, and to hold the nervous function also in suspense. The nitrite of amyl and other members of the nitrite series belong to this last-named class of agents, and some of the cyanogen bodies exert a similar influence. In experiments with nitrite of amyl on cold-blooded animals (frogs), the author had suspended muscular irritability for a period of nine days, and had then seen it restored to the extent even of restoration of life. In one instance this restoration took place after the commencement of decomposition in the web of the foot of the animal. In warm-blooded animals a series of suspensions had been effected by nitrites and also by cyanogens, not for so long a period, but for periods of hours, in one instance extending to ten hours.

In the whole series of his inquiries no fact had impressed the author more forcibly than this: that the muscular irritability, in so far as it belongs to the muscle, may be sustained for hours after the nervous excitation which calls it into spontaneous action has ceased. Hereupon he infers that after death the nervous matter undergoes a change of condition which, *in result*, is identical with that change in muscle which we call rigor. There is evidence, moreover, from some rare cases, that the final inertia of nervous matter may be suspended and revived, so that all the muscles may be reanimated. This point was elucidated by reference to the phenomena that had recently been observed by Mr. Wadsdale Watson, of Newport, Monmouthshire, on a double monster, drawings of which were placed before the society. In this instance two children were born so attached that the separation of them was impossible. Both lived equally for three hours after birth, and then one died and remained dead for three hours, while the other lived. At the end of the time named the dead child recommenced to breathe, and showed other signs of restored muscular power; then it sank into a seemed death, but at intervals of about four hours moved again; at length, twenty-three hours after its first apparent death, during a fit of crying of the living child, it recovered sufficient power to breathe and even to cry, and manifested evidence of life in all its muscles, except the heart, for twenty minutes, when it had a severe convulsion, which closed all further motion.

In this instance the author believed that the retention of spontaneous muscular irritability depended upon the retention in the nervous organism of the conditions necessary for independent action. He then concluded by giving a description of his researches as to the possibility of suspending nervous changes incident to death, so as to retain the conditions requisite for the communication of nervous impulse to muscular fibre.

SCIENTIFIC SERIALS

Annalen der Chemie und Pharmacie Neue Reihe, Band xci., Heft 1, May 6, 1873.—The number opens with a long paper by Oscar Jacobsen on the gases of sea-water. Notices of former researches on this subject are given. In a table the results of 95 analyses by the author are given with the localities of collection. These are in the North Sea and the Baltic.—On the oxidation of allantoin by means of potassic ferricyanide, by F. C. E. van Embden. The two bodies were mixed, one molecule of each, in solution, and the mixture acidulated with acetic acid. A crystalline precipitate was produced, having the formula $C_4N_3H_2KO_4$. This the author regards as the potassium

salt of the new acid $C_4N_3H_3O_4$, which he proposes to call allantoxanic acid. Various other salts are described. The acid is found to be bibasic.—On the action of sodium-amalgam on dinitrohephtylic acid, by H. A. Kullhem. The result of the action appears to be the formation of a monobasic acid having the formula $C_6H_{10}(NO_2)O_2$.—On the products of the decomposition of the chlorhydrin of glyceric acid, by Messrs. Werigo and Okulitsh.—On a new acid from aloes, by P. Weselksy. The body in question was obtained from Socotra aloes; its formula is, $C_9H_{12}O_4$ when dried in the air, and its anhydride has the formula $C_{18}H_{18}O_5$. The acid is apparently dibasic.—Dr. H. Sprengel communicates a paper on the water air-pump.—On liquid carbonic anhydride, by L. Cailletel, is a translation from the author's late paper in the *Comptes Rendus*—On the addition of cyanamide, by Dr. E. Baumann, is an account of the compounds formed when this body is added to various others.—On the combination of bromine and ether, by P. Schutzenberger, has already appeared in the *Comptes Rendus*.—An examination of a new alkaloid, by Prof. Hlasiwetz. The body in question is a product of the oxidation of cinchonin.—On the isomers of dinitrophenol, by H. Hübner and W. Schneider.—On the nature of sulpho and sulphonitrobibrombenzolic acid, by H. Hübner and R. Douglas Williams.—On the synthesis of carbazol and on phenathren, by C. Graebe.—Contributions to the history of the orcins, by J. Stenhouse, has already appeared in the Proceedings of the Royal Society, the present communication, No. III. of the series, deals with the amido-derivatives of those bodies.—On a new method of preparing carbonic tetrabromide from bromoform, by J. Habermann. The author acted on bromoform in the presence of potash with bromine. The mixture exposed to direct sunlight for 5–6 days gives a good product of tetrabromide. In the dark, after an exposure of three months, only a trace was formed. The reaction occurs as follows:—

$$CHBr_3 + Br_2 + KHO = CBr_4 + KBr + H_2O.$$

SOCIETIES AND ACADEMIES

London

Royal Society, May 1.—"On the Condensation of a Mixture of Air and Steam upon Cold Surfaces." By Prof. Osborne Reynolds.

The object of this investigation is to ascertain how far the pressure of a small quantity of air affects the power of a cold surface to condense steam.

The conclusions which the author draws from the experiments are as follows:—

1. That a small quantity of air in steam does very much retard its condensation upon a cold surface; that, in fact, there is no limit to the rate at which pure steam will condense but the power of the surface to carry off the heat.

2. That the rate of condensation diminishes rapidly, and nearly uniformly as the pressure of air increases from two to ten per cent. that of the steam, and then less and less rapidly until thirty per cent. is reached, after which the rate of condensation remains nearly constant.

4. That in consequence of this effect of air the necessary size of a surface-condenser for a steam-engine increases very rapidly with the quantity of air allowed to be present within it.

5. That by mixing air with the steam before it is used, the condensation at the surface of a cylinder may be greatly diminished, and consequently the efficiency of the engine increased.

6. That the maximum effect, or nearly so, will be obtained when the pressure of the air is one-tenth that of the steam, or when about two cubic feet of air at the pressure of the atmosphere and the temperature 60° F. are mixed with each pound of steam.

As this investigation was nearly completed, the author's attention was called to a statement by Sir W. Armstrong, to the effect that Mr. Siemens had suggested as an explanation of the otherwise anomalous advantage of forcing air into the boiler of a steam-engine, that the air may prevent, in a great measure, the condensation at the surface of the cylinder. It would thus seem that Mr. Siemens has already suggested the probability of the fact which is proved in this investigation. The author is not aware, however, that any previous experiments have been made on the subject, and therefore he offers these results as independent testimony of the correctness of Mr. Siemens's views as well as of his own.

"On the effect of Pressure on the Character of the Spectra of Gases." By C. H. Stearn and G. H. Lee.

May 8.—"Contributions to the Study of the Errant Annelides of the Older Palæozoic Rocks." By Prof. H. Alleyne Nicholson, M.D., F.R.S.E.

In this communication the author endeavoured to elucidate the abundant and obscure organic remains which are found so commonly in the Palæozoic Rocks, and especially in the Silurian strata of Britain, and which are generally known by the vague and convenient names of "Fucoids," "Annelide burrows," and "Tracks." After expressing his opinion that the first step towards the study of these obscure fossils lay in the provisional grouping and naming of the more marked forms which are already known to exist, the author proceeded to divide the remains under consideration into two great groups. In the first of these groups are those fossils which are truly the *burrows* of marine worms, as distinguished from mere trails and surface-tracks. Some of these burrows (*Scolithus*) are more or less nearly vertical in direction as regards the strata in which they are found; and they are to be looked upon as being true burrows of habitation. In this section are placed the genera *Scolithus*, *Arenicolites*, and *Histioderma*.

The second great group of Annelide remains comprises genuine surface-trails or "tracks," which of necessity never pass below the surface of the bed on which they occur.

"The Action of Light on the Electrical Resistance of Selenium." By Lieut. Sale, R.E. Communicated by J. N. Lockyer, F.R.S.

The following were the general results of the experiments:—

1. That the resistance of selenium is largely affected by exposure to light.

2. That this effect is not produced by the actinic rays, but is at a maximum at, or just outside the red rays, at a place nearly coincident with the locus of the maximum of the heat-rays.

3. That the effect of varying resistances is certainly not due to any change of temperature in the bar of selenium.

4. That the effect produced on exposure to light is sensibly instantaneous, but that on cutting off the light the return to the normal resistance is not so rapid.

It would seem that there exists a power in rays, nearly coincident with the heat-rays of high intensity, of altering instantaneously and without change of temperature the molecular condition of this particular element.

May 15.—"On Jeypoorite, a Sulph-antimonial Arsenide of Cobalt." By Major W. A. Ross, R.A. Communicated by Prof. H. Miller, Foreign Sec. R.S.

"Determination of the Number of Electrostatic Units in the Electromagnetic Unit made in the Physical Laboratory of Glasgow University." By Dugald M'Kichan, M.A.

The object of this paper is to describe experiments made at intervals from 1870 to 1872 in the Physical Laboratory of Glasgow University to determine the relation between the fundamental units in the two systems of absolute electrical measurement, the electromagnetic and the electrostatic. A summary is also given of the results of similar observations made by W. F. King in 1867 and 1868.

The two systems of electrical measurement, or the units which they employ, are founded on the fundamental units of time, mass, and space applied to the observed effects of electricity at rest and electricity in motion. The dimensions of quantity in the two systems are such that the ratio of the electromagnetic and the electrostatic unit of quantity is expressible as a velocity.

This velocity, usually known as v, is not only of great importance in all combinations of electromagnetic and electrostatic action, but it is also of great scientific importance in the theory of the propagation of electromagnetic disturbances through a dielectric medium. It occupies a very important place in the development of the electromagnetic theory of light by Professor Clerk Maxwell, according to whose theory this velocity v is the same as the velocity of light.

The first experimental determination of v was made by Weber from a common electrostatic and electromagnetic measure of capacity. The result of Weber's experiments was that v was $310{\cdot}74 \times 10^8$ centims. per second.

Another determination was made by Prof. Clerk Maxwell in 1868, by means of a direct comparison of electrostatic attraction with electromagnetic repulsion. His experiments gave $v = 288{\cdot}0 \times 10^8$ centims. per second.

The value of v given by the experiments here described is 293×10^8 centims. per second. The method employed was that of obtaining an absolute electrostatic and an absolute electro-magnetic measurement of the same electromotive force. v is defined as the ratio of the units of quantity in the two systems; but it follows from the definition of electro-motive force, that v is also the ratio of the units of electromotive force in the two systems.

The electromotive force, or the difference of potentials between the two poles of a constant Daniell's battery, was measured electrostatically by means of Sir William Thomson's absolute electrometer. The absolute electromagnetic value of this electromotive force was given by the effect of the current which it maintained in the circuit of an electrodynamometer. The determination of this value depended on the resistance of the electrodynamometer-circuit, which was reckoned in terms of the absolute value of the British-Association standard unit of resistance. Any correction which may hereafter be found to be applicable to the absolute value of this standard coil, as measured at King's College by Professors Clerk Maxwell, Balfour Stewart, and Fleeming Jenkin, must be applied to the value of v give above.

The comparisons made in 1867 and 1868 by Mr. King gave as the mean value of v, $284 \cdot 6 \times 10^8$ centims. per second. The experiments made in 1870 with the new absolute electrometer give as the mean result $v = 294 \cdot 5 \times 10^8$ centims. per second. The result of the later observations made under much more favourable circumstances was $v = 292 \cdot 4 \times 10^8$ centims. per second. The latest observations (1872) furnish the most probable value of v, 293×10^8 centims. per second.

Zoological Society, June 3.—Viscount Walden, F.R.S., president, in the chair. The secretary read a report on the additions that had been made to the Society's collection during the month of May. The following, among other objects, was exhibited:—The figure of a supposed new species of *Chelodina* from the Burnett River, Queensland.—A letter was read from Dr. George Bennett, F.Z.S., referring to the supposed existence of a species of Tree Kangaroo (*Dendrolagus*) in Northern Queensland, some such animal being apparently well known to the blacks of Cardwell.—A memoir was read by the Viscount Walden on the birds of the Philippine Archipelago, founded mainly on the recent collections of Dr. A. B. Meyer, but containing a complete account of all the known species of Philippine birds, and remarks on their geographical range. The total number of known Philippine species was estimated at 215, but a large number of the islands remained unexplored.—A paper was read by Sir Victor Brooke, Bart., F.Z.S., on the antelopes of the genus *Gazella*, of which 20 species or "persistent modifications," as the author preferred to call them, were recognisable. Sir Victor Brooke entered at full length into the questions connected with the present geographical distribution of the group, and its supposed descent from pliocene and miocene forms.—Mr. A. H. Garrod read a paper on the pterylosis and on some points in the anatomy of the Guácharo (*Steatornis caripensis*) and showed that this singular bird must be constituted a family *per se*, related in some respects to the Caprimulgidæ and their allied forms, and in other respects to the Owls (*Striges*).

Chemical Society, June 5.—Dr. Odling, F.R.S., president, in the chair.—Six communications were read before the society, the first being "On the dioxides of calcium and strontium," by Sir John Conroy, Bart., in which the author gave the method of preparation and properties of these substances.—Mr. T. Wells then described a new form of ozone generator which gives abundance of ozone and has the advantage of being easily constructed and not liable to be broken.—The other papers, which contained but little of general interest, were entitled "On the behaviour of acetamide with sodium alcohol," by W. N. Hartley; "On iodine monochloride," by J. B. Hannay; "On triferrous phosphide," by Dr. R. Schenk; and "On sulphur bromide," by J. B. Hannay.

Anthropological Institute, June 3.—Prof. Busk, F.R.S., president, in the chair.—The president exhibited and described a new apparatus for measuring, with ease and accuracy, the cubic capacity of skulls. Prof. Rolleston, while approving generally the method of Prof. Busk, differed with him in the nature of the material to be employed; he thought that sand was objectionable as being subject to hygrometric variation from which rape-seed was entirely free.—Prof. Robinson exhibited a remarkable bronze sword found in the bed of the Charwell, Oxfordshire, a bronze spear from Speen, near Newbury, and other implements of bronze and stone.—The president exhibited a series of stone implements from the Island of St. Vincent, West Indies, and Mr. A. W. Franks exhibited a bow and poisoned arrows lately used by the Modoc Indians, and found in Captain Jack's stronghold in the lava beds of Siskiyon County, California—The Rev. Dunbar I. Heath contributed Notes on a Mural Inscription, in large Samaritan characters, from Gaza, and claimed for it a higher antiquity than the date of the Moabite Stone.—Mr. H. Howorth read a paper entitled, "Strictures on Darwinism, part II., the Extinction of Types." The substitution of species involved two factors; 1st, the extinction of certain types; 2nd, the introduction of certain others. The paper dealt with the former factor only. Pre-Darwinian naturalists, and some of those who now oppose Darwin, have agreed that species become extinct through the operation of causes, such as climatic change, &c., acting *ab extra* and operating upon whole classes at once from without. Mr. Darwin has argued, on the other hand, that this extinction has arisen from the mutual struggles of individuals by which a certain strong and vigorous type has been evolved, and a certain weak and decrepit type extinguished; the difference between the two theories being that one relies upon external, the other upon internal causes for the explanation of the extinction of certain types. In the present paper the author examined the problem and attempted to show that the old view was the correct one. The paper passed in review the various elements that have gone to destroy types of life, changes in physical geography, changes in climate, epidemics, &c., and showed how the evidence of all of these supported the old view that extinction of type is the result of external influences, and not, as Mr. Darwin contends, of an internal struggle for existence. Prof Rolleston, Mr. Boyd Dawkins, and the president, combated the criticisms of the author.

Royal Microscopical Society, June 4.—Chas. Brooke, F.R.S., president, in the chair. The secretary read a paper by Mr. F. Kitton, of Norwich, descriptive of a new species of *Navicula*, with remarks on *Aulacodiscus formosus*, *Omphalopelta versicolor*, &c., collected in Peru by Captain Perry, of Liverpool; the paper was illustrated by specimens exhibited in the room.—A paper was also read by Mr. J. Stephenson, on the appearances of the inner and outer layers of *Coscinodiscus* when examined in bisulphide of carbon and in air, in which the author pointed out the different effects obtained by mounting the diatoms in media of different refrangibility, and showed the value of such comparisons in determining the nature of the markings, as well as the general structure. The paper was illustrated by a number of very carefully executed drawings by Mr. Charles Stewart, and by specimens exhibited under the microscope. The meetings of the society were adjourned until October.

Berlin

German Chemical Society, May 26.—A. W. Hofmann in the chair. Dr. Seligsohn investigating the origin of the oxalates deposited in the human body, has found that oxamide can be transformed into urea by ozone, and thinks therefore that oxamide is an intermediate product of digestion between the higher compounds of carbon and urea.—Dr. Rüdorff has found that saturated solutions of chloride of ammonium and nitrate of potassium are not influenced in their composition by adding either of these salts, while saturated solutions of nitrate of ammonium and chloride of potassium are changed in their composition by adding either one or the other to these solutions. In the same way behave most salts, so that the solution of one couple is influenced, while the other couple remains unchanged. But when K_2SO_4 and NH_4NO_3 are dissolved to saturation, this solution is influenced in the way described, and solutions of the opposite couple show likewise the alteration mentioned. These changes were proved by analyses and by determination of the changes of temperatures occurring. Self-evident conclusions offer with regard to the old question, if two salts in solution represent two or four different compounds.—C. Bulk spoke on the manufacture of arsenic acid from fuchsine-residues; by sublimation, as used in Elberfeld. The same chemist described a simple apparatus replacing spring-clamps in volumetric analysis. It consists of a piece of glass-rod inserted into an indiarubber tube. By pressing it cautiously drop after drop can be let out of the burette.—J. Grosshaus continued his speculation on the nature of chemical elements.—H. Vogel denied the existence of what Becquerel called

"rayons continuateurs." He explains the fact that photographic negatives, exposed for a few seconds to chemical light, and then to the red and yellow part of the spectrum, are acted upon by these rays, by admitting that during the first exposure chloride of silver is reduced only to the state of sub-chloride, which in its turn is acted upon by yellow light, and thus reduced to the metallic state. This explanation appears the more probable, as iodide and bromide of silver do not exhibit the same property, iodine and bromine forming but one compound with silver.—Julius Thomsen reported on the amount of heat yielded by mixing nitric acid and water. The result of his experiments he sums up as follows :—A diluted nitric or sulphuric acid, when further diluted with the same quantity of water it already contains, will yield the smallest amount of heat, when the molecular heat of the acid is equal to that of the water which is contained in it.—Henry Armstrong sent a summary of his researches on isomeric derivatives of phenole, most of which are familiar to the English public.—Heinrich Baumhauer published some remarks on the natural system of chemical elements, and the relations between atomic and specific weights.—F. Birlstein and A. Kullberg have found that α-dinitro-naphthaline treated with a mixture of nitric and sulphuric acids yields a new γ-trinitro-naphthaline fusing at 147°, while fuming nitric acid produces only the ordinary α-trinitro-naphthaline.—E. Mulder obtained a yellow solid combination by precipitating cyanamide with nitrate of silver. Its composition, CN_2Ag_2, leads the author to suppose cyanamide to be constituted according to the formula $C(NH)_2$ of carbodiimide.—R. Siemens submitted sulfo-acetic acid to the action of perchloride of phosphorus in order to investigate the chloride thus obtained as well as its reduction. To the former he gives the formula

$$\begin{array}{l} CHCl = SO_2Cl \\ | \\ COCl \end{array}$$

to the compound obtained from it by the action of tin and hydrochloric acid, the formula of thio-glycollic acid :

$$\begin{array}{l} CH_2 . SH \\ | \\ CO . OH \end{array} \quad \text{forming the lead-salt} \quad \left.\begin{array}{l} CH_2 . S \\ CO . O \end{array}\right\} Pb.$$

The chloride is decomposed by water into the body formerly described by Kolbe under the name of trichlor-methyl-sulforchloride, $CCl_3 . SO\ Cl$.

PARIS

Academy of Sciences, June 2.—M. de Quatrefages, president, in the chair.—The president announced the death of M. de Verneuil, *membre libre*, which occurred at Paris, May 29. —M. de Chevreul communicated the principal results of his researches on avic acid, which will shortly be published. The president presented the first part of the work on the crania of the human race upon which he and Dr. Hamy are engaged.—The following papers were read :—Note accompanying the presentation of a work on cellular anatomy and physiology, by M. Ch. Robin.—On the transit of Venus in 1882, by M. Puiseux.—Trial, during an eclipse of the sun, of the new spectroscopic method proposed for the observation of the next transit of Venus by Father Secchi. The method consists in placing a direct-vision system of prisms before the slit of the spectroscope, and then observing the interruption of the chromosphere by the dark body. The author compares observations by his method with those of Prof. Respigbi, published in the *Gazetta Officiale*, No. 145. Respighi saw the approach of the moon 21·9 secs. before Secchi, but Secchi saw the last contact 12·3 secs. before Respighi. The Rev. Father therefore suggests the use of the ordinary method (that used by Respighi) for first contact, and of his own for last. —A study of the action of the principal derivatives of amylic alcohol on polarised light, by MM. Pierre and Puchot.—Development of the freshwater algæ of the genus *Batrachospermum*, alternate generation; second note, by M. Sirodot.—On the nature and treatment of ear tumors (*oreillons*), by M. Bouchut.—On *Hylodes martinicencis*, by M. A. Bavay.—Documents relating to the short-period Comet Π, 1867, by Mr. Hind, M. Stephan, MM. Paul and Prosper Henry, M. André, and M. Baillaud. Communicated by M. Le Verrier.—Discovery of a new small planet by Mr. J. Henry, at Washington, U.S.A. — Displacement of a body subjected to four conditions, by M. Ribaucour.—On the action of the electric fluid on flames, liquids, and powders, second note, by M. Neyreneuf.—On the detection and estimation of plumbic sulphate in the lead chromates of commerce, by M. Duvillier. The author adds nitric acid and alcohol, the chromate is then reduced, the lead and cromic oxide are dissolved by the nitric acid, and the sulphate, if present, remains insoluble.—On the action of nitric acid on plumbic chromate, by the same author.—On a base isomeric with piperidin, and on the nitrated derivatives of the hydrocarbons of the formula $C_{2}mH_{2}m$, by M. H. Gal.—On the molecular rotation of gases, by M. Hinrichs.—Experimental researches on the pathogeny of infarctus, &c., by M. V. Feltz.—Observations on a recent note, by M. Rabuteau, relative to the toxic properties of the iodides of tetramethylammonium and tetramylammonium, by Messrs. A. Brown and Th. Fraser.—General results of the analysis of the Geyser springs of the island of San Miguel, Azores, by M. Fouqué. During the meeting an election to the place in the Mechanical section left vacant by the decease of M. Ch. Dupin, was held with the following results :—M. Resal, 31 votes; M. Bresse, 17; M. Boussinesq, 3; M. Haton de la Goupillière and M. Maurice Lévy, 1 each. M. Resal was accordingly declared duly elected.

DIARY

THURSDAY, JUNE 12.

ROYAL SOCIETY, at 4.—Election of Fellows.

SOCIETY OF ANTIQUARIES, at 8.30.—What Parts of Lincoln Cathedral are really of the Time of St. Hugh of Grenoble, A.D. 1192–1200? J. H. Parker, C.B.

MATHEMATICAL SOCIETY, at 8.—Some general Theorems relating to Vibrations: Hon. J. W. Strutt.—Invariant conditions of three and four concurrence of three Conics: J. J. Walker.—Locus of the point of concourse of tangents to an epicycloid inclined to each other at a constant angle: Prof. Wolstenholme.

FRIDAY, JUNE 13.

ASTRONOMICAL SOCIETY, at 8.

QUEKETT CLUB, at 8.

HORTICULTURAL SOCIETY, at 3.—Lecture.

SOCIETY OF ARTS, at 12.—Purchase of Railways by the State: Wm. Galt.

SATURDAY, JUNE 14.

ROYAL BOTANIC SOCIETY, at 3 45.

MONDAY, JUNE 16.

ASIATIC SOCIETY, at 3.

TUESDAY, JUNE 17.

ANTHROPOLOGICAL INSTITUTE, at 8.—The Ainos: Lieut. S C. Holland, R.N.—Account of an Interview with a Tribe of Bushmaos in South Africa: G. W. Stow.—Specimens of Native Australian Languages: Andrew Mackenzie.

ZOOLOGICAL SOCIETY, at 8.30.—On the Osteology of the Maltese fossil Elephants: Dr. A. Leith Adams, F.R.S.—On the Geographical Distribution of Asiatic Birds: H. J. Elwes.

STATISTICAL SOCIETY, at 7.45.

WEDNESDAY, JUNE 18.

METEOROLOGICAL SOCIETY, at 7.—On some Results of Temperature Observations at Durham: John J. Plummer.—On the Meteorology of New Zealand, 1872: C. R. Marten.—On the Climate of Vancouver Island: Robert H. Scott, F.R.S.—Meteorological Observations at Zi-Ka-Wei, near Shanghai: Rev. A. M. Colombel and Rev. S. J. Perry.—Notes on the Connection between Colliery Explosions and Weather: R. H. Scott, F.R.S., and Wm. Galloway.—Annual General Meeting.

HORTICULTURAL SOCIETY.—Exhibition.

THURSDAY, JUNE 19.

ROYAL SOCIETY, at 8.30.

SOCIETY OF ANTIQUARIES, at 8.30.

LINNEAN SOCIETY, at 8.

CHEMICAL SOCIETY, at 8.—On the Influence of Pressure upon Fermentation. Part II.: Horace Brown.—Researches on the Action of the Copper-Zinc Couple on Organic Bodies, III., and on Normal and Iso-Propyl Iodides: Dr. J. H. Gladstone and A. Tribe.—On Cymenes from different sources optically considered: Dr. J. H. Gladstone.—On the Action of Bromine on Alizarine: W. H. Perkin.—On some Decompositions and Oxidation Products of Morphine and Codeine Derivatives: G. L. Mayer and Dr. C R. A. Wright.—On the Decomposition of Tricalcic Phosphate by Water: R. Warrington.—On a new Tellurium Mineral, with Notes on a Systematic Mineralogical Nomenclature: J. B. Hannay.—Communications from the Laboratory of the London Institution, No. XII;—On New Derivatives of Cresol: Dr. H. E. Armstrong and C. L. Field.

CONTENTS

THURSDAY, JUNE 19, 1873

JEREMIAH HORROX*

II.

IT is now time to pass to the particular incident which has immortalised the name of Horrox, his observation of the transit of Venus over the sun's disc on November 24, 1639 (O.S.) It would have been sufficient for his renown to have been the first witness of the phenomenon, but he had in addition the honour of supplying an omission of Kepler's, who had indeed predicted the transit of 1631, but had failed to point out the occurrence of another eight years subsequently. The transit of 1631 had not been observed owing to its occurrence at night, and that of 1639 had been foreseen by no one save Horrox, and was watched by no one but himself and his friend Crabtree, whom he apprised of the forthcoming event in a letter dated on the October 26 previous.

We borrow Mr. Whatton's account of the observation ("Life of Jeremiah Horrox," pp. 44—46).

"After having deliberated on the best method of making the observation, he determined to admit the sun's image into a dark room, through a telescope properly adjusted for the purpose, instead of receiving it through a hole in the shutter merely, as recommended by Kepler. He considered that by the latter method the delineation would not be so perfect, unless it were taken at a greater distance from the aperture than the narrowness of his apartment would allow; neither was it likely that the diameter of Venus would be so well defined; whereas his telescope, through which he had often observed the solar spots, would enable him to ascertain the diameter of the planet, and to divide the sun's limb with considerable accuracy. Accordingly, having described a circle of about six inches diameter upon a piece of paper, he divided its circumference into 360°, and its diameter into 120 equal parts. . . When the proper time came, he adjusted his apparatus so that the image of the sun should be transmitted perpendicularly to the paper, and exactly fill the circle he had described. From his own calculations he had no reason to expect that the transit would take place, at the earliest, before three o'clock in the afternoon of the 24th, but as it appeared from the tables of others that it might occur somewhat sooner, in order to avoid the chance of disappointment, he began to observe about mid-day on the 23rd. Having continued to watch with unremitting care for upwards of four-and-twenty hours, excepting during certain intervals of the next day when, as he tells us, he was called away by business of the highest importance, which could not with propriety be neglected, he was at length rewarded for his anxiety and trouble by seeing a large dark round spot enter upon the disc of light."

The "business of the highest importance" was undoubtedly divine service, the transit having taken place on a Sunday. Most modern astronomers of Horrox's profession would, no doubt, have considered the claims of science paramount on an occasion like this. Horrox, in accordance with the feeling of his day, judged otherwise, and when all the circumstances of the case are taken into account, his sacrifice on behalf of what he esteemed a higher duty, must be regarded as an act of extraordinary heroism. He had, it is true, almost convinced himself that the transit could not occur until the afternoon, but even this anticipation was a proof of courageous reliance on his own judgment, being founded on his correction of Kepler's Rudolphine tables, according to the data supplied by which it should have occurred at 8.8 A.M. The phenomenon was also observed by Crabtree, but less perfectly, owing to the cloudy state of the atmosphere at Manchester. A letter from Crabtree on the subject to another north-country astronomer, Gascoigne, contains the remarkable expression, "I do believe there are as rare inventions as Galileo's telescope yet undiscovered."

Horrox did not remain at Hoole much above six months after this great achievement. In July, 1640, we find him again at Toxteth, which he never afterwards left. He must, accordingly, have resigned his curacy, on what account is unknown, as is also the precise nature of his subsequent avocations. We only gather from his correspondence that his affairs were in a very unsettled state, that the duration of his stay at Toxteth was uncertain, and that he was continually called from home. From his complaints of the impossibility of prosecuting his astronomical researches, one would almost surmise that his occupation was nocturnal, especially as he found time for the observations on the tides already referred to. His sustained enthusiasm for astronomy, as well as the generosity of his temper, is touchingly shown in a letter congratulating his friend Crabtree on the success of some observations reported by him: "Your letter alone," he says, "has enough and more than enough to transport beyond all bounds a soul more master of itself than mine. My emotion and gladness are such as you will more easily understand than I express." After several postponements, he eventually fixes January 4, 1641, for a visit to Broughton, but the intention was frustrated by his sudden death on the morning of the preceding day. We learn this from an endorsement by Crabtree, who gives no particulars respecting the cause of death, and who himself, according to Dr. Wallis, only survived his friend for an extremely short period.

We are indebted to Crabtree for the preservation of Horrox's extant papers, those only having escaped destruction which were obtained by him after the writer's death. Of the remainder, part were destroyed during the Civil Wars; part carried to Ireland by Horrox's brother Jonas, who appears to have shared his scientific tastes, and there lost; another portion, after having aided in the compilation of Jeremiah Shakerley's astronomical tables, was destroyed in the great fire of 1666. Crabtree's MSS., happily including the autograph of the "Venus in Sole visa," were purchased after his death by Dr. Worthington, of Emmanuel College, subsequently Vicar of Hackney, and a copy of the "Venus," lent by him to the astronomer Hartlib, having found its way into the hands of Hevelius, was published by the latter in 1662. The Royal Society, just instituted in England, immediately took cognizance of the remainder of the MSS., and having obtained these from Dr. Worthington, placed them in the hands of Dr. Wallis, Professor of Geometry at Oxford, whose Latin translation was ultimately published in 1674. By a judicious arrangement of his materials he was enabled to digest these into a perfect treatise, to which he gave the title of "Astronomia Kepleriana Defensa et Promota." To this he added a translation of the scientific portion of

* Continued from p. 117.

Horrox's letters to Crabtree, to which we are indebted for most of our scanty biographical information. An inspection of the originals, should these have been preserved would probably contribute much to clear up doubtful points, and to complete our conception of Horrox's intellectual character. The main outlines of the latter, however, are sufficiently apparent. They comprise a marvellous patience and persistency, combined with wide-reaching activity, a philosophical faculty for generalisation, ambition, enthusiasm, and self-confidence. The versatility of his attainments is attested by the composition of his "Venus" in Latin, by the quotations in his letters from Horace and Juvenal, and by his reference to Raleigh's "History of the World." Of his restless energy and fertility of resource we have proof in the promptitude with which, when debarred from his favourite pursuit, he turns to the investigation of the tides. His grasp of general principles is displayed, among other passages, by a remarkable one in which he speaks of the possibility of illustrating the elliptic orbits of the planets by terrestrial analogies. "To which method of confirmation Kepler is always partial, and most justly, inasmuch as Nature throughout the universe is One, and the general harmony of creation causes the lesser things to be examples of the greater, as the revolution of the moon around the earth is an emblem or imitation of that of the stars around the sun." We have already had occasion to appreciate his enthusiasm; and the self-reliance usually associated with enthusiasm is powerfully evinced in another letter exhorting Crabtree to undertake, in conjunction with him, the preparation of a new set of astronomical tables. From some expressions in this it may be conjectured that he felt hurt at the ignorant comments of his neighbours, and his resentment against his false guide Lansberg, which occasionally transgresses the limits of what would be considered courtesy at the present day, is another indication of a sensitive spirit. When we add to these traits the self-denial manifested on occasion of the transit, and in the temporary renunciation of his astronomical researches in deference to the claims, as seems probable, of his family, we must recognise in Horrox no mere man of science, but a distinct individuality of singular force and attractiveness. His precise place in the scientific world must be left to astronomers to determine; it requires, however, no special knowledge of the science to apprehend that the obscure youth who, under every disadvantage, was able to correct Kepler, might, if only he could have continued at Cambridge, very probably have rivalled him. In him England lost the promise of an astronomer of the first class, which loss, like many a similar one, would have remained absolutely unknown, but for the fortunate conjunction of his name with a phenomenon of regular recurrence and universal interest. If the commemoration of his great achievement cannot be equally universal, it should at least transcend merely local limits. Local patriotism has done its part well; an appropriate memorial has been erected in the church at Hoole, and we are exceedingly indebted to Mr. Whatton for his intelligent memoir and valuable translation of the "Venus in Sole visa." More, however, is demanded, and it would redound to the credit of Horrox's countrymen if, on the December day of 1874, when English watchers scan the skies of another hemisphere for the transit of Venus, Englishmen at home were found dedicating a national monument to the first observer of the phenomenon in this.

JAGOR'S "PHILIPPINE ISLANDS"

Reisen in den Philippinen, von F. Jagor. Mit zahlreichen Abbildungen und einer Karte. (Berlin: Weidmannsche Buchhandlung. 1873.)

THE increasing importance which the Philippines are assuming in both English and American commerce, the comparative insufficiency of the information we possess concerning them, and the beauty and productiveness of nearly the whole region, amply justify the ardour with which the author of this volume has devoted himself to a thorough exploration of the group, and an exhaustive study of every feature of interest appertaining to its component islands and their population. In this very interesting and acceptable work he has given to the world the results of his observation and inquiries, and of these it may be said that, while in point of extent and variety they are sufficiently comprehensive to embrace within their limits every subject of interest or of practical importance to which we should expect to find a place assigned in a book of travels having any pretensions to completeness, they bear the evident impress of the patient, laborious research, and the careful examination and weighing of facts, for which his countrymen are famous.

M. Jagor can hardly be said to be a recent traveller in these islands. His journey through them was made in the years 1859 and 1860, but unforeseen circumstances put a sudden stop to it; and though fully intending to resume it at a later day, that purpose has not yet been accomplished. Although it must be admitted, therefore, that his work does not make its appearance with all that absolute freshness about it to which we are accustomed in these days of ocean steam-navigation, the apparently long interval which has elapsed since his visit has been profitably turned to account by him in the careful study of an immense mass of materials accumulated by himself during his stay, or which he obtained through the Spanish Colonial Minister, or found in the great national libraries of London and Berlin, including a few bulky monkish chronicles, the perusal of which last was a work both long and tedious. In the vast labour incident to the extraction from these various sources of their most important and most interesting details, he has been sustained by a conviction that his subject was worthy of it. He has felt, as he tells us, that few countries in the whole world are so little known or so seldom visited as the Philippines, while none present more agreeable attractions for the traveller, or have been more profusely endowed by the hand of Nature, or contain a larger store of neglected treasure for the natural historian. So strong and so abiding is his faith on this last point, he gravely assures his readers, that even poor travellers would amply cover the cost of their journey by the sale of their collections. Without going so far as to endorse this suggestion in its full and entire significance, it is nevertheless true that the descriptions here given constitute, in the aggregate, a picture of marvellous natural

wealth, of which it is on many accounts desirable that modern enterprise should have full and trustworthy information.

The travels recorded in this volume extended through the greater portion, certainly the most important and interesting, of the Spanish Philippines. Manila was the starting point. The author first made a short excursion northwards, thence into the province of Bulacan, and returning to Manila ascended the river Pasig, at the mouth of which it stands, to the great lake of Bay, crossing which he made several journeys into the province of Laguna. Returning thence to Manila, he crossed its magnificent bay, spacious enough to hold all the navies of the world, and proceeding by sea along the deeply indented southern coast of the great island of Luzon, and traversing the Straits of San Bernardino, landed at Albay, the chief town of the large insular province of the same name. From this point he made an excursion into the extreme southern districts of the island, visiting the great volcano of Balusan on his way, and returning to Albay, started thence in a north-westerly direction on a journey through southern Camarines. On this journey many natural features of the highest interest engaged his attention, and notably the great volcanoes of Mayon and Yriga, the Bateo Lake, and the remarkable siliceous wells near Tibi, with the great flat cones called the "white" and the "red," between which they lie—the whole of this district presenting one of the finest examples of calcareous depositions, in various states of advancement, in the whole world. Returning westwards to his main route, he reached Meroce Caceres, near the confines of northern and southern Camarines, and from this point made a considerable digression eastwards, for the purpose of visiting the vast volcano Ysarog, of which, and of the inhabitants of the region, he has given a full and highly interesting description. Again returning to his main route, he arrived at Cabusao on the Bay of San Miguel, and from this point, partly by land and partly by coasting, he explored about forty miles of the eastern coast of this portion of North Camarines, making occasional journeys inland where the prospect of reward seemed to invite attention. Returning to Albay, he embarked at that place for the next important island in this remarkable archipelago, Samar. There he landed at the north-eastern point, and crossing in a south-westerly direction to its western coast, coasted some twenty or thirty miles southwards to Carthalogan. From this place he traversed the centre of the island, and descending the river Ulut, reached the eastern side. He next coasted to its south-eastern extremity, and thence returned westwards, landing at Tacloban, the chief town of the closely adjacent island of Leyte, on which he made a journey many miles to the south. He then traversed the narrow Straits of San Francisco, which separate Samar and Leyte, visiting the ancient rock sepulchres in which the inhabitants of Bisay and some other localities interred the remains of their heroes and their elders. Continuing his return journey by sea, he again reached Manila, after having visited some minor islands, and obtained interesting information relative to them.

It would be vain to attempt, within the narrow limits of space available for our present purpose, anything like a substantial account of the innumerable matters of interest, with which M. Jagor's book deals. The mere enumeration of them would very considerably extend the proportions of an ordinary review, and there are many, very many, which present attractions of the highest order for the geographer, the geologist, the ethnologist, the naturalist, and others who interest themselves in certain special branches of modern science. All that can be done is to indicate a few of the more striking portions of the work, by which its character and completeness may be judged of, referring to the work itself—which we venture to think would well repay translation—those specially interested in its subject.

In his first chapter, the author makes some remarks on the situations of the group, and describes a few amusing circumstances which resulted from the ignorance of Magellan and his followers, of the difference of time depending upon difference of longitude. Such was the injudicious commercial policy of the Spaniards in those dependencies, that the intercourse between them and the Mother Country "was limited to the conveyance of officials and ecclesiastics, and their ordinary necessaries—provisions, wine, and other beverages (Caldos), and, a few French romances excepted, some very dull books—histories of Saints and other similar matters." As regards the aspect of Manila, despite the glowing descriptions of it given by many travellers, the author experienced considerable disappointment; his first impressions being received at a most unfavourable moment, since he landed towards the close of the dry season. The account he gives of the state of society in Manila and its suburbs is anything but inviting. "Life in the city proper can scarcely be agreeable: pride, envy, place-hunting, caste-hatred, are the order of the day. The Spaniards deem themselves superior to their Creoles, who, in their turn, reproach them with coming to the colony only to eat their fill. The same hatred and the same grudge exist between the whites and the half-castes." It appears that cock-fighting is the great pastime of the population. The social, political, and commercial condition of the colony is fully developed in the first four chapters of the book, and in connection with this part of the subject the author ventures on a few reflections on the future of the Philippines. He says:—"Now that the Eastern shores of the Pacific are at length becoming populated, and with unparalleled rapidity are advancing towards their great future, the Philippines can no longer remain in the exclusion which has hitherto been their lot; because, for the western coast of America, there is certainly no tropical Asiatic country so favourably situated; while as regards Australia, it is only in certain relations that Dutch India can dispute precedence with them. Their trade with China, on the contrary, whose staple-market Manila originally was, as also that with the western countries of Asia lying nearer to the ports of the Atlantic, they must for ever renounce."

The fifth chapter is devoted to a very clear and comprehensive exposition of the geography and the meteorology of the Archipelago, the political divisions of the Islands, their various populations, and the languages spoken in them.

On his first journey into the province of Bulacan, the author was much struck with the fertility of the soil, a subject upon which he has a good deal to say, as also

upon the contrivances used for fishing. There, too, as in other portions of his route, he became familiar with the ways of Spanish priests, and formed his experiences of native hospitality, besides learning something of the system of wholesale plunder which is carried on almost with impunity, on sea and on land, in this as in all other portions of the islands, where it is likely to pay. It appears, from the author's statements, that piracy is frequent on the coast, and that the country is likewise exposed to gangs of lawless marauders, against whom the Government is almost powerless, while the people are generally deprived of firearms, or, when provided with them, don't know how to use them. Occasionally they make descents upon the land, plundering wherever they go, often accompanying their rapacity with deeds of violence, even murder, and constantly carrying away their victims as prisoners.

Of the land and sea journeys of M. Jagor, generally, it may be said that they are full of incident, and that he never allows anything to escape his notice which may appear to him to be likely to have interest in the eyes of Europeans. From volcanic eruptions to the many odd incidents that presented themselves to him on his journey, nothing is unworthy of his attention, nor beyond his graphic power. His style is at once quiet, simple, and effective, and will delight every reader of German, by the ease with which it portrays the grandest or the most simple objects. He is always deeply impressed with the grandeur of the scenery through which his path lies, heightened as it often is by the beauty and luxuriance of tropical vegetation, and the majesty of primæval forests which extend their dense masses to the sea-margin. The natural productions of the country—animal, mineral, and vegetable—are the subject of copious mention ; and in connection with this part of the subject he has been at great pains to examine for himself, and put on record, the industrial and Governmental conditions under which all this mineral and other wealth is, or rather is not, made available for commerce. This is remarkably seen in his chapters on Manila hemp, and on the Government tobacco monopoly.

One of the most curious and interesting portions of the whole book is the twentieth chapter, which describes some remarkable antiquities in the narrow San Francisco strait, a locality whose picturesqueness the author extols, questioning much "whether the ocean anywhere laves a spot of such rich and peculiar beauty." The substance of this chapter, together with a few other portions of the work, has already appeared in Bastian and Hartmann's "Zeitschrift für Ethnologie." The remains referred to are certain ancient sarcophagi found in cavities in a series of marble-like rocks situated near the eastern entrance to the straits, and in a few other remarkable localities. These rocks rise out at sea to a height of a hundred feet. Their summits are dome-shaped, and their bases are much worn by the action of the sea. In these cavities the ancient Pintados, a race of tattooed Indians, and some other natives of the Archipelago, deposited the remains of their wives and elders as before adverted to. They placed them in carefully closed coffins along with the objects which in life they deemed most precious. Slaves were sacrificed at their burial, in order that they might not be without attendants in the next world. These spots were regarded with superstitious awe by the natives, who believed them to be haunted. A young Spanish clergyman led an expedition to some of the caves, and after some religious ceremonies, wrecked the coffins, and turned their contents into the sea. The superstition still lingers about the rocks, although much weakened. The author had some difficulty in finding men resolute enough to accompany him on an expedition having a somewhat different object in view, that of bringing away some of the relics. He succeeded, however, and the trophies were deposited by him in the Zoological Museum of Berlin University.

Profs. Roth and Virchow have contributed to the scientific portion of the book—the former dealing minutely with the geology of the group, the latter with its ancient and its more recent inhabitants. A copious appendix contains articles treating of the Islands under every possible aspect—historical, antiquarian, commercial, and governmental. The book is handsomely got up, and is printed in Roman characters, now getting more and more into use in Germany, and it is enriched with numerous admirably executed engravings, in various styles, from drawings made by the author on the spot, or obtained by him during his journey. A beautifully executed map is added, and the whole volume may be said to be an important and valuable contribution to the literature of its class.

MILLER'S ROMANCE OF ASTRONOMY

The Romance of Astronomy. By R. Kalley Miller, M.A. (Macmillan & Co., 1873.)

IT is in days of strongly marked utilitarianism, when so much is brought into the market that was never intended to go there, and so much of what is there is unfortunately rated at its marketable value only, that corresponding efforts should be made, by those who have the welfare of society at heart, to maintain the due balance of the human intellect by the cultivation of its imaginative faculty. It is here that poetry affords the noblest aid ; and even the profusion of modern fiction may be looked upon by the philanthropist with less regret ; if only moderately sensible and well-guided, it may lend important assistance in obviating that degeneration which would be the sure result of undue and excessive mental development in any one direction.

The work now before us, a curious little book with a curious title, may in this view of things not be without its value. It is a reprint and enlargement of some popular lectures which appeared in the *Light Blue;* and the author tells us that his object "has not been so much to instruct as to entertain, and possibly in some cases to inspire a taste which might lead to the further prosecution of a most fascinating study ; and this will be his apology for passing over many important parts of the subject, and simply selecting a few points here and there which seem to afford scope for striking or amusing amplification." And in pursuance of this design, he brings before us a series of speculations as to the possible condition of other worlds, where fancy is allowed as full a range as the most romantic of readers can desire. As an amusing instance of his peculiar vein, the following passage may be cited : "The part of the moon which appears bright to us must

have any moisture which it may contain dried up by his (the sun's) vertical beams; while on the other, or dark side, the ground must be frozen hard to the depth of several feet, the mountains covered with glaciers, and the seas blocked up with icebergs. At the very margin between the two hemispheres there will be a narrow temperate zone, which will of course move round the moon, as the latter turns round its axis and presents its different faces successively to the sun; and the only way in which we can see that life could be supported with comfort at the moon (supposing the atmospherical difficulty surmounted) would be by moving constantly round it, so as to keep always in this temperate zone. A queer Noah's Ark-like sight it would be to see the whole inhabitants of the moon, side by side, in a huge procession extending from pole to pole, and hurrying quickly round it at the rate of ten miles an hour—some riding, some driving, and some travelling in slow railway trains; beasts, wild and tame, galloping by their side, and all the birds of heaven flying along over their heads!" The chapter, too, on Astrology, is of a very diverting character, and above all, Zadkiel's horoscope of the heir-apparent to the British throne.

In the face of such an avowal as the author has made, anything like rigidity of criticism would be out of place: but we cannot help expressing regret that his always pleasing and often beautifully written descriptions should occasionally require the support of a more accurate statement of facts. We have so much respect for his ability, and admiration more especially for the high tone of his principle, as to hope that the book may reach a second edition: but in that case we should hope for the removal of several blemishes which it might seem invidious to point out, but which will be obvious to the scientific reader.

T. W. W.

OUR BOOK SHELF

Proceedings of the Berwickshire Naturalists' Club, Vol. vi. No. 4.

THIS is, we believe, the oldest field-club in existence, and has all along been one of the most efficient and most prosperous so far as numbers and funds are concerned. Its publications, moreover, are already numerous, and contain much valuable material for the natural history, archæology, and antiquities of Berwickshire. There must be already a vast amount of material shut up in the transactions of the now numerous local societies, of the greatest value in reference to the natural history of this country and to students of biology generally, but almost inaccessible except to the members of the various societies. It is a pity that some means could not be devised for bringing the most important contributions to local natural history, in its widest sense, together in some systematised form, so that they could be readily referred to and made available to students at large. Sir Walter Elliot refers to this point in his able address on Provincial Scientific Societies, and it is to be hoped that the Committee appointed by the British Association will give it their consideration. Prefixed to the Proceedings before us is the President's, the Rev. F. R. Simpson's, address, which is wholly occupied with an interesting account of the various meetings of the club during the summer of 1872. For this society is purely a field club, meeting only during the summer months, to explore some of the rich vales of Berwickshire or stretch their limbs over some of the bonny Cheviot fells, gathering rich stores of varied knowledge, and finding a glorious appetite for the substantial dinner which usually winds up the meetings. One of the longest and most interesting papers is by one of the secretaries, Mr. James Hardy, "On Langleyford Vale and the Cheviots," being a sort of survey of the district between Wooler and the base of Cheviot, and containing a wonderful amount of information on the geology, botany, zoology, and especially the prehistoric antiquities of the district. Mr. Hardy also contributes some valuable entomological lists to this part of the Proceedings, and various antiquarian papers; while Mr. Robert Hislop has a list of the rarer Coleoptera occurring chiefly in the parish of Nenthorn. Sir Walter Elliot contributes a list of the diurnal birds of prey hitherto found within the club's limits. There are many other valuable papers including a memoir of the late Dr. William Baird, F.R.S., one of the founders of this old society, appended to which is a list of his many writings. There are two very well executed plates of flint implements and a sculptured stone, and a fine portrait of the Club's late Secretary, Mr. George Tate.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Dr. Bastian's Turnip-Cheese Experiments

IN a former communication* I gave an account of a series of experiments by Dr. Bastian, in which it was established that, "by following his directions, infusions can be prepared which are not deprived by an ebullition of from five to ten minutes of the faculty of undergoing those chemical changes which are characterised by the presence of swarms of Bacteria, and that the development of these organisms can proceed with the greatest activity in hermetically sealed glass vessels, from which almost the whole of the air has been expelled by boiling."

In the first paragraph of that paper I adverted to the importance in every experimental inquiry of defining as completely as possible the method by which any given result can be attained. With this consideration in view, I now propose to give an account of additional experiments, made chiefly for the purpose of elucidating the influence of slight variations of temperature on the result. To guard against the possibility of mistake, it may not be unadvisable to remark that, whereas in the experiments previously reported upon, I took no part, excepting as a witness, I am exclusively answerable for those now to be recorded.

Certain particulars in Dr. Bastian's method have been objected to as possible sources of uncertainty. Thus it has been suggested that when a flask, of which the neck has been drawn out to a capillary orifice, is boiled even for ten minutes over a lamp, it is not certain that the whole of the liquid contained in it is heated to the temperature of boiling; and again, that when the lamp is withdrawn in the act of closing the capillary orifice, germs may enter from without. Although I do not attach much importance to either of these objections, I have modified Dr. Bastian's method, so as to render them inapplicable. The modification, however, applies exclusively to the mode of heating the hermetically sealed flasks. As regards the preparation of the liquid, I have in no respects departed from his instructions.

The liquid is prepared by simmering slices of peeled turnip in a beaker containing about a pint of distilled water. The acid infusion thus obtained, is, if necessary, concentrated by evaporation until it possesses a specific gravity of from 1018 to 1020. It is then filtered and neutralised with sodic carbonate. A little Cheddar cheese is rubbed up with a few drachms of the liquid in a mortar, and the mixture strained through calico. By adding the strained product to the rest of the infusion a turbid liquid is obtained, in every drop of which particles of cheese can be detected by the microscope, although there are scarcely any of a sufficient size to be distinguished by the naked eye.

In the first four sets of experiments retorts were used, in the others flasks. In either case they were charged with the liquid of which the preparation has just been described (their necks having been previously drawn out), boiled over a spirit lamp, and sealed hermetically by directing the flame of the gas blow-

* See NATURE, vol. viii. p. 180.

pipe on the orifice at the same moment that the lamp was withdrawn. The experiments of the first two sets may be regarded merely as more exact repetitions of the former ones. Their results are confirmatory of those previously obtained. In the others the flasks were subjected to the temperature of ebullition under pressures exceeding that of the atmosphere. Although the excess of temperature in no case exceeded two degrees and a half, it will be seen that it exercised a decided influence on the results.

The pressures employed varied from one-tenth of an inch to three inches of mercury. According to * Wüllner's table, founded on those of Régnault and Magnus, an excess of 27 63 mill. over the normal pressure (760 mill.), determines an increase of 1° C. in the temperature of boiling, so that here 0°·924 C. corresponds to one inch of pressure. Similarly we have 0° 88 for the second inch, and 0°·873 for the third inch. In other words 100°·92 C. is the temperature of ebullition at one inch, 101°·81 at two inches, 102°·68 at three inches. In describing the experiments I use the expression "turnip-cheese" liquid to denote the neutral infusion of turnip with cheese of which the preparation has been given above; and in recording the results the words barren and pregnant are employed to express the absence or presence of living Bacteria. In any liquid which has been kept five days at the temperature of fermentation there is no difficulty in determining in which of these two conditions it is, for if Bacteria are present at all they are present in such numbers that every field is crowded with them. Bodies which appear to be dead Bacteria are met with here and there in every specimen. They are as numerous in liquids examined immediately after prolonged boiling as in others. They are probably derived from the cheese.

The retorts or flasks were examined after periods varying from three to six days, during which they were kept in the warm chamber at 32° C. Each was tested by observing that when the point of the blow-pipe flame was directed on the neck of the flask the softened part was first drawn in and then gave way with a loud crack.

With these preliminary observations I proceed to give an account of the experiments.

March 1.—Two retorts were charged with turnip-cheese liquid of which the specific gravity was 1017·2, each retort receiving 25 c.c. One was immersed in boiling water in a saucepan for an hour and then placed in the warm chamber: the other was placed in the chamber at once, *i.e.* immediately after it was boiled and closed hermetically. Both were examined on the 4th. The first was barren, the second pregnant.

March 4.—Nine retorts were charged with cheese-turnip liquid, sp. gr. 1020. Each contained 35 c.c. After having been boiled and closed hermetically, eight of the retorts were successively subjected in couples to the temperature of boiling water in a digester.

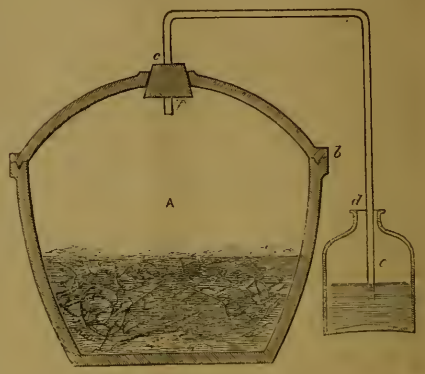
The construction of the digester was such that during the ebullition, which in each case was continued for 15 minutes, steam escaped through various narrow openings. The heating of the retorts was accomplished in four processes, each couple of retorts being heated separately and the valve differently weighted in different cases. Thus in three ebullitions the weights employed were severally 2 lbs., 4 lbs., and 6 lbs., while in the fourth, no weight was added to that of the valve itself. The experiment was planned in this way in order that the influence of pressure might be observed, but in carrying out, it was at once observed that with this view the method was a futile one, for steam escaped so readily in each experiment through the valve that there could be no doubt that all the retorts were in reality subjected to the same temperature, *i.e.* to the ordinary temperature of ebullition. The ninth retort was treated in the same way as the others with this exception, that the ebullition was continued for an hour, the valve remaining open.

The liquids were examined March 10. Of the eight which were immersed in boiling water for 15 minutes, all were pregnant. The ninth retort was barren.

March 13.—Six retorts were charged with turnip-cheese liquid, sp. gr. 1018, after which they were boiled and closed hermetically as before. The retorts were immersed in boiling water as previously, but the experiment was so planned that the pressure under which ebullition took place could be increased at will. The arrangement of the apparatus will be best understood from the diagram. A is a strong iron pot (or digester), the lid of which fits it by a grooved joint *b*. To render the joint air-tight, the groove is filled with white lead before fitting on the lid, which is then tightly wedged into its place. The valve having been removed, the orifice of the digester is stopped by a vulcanite plug, *c*, through which the long tube passes. This forms a perfect joint, for the greater the internal pressure, the more tightly it fits. The end of the tube dips into mercury contained in a large bottle, *e*, and is retained in its place by a holder at *d*, not shown in the diagram. The pot is half filled with water containing a quantity of hay, among which the flasks are arranged. It is supported on a triangle and heated by a Bunsen's burner, the mercury bottle being raised on blocks until the end of the tube dips to about the right depth under the surface of the metal. A more exact adjustment is attained by means of the holder already mentioned.

* Wüllner, Lehrbuch der Experimentalphysik, B. III., p. 559.

In this apparatus the six retorts were subjected to the temperature of ebullition under various pressures, viz., two under a pressure of three inches, two under a pressure of four inches,



and two under a pressure of two inches. The period of heating in each case was fifteen minutes. All of the flasks were placed, after heating, in the warm chamber at 32° C., and were examined March 18. All were barren.

March 22.—Four retorts were charged with turnip-cheese liquid, sp. gr. 1019, each receiving 50 c.c. Of these two were heated in the apparatus at the temperature of ebullition under a pressure of one inch, the other two under a pressure of half an inch. Of each couple one was accidentally broken. Both the remaining ones were examined March 27, and found to be barren.

May 7.—Nine flasks were charged with turnip-cheese liquid, sp. gr. 1019, each flask containing 50 c.c. Of these, four were subjected to the temperature of water boiling under pressure of one inch of mercury for thirty minutes, and four for the same period to the temperature of ebullition under one-tenth of an inch. They were examined May 12. Of each set one contained Bacteria, the rest being barren. The liquid in the other flask, which was simply boiled, and closed while boiling, had an offensive smell, and contained much scum.

May 22.—Thirteen flasks were charged with turnip-cheese liquid, sp. gr. 1019·5. Of these six were subjected to the temperature of ebullition at three inches, and six to the ordinary temparature of boiling water. The remaining flask, after having been closed hermetically in ebullition in the same way as the rest, was placed with them in the warm chamber. All the flasks were examined May 26. All the six flasks of the first set were barren. Of the six flasks of the second set four were barren, the others contained innumerable living Bacteria. The liquid in the other flask was offensive, and contained masses of bacterial scum.

After the examination several of the flasks containing barren liquids, particularly those which had been heated under pressure, were replaced in the warm chamber. Some of them were simply closed hermetically (the liquid having been taken for examination by means of a freshly drawn out capillary tube), others were closed after the introduction of a drop of distilled water. On opening these flasks several days afterwards, it was found that those which had been impregnated by the addition of

the distilled water were full of Bacteria, the others remaining barren. This was done to show that the liquid, although deprived of its power of germination, is as capable as before of supporting the life of Bacteria

The results of the preceding experiments may be summed up as follows:—In sixteen experiments the liquids were subjected to the temperature of boiling at the normal pressure; of these, eight were heated for 15 minutes, and all bred Bacteria; six were heated for 30 minutes, of which two bred Bacteria; two for an hour, both of which were barren.

Of ten subjected to the temperature of ebullition at pressures not exceeding one inch, eight were barren. Both the liquids which were found to be pregnant had been heated for 30 minutes, one under a pressure of one-tenth of an inch, the other of one inch.

In the twelve experiments in which the liquids were heated under pressures exceeding one inch, all were barren, although half of them were subjected to that temperature for only 15 minutes.

It is unnecessary for me to draw any inferences from the preceding experiments; it may not, however, be superfluous to point out that, although all the flasks heated above 101° C. remained sterile, this fact affords no ground for concluding that any definite relation exists between that precise temperature and the destruction of the germinating power of the liquid in question. All that has been shown is that the *chance* that such a liquid will breed Bacteria is diminished either by slightly increasing the temperature to which it is heated, or increasing the duration of the heating. Thus it appears to me quite probable that if a sufficiently large number of flasks were heated even to 102° C., some of them would still be found to be pregnant.

University Coll., London, June 7 J. BURDON SANDERSON

Fertilisation of the Pansy.—Ground Ivy

THERE is one further point in the structure of *Viola tricolor* which is not mentioned by Mr. Bennett or by Mr. Hart, but which seems to confirm the theory of the former gentleman that *V. tricolor*, as distinguished from most other Violas, is fertilised by a small insect such as Thrips instead of by the proboscis of larger insects.

Before I saw Mr. Bennett's paper, my attention had been called by Miss Dowson to the fact that whereas in the Sweet and Dog Violets, the circle of anthers presses close to the style all round, there is in *V. tricolor* an opening between the two appendaged stamens. The use of this opening will evidently be to allow the small creature to enter in and crawl down the stamen to the nectary at the end of the appendage. This structure may be also seen in *V. cornuta*, which seems to be fertilised in the same way. In *V. tricolor* the opening is exactly opposite to the black streak, or guide-post, as Mr. Bennett has termed it. In *V. cornuta*, although this black mark is not so evident, there is a distinct triangular mark pointing downwards exposed by the opening of the stamens. On each side of the style are two sets of hairs, looking like "whiskers" to the scull-like crest of the style, on which lots of pollen rest. The small insect on entering the flower can hardly help crawling into the cavity at the top of the stigma, for the entrance to the flower is almost completely blocked up by it. On emerging from it it would crawl over the top, which Mr. Hart mentions as seen in *tricolor*, and which I also find in *cornuta*, be guided through the hole by the triangular mark, and so find his way to the nectary. On emerging, covered with pollen, and entering its next flower, it will again be deluded into the *cul-de-sac* in which the stigmatic surface is, where it will deposit its pollen. The details of the structure of the appendaged stamens, as contrasted with those of other Violas, fully bear out this view.

As regards the English translation for the German *bestäuben*, I would suggest to Mr. Hart that "pollenate" is an impossible word; *pollen, pollinis*, must give the verb to "pollinate," as *fulmen, fulminis* gives *fulminate*. But there is a great advantage in a word which speaks for itself, and, if the word "be-pollen" offends scientific ears (Mr. Hart does not tell us why), would the literal translation of the German "to be-dust" be offensive? If not, I think it would tell its own tale. The word "empollen" seems justified by *embalm*, but the prefix generally means to place in or convert into, as in *enthral, emprison, embed*. Hence it would at least be ambiguous.

The form of Ground Ivy mentioned by your correspondent S.S.D. grows here abundantly in several spots, seeds freely, and is remarkable for having a much shorter style in proportion to the tube of the corolla than the common form in which the style and stigmas protrude from the tube. F. E. KITCHENER

Rugby, June 15

Mr. Kitchener having been kind enough to send me the above letter, I may, perhaps, be allowed to add a few additional notes. Since writing the former paper I have had the opportunity of examining three other species of *Viola*, *V. calcarata, elatior*, and *lactea*, all of which present a remarkable contrast to *V. tricolor* in a very curious point of structure. In *V. tricolor* the stigma is brought into close contact with the lowest petal by a very peculiar "knee" in the style, the effect of which is so completely to close up the central cavity of the flower as to render it extremely difficult for any large insect to insert its proboscis into the spur. In all the three species above-named, which I believe to be fertilised by bees, the style is nearly straight, so as to leave a considerable gap between the stigma and lower petal, quite large enough for the insertion of the proboscis of a bee. In none of these is there the least indication of the black triangular streak on the style which I take to serve, in *V. tricolor*, the purpose of guiding the Thrips to the nectary. The ring of anthers is also perfectly closed, as described by Miss Dowson in the case of the Dog and Sweet Violet, there being no opening for the admission of the small insect, as in the pansy. A striking difference in the form of the stigma also favours the same conclusion as to the mode of fertilisation.

ALFRED W. BENNETT

ON THE ORIGIN AND METAMORPHOSES OF INSECTS*

VI.

THE metamorphoses of insects have always seemed to me one of the greatest difficulties of the Darwinian theory. In most cases, the development of the individual reproduces to a certain extent that of the race; but the motionless, imbecile pupa cannot represent a mature form. No one, so far as I know, has yet attempted to explain, in accordance with Mr. Darwin's views, a life history, such as that of a butterfly, in which the mouth is first mandibulate and then suctorial. A clue to the difficulty may, I think, be found in the distinction between developmental and adaptive changes; to which I have called attention in a previous article. The larvæ of insects are by no means mere stages in the development of the perfect animal. On the contrary, they are subject to the influence of natural selection, and undergo changes which have reference entirely to their own requirements and condition. It is evident, then, that while the embryonic development of an animal in the egg may be an epitome of its specific history, this is by no means the case with species in which the immature forms have a separate and independent existence. If an animal when young pursues one mode of life, and lives on one kind of food, which subsequently, either from its own growth in size and strength, or from any change of season, alters its habits or food, however slightly, it immediately becomes subject to the action of new forces: natural selection affects it in two different and, it may be, very distinct manners, gradually leading to differences which may become so great as to involve an intermediate period of change and quiescence.

There are, however, peculiar difficulties in those cases in which, as among the Lepidoptera, the same species is mandibulate as a larva, and suctorial as an imago. From this point of view *Campodea* and the Collembola (*Podura*, &c.) are peculiarly interesting. There are among insects three principal types of mouth—first, the mandibulate; secondly, the suctorial; and thirdly, that of *Campodea* and the Collembola generally, in which the mandibles and maxillæ are retracted, but, though far from strong, have some freedom of motion, and can be used for biting and chewing soft substances. This type is intermediate between the other two. Assuming that certain representatives of such a type found themselves in circumstances

* Continued from p. 109.

which made a suctorial mouth advantageous, those individuals would be favoured by natural selection in which the mandibles and maxillæ were best calculated to pierce or prick, and their power of lateral motion would tend to fall into abeyance; while, on the other hand, if powerful masticatory jaws were an advantage, the opposite process would take place.

There is yet a third possibility—namely, that during the first portion of life, the power of mastication should be an advantage, and during the second that of suction, or *vice versâ*. A certain kind of food might abound at one season and fail at another, might be suitable for the animal at one age and not at another: now in such cases we should have two forces acting successively on each individual, and tending to modify the organisation of the mouth in different directions. It will not be denied that the ten thousand variations in the mouth-parts of insects have special reference to the mode of life, and are of some advantage to the species in which they occur. Hence no believer in natural selection can doubt the possibility of the three cases above suggested, the last of which seems to explain the possible origin of species which are mandibulate in one period of life and not in another. The change from the one condition to the other would no doubt take place contemporaneously with a change of skin. At such times we know that, even when there is no change to form, the temporary softness of the organs precludes the insect from feeding for a time, as, for instance, is the case with the silkworm. When, however, any considerable change was involved, this period of fasting would be prolonged, and would lead to the existence of a third condition, that of the pupa, intermediate between the other two. Since other changes are more conspicuous than those relating to the mouth, we are apt to associate the existence of a pupa-state with the acquisition of wings: but the case of the Orthoptera (grasshoppers, &c.) is sufficient proof that the development of wings is perfectly compatible with continuous activity; so that in reality the necessity for rest is much more intimately connected with the change in the constitution of the mouth, although in many cases no doubt the result is accompanied by changes in the legs, and in the internal organisation. An originally mandibulate mouth, however, like that of a beetle, could not, I think, be modified into a suctorial organ like that of a bug or a gnat, because the intermediate stages would necessarily be injurious. Neither, on the other hand, for the same reasons, could the mouth of the Hemiptera be modified into a mandibulate type like that of the Coleoptera. But in *Campodea* and the Collembola we have a type of animal closely resembling certain larvæ which occur both in the mandibulate and suctorial series of insects, and possessing a mouth neither distinctly mandibulate, nor distinctly suctorial, but constituted on a peculiar type capable of modification in either direction by gradual change, without loss of utility.

In discussing this subject it is necessary also to take into consideration the nature and origin of wings. Whence are they derived? why are there normally two pairs? and why are they attached to the meso- and metathorax? These questions are not less difficult than interesting. It has been suggested, and I think with justice, that the wings of insects originally served for aquatic and respiratory purposes. From the various modes by which respiration is effected among the different groups of aquatic insects, there are strong reasons for concluding that the original insect stock was, like *Campodea* (Pl 3, Fig. 5), a land animal. But in aquatic insects there is a tendency to effect the purification of the air through the delicate membraneous covering of more or less leaf-like expansions of the skin. In the larva of *Chloëon* (Pl. 4, Fig. 1), for instance, that singularly resembles *Campodea* (Pl. 3, Fig. 5), several of the segments are provided with such foliaceous expansions; which, moreover, are in constant agitation, the muscles of which, in several remarkable points, resemble those of the true wings. It is true that in *Chloëon* the vibration of the so-called branchiæ is scarcely, if at all, utilised for the purpose of locomotion; the branchiæ are, in fact, placed too far back to act efficiently. The situation of these branchiæ differs in different groups; indeed, it seems probable that originally there were a pair on each segment. In such a case, those branchiæ, situated near the centre of the body, neither too much in front nor too far back, would serve the most efficiently as propellers. The same causes which determined the position of the legs would affect the wings also. Thus a division of labour would be effected; the branchiæ on the posterior segments of the thorax would be devoted to locomotion; those on the abdomen to respiration. This would tend to increase the development of the thoracic segments, already somewhat enlarged to receive the muscles of the legs.

That wings may be of use to insects under water is proved by the very interesting case of *Polynema natans*, which I discovered in 1862, and which uses its wings to swim with. This, however, is a rare case; and it is possible that the principal use of the wings was, primordially, to enable the mature forms to pass from pond to pond, thus securing fresh habitats and avoiding in-and-in breeding. If so, the development of wings would tend to be relegated to a late period of life; and by the tendency to the inheritance of characters at corresponding ages, to which Mr. Darwin has called attention,* the development of wings would be associated with the maturity of the insect. Thus the late acquisition of wings in the Insecta generally, seems to be itself an indication of their descent from a stock which was at one period aquatic in its habits, and which probably resembled the present larvæ of *Chloëon* in form, but had thoracic as well as abdominal branchiæ.

If these views are correct, the genus *Campodea* must be regarded as a form of remarkable interest, since it is the living representative of a primæval type from which not only the Collembola and Thysanura, but the other great orders of insects have all derived their origin.

Finally, from the subject of metamorphoses we pass naturally to that most remarkable phenomenon which is known as the "Alternation of Generations:" for the first systematic view of which we are indebted to my eminent friend Prof. Steenstrup.

I have always felt it very difficult to understand why any species should have been created in this double character; nor, so far as I am aware, has any explanation of the fact yet been attempted. Yet insects offer, in the metamorphoses which they go through, a phenomenon not altogether dissimilar, and give a clue to the manner in which alternation of generations may have originated.

The caterpillar owes its difference from the butterfly to the early stage at which it leaves the egg; but its actual form is mainly due to the influence of the conditions in which it lives. If the caterpillar, instead of changing into one butterfly, produced several butterflies, we should have an instance of alternation of generations. Until lately, however, we knew of no such case; each larva produced one imago, and that not by generation but by development. It has long been known, indeed, that there are some species in which certain individuals remain always apterous, while others acquire wings. Many entomologists, however, regard these abnormal individuals as perfect, though wingless insects; and therefore, though these cases appear to me to deserve more attention than they have yet received, I shall not found any argument on them.

Recently, however, Prof. Wagner of Kazan, has discovered that, among certain small gnats, the larvæ do not themselves directly produce the perfect insect, but give rise to other larvæ, which undergo metamorphoses of

* Origin of Species, 4th ed. pp. 14 and 97.

the usual character, and eventually become gnats. His observations have been confirmed, as regards this main fact, by other naturalists; and there can, I think, be no doubt that they are, in the main, correct.

Here, then, we have a distinct case of alternation of generations, as characterised by Steenstrup. Probably other cases will be discovered in which insects undeniably in the larval state will be found to be fertile. Nay, it seems to me possible, if not probable, that some larvæ which do not now breed, in the course of ages may come to do so.

If this idea is correct, it shows how the remarkable phenomenon known as alternation of generations may have originated. At any rate, we find among insects every mode of development; from simple growth on the one hand, to well-marked alternation on the other. In the wingless species of Orthoptera there is little difference, excepting in size, between the young larva and the perfect insect. The growth is as simple and gradual as in any other animal; and the creature goes through nothing which would, in ordinary language, be called a metamorphosis. In the majority of Orthoptera the presence of wings produces a marked difference between the larva and the imago. The habits, however, are nearly the same throughout life, and consequently the action of external circumstances affects the larva in the same manner as the perfect insect.

This is not the case with the Ephemeridæ. The larvæ do not live under the same conditions as the perfect insects; external forces accordingly affect them in a different manner; and we have seen that they pass through some changes which bear no reference to the form of the perfect insect: these changes, however, are for the most part very gradual. The caterpillars of Lepidoptera have even more extensive changes to undergo; the mouth of the larva, for instance, is remarkably unlike that of the perfect insect. A change in this organ, however, could hardly take place while the insect was still growing fast, and consequently feeding voraciously. Nor, even if the change could be thus effected, would the mouth, in its intermediate stages, be in any way fitted for biting and chewing leaves. The same reasoning applies also to the digestive organs. Hence the caterpillar undergoes little, if any, change, except in size, and the metamorphosis is concentrated, so to say, into the last two moults. The changes then become so rapid and extensive, that the intermediate period is necessarily one of quiescence.

Owing to the fact that the organs connected with the reproduction of the species come to maturity at a late period, larvæ are generally incapable of breeding. There are, however, some flies which have viviparous larvæ, and thus offer a typical case of alternation of generations, owing to the early period of leaving the egg, and the action in many cases of external circumstances on the larva different from those which affect the mature form.

Thus, then, we find among insects every gradation, from the case of simple growth to that of alternation of generations; and we see how from the single fact of the early period at which certain animals quit the egg, we can account for their metamorphoses and for the still more remarkable phenomenon that, among many of the lower animals, the species is represented by two very different forms. We may even, from the same considerations, see reason to conclude that this phenomenon may in the course of ages become still more common than it is at present. As long, however, as the external organs arrive at their mature form before the internal generative organs are fully developed, we have cases of metamorphosis; but if the reverse is the case, then alternation of generations often results.

The same considerations throw much light on the remarkable fact, that in alternation of generations the reproduction is, as a general rule, agamic in the one form. This results from the fact that reproduction by distinct sexes requires the perfection both of the external and internal organs; and if the phenomenon arise, as has just been suggested, from the fact that the internal organs arrive at maturity before the external ones, reproduction will result in those species only which have the power of agamic multiplication.

Moreover it is evident that we have in the animal kingdom two kinds of dimorphism.

This term has usually been applied to those cases in which animals or plants present themselves at maturity under two different forms. The different forms of ants and bees afford us familiar instances among animals; and among plants the remarkable case of the genus *Primula* has recently been worked out with his usual ability by Mr. Darwin. Even more recently he has made known to us the still more remarkable phenomenon afforded by the genus *Linum*, in which there are three distinct forms, and which therefore offers an instance of polymorphism.*

The other kind of dimorphism or polymorphism differs from the first in resulting from the differentiating action of external circumstances, not on the mature, but on the young individual. The different forms, therefore, stand towards one another in a relation of succession. In the first case the chain of being divides at the extremity; in the other it is composed of dissimilar links. Many cases of dimorphism under this second form have been described under the name of alternation of generations.

The term, however, has met with much opposition, and is clearly inapplicable to the differences exhibited by insects in different periods of their life. Strictly speaking the phenomena are very frequently not alternate, and, in the opinion of many eminent naturalists, they are not cases of generation at all.†

In order, then, to have some name for these remarkable phenomena, and to distinguish them from those cases in which the *mature* animal or plant is represented by two or more different forms, I think it would be convenient to retain for these latter exclusively the terms dimorphism and polymorphism; and those cases in which animals or plants pass through a succession of different forms might be distinguished by the name of dieidism or polyeidism.

The conclusions, then, which I think we may draw from the preceding and other considerations are:—

1. That the occurrence of metamorphoses arises from the immaturity of the condition in which some animals quit the egg.

2. That the form of the insect larva whenever it departs from the original vermiform type, depends in great measure on the conditions in which it lives. The external forces acting upon it are different from those which affect the mature form; and thus changes are produced in the young which have reference to its immediate wants, rather than to its final form.

3. That metamorphoses may therefore be divided into two kinds, developmental and adaptational.

4. The apparent abruptness of the changes which insects undergo arises in great measure from the hardness of their skin, which admits no gradual alteration of form, and which is itself necessary in order to afford sufficient support to the muscles.

5. The immobility of the pupa or chrysalis depends on the rapidity of the changes going on in it.

6. Although the majority of insects go through three well-marked stages after leaving the egg, still a large number arrive at maturity through a somewhat indefinite number of slight changes.

* Of course all animals in which the sexes are distinct are in one sense dimorphic.

† "There is no such thing as a true case of 'alternation of generations in the animal kingdom; there is only an alternation of true generation with the totally distinct process of gemmation or fission."—*Huxley on Animal Individuality*, Ann. and Mag. of Nat. Hist., June 1852.

7. When the external organs arrive at this final form before the organs of reproduction are matured, these changes are known as metamorphoses; when, on the contrary, the organs of reproduction are functionally perfect before the external organs, or when the creature has the power of budding, then the phenomenon is known as alternation of generations.

8. Thus, then, it appears probable that these remarkable phenomena may have arisen from the simple circumstance that certain animals leave the egg at a very early stage of development, and that the external forces acting on the young are different from those which affect the mature animal.

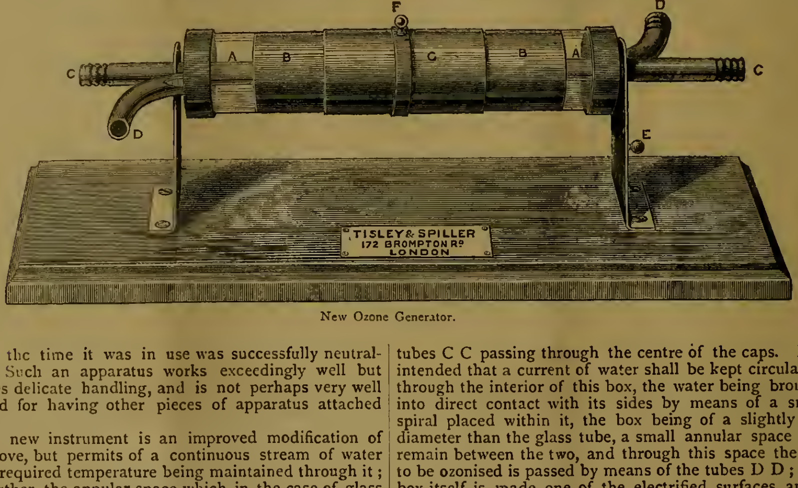
ON AN IMPROVED FORM OF OZONE GENERATOR

A SHORT description of an improved form of ozone generator, exhibited at the last meeting of the Chemical Society, may perhaps be interesting to the readers of NATURE.

Probably no apparatus hitherto introduced, for the production of ozone by electric induction, has in its working given universal satisfaction. The original form of "Siemens' tube" has many disadvantages, amongst which the chief are, the extremely fragile nature of the two glass tubes, especially when sealed together by the blowpipe, and the fact that if the apparatus be worked for any length of time it becomes heated, thereby causing a diminution in the quantity of ozone obtained. The arrangement of a number of glass plates coated on alternate sides with tin foil, and enclosed in a box, known as "Beane's" instrument, possesses—especially if used as it is intended it should be with a large and powerful coil—this latter disadvantage to a considerable extent. Sir Benjamin Brodie, during his researches upon ozone, used a modification of "Siemens' tube," which in a great degree overcame this difficulty. Two glass tubes closed at one end, and of such diameter that one was capable of sliding within the other, were fixed together in that way, the junction being effected either by the blowpipe or by means of paraffin, thus leaving a small annular space between them through which the oxygen or other gas to be ozonised could circulate; tin foil coatings were dispensed with altogether, the inner tube being filled with water, and the whole apparatus stood in a vessel of water, wires in conection with an induction coil being placed in the interior tube, and also in the outer vessel: this water could be kept cool by ice, and thus any heat produced



New Ozone Generator.

during the time it was in use was successfully neutralised. Such an apparatus works exceedingly well but requires delicate handling, and is not perhaps very well adapted for having other pieces of apparatus attached to it.

This new instrument is an improved modification of the above, but permits of a continuous stream of water of any required temperature being maintained through it; and further, the annular space which in the case of glass tubes is often very irregular, causing thereby an unequal electrical discharge. is made as true as possible, and the result is a more uniform conversion of the gas into ozone. The apparatus as at present made will be better understood by the following description referring to the accompanying diagram:—A A is a piece of glass tube of a little more than one inch in diameter, and of as uniform a bore as can be obtained. On each end of this tube is placed a brass cap, bored with two holes, and coated internally with shellac; in the interior of this glass tube and of a diameter scarcely less than that of the tube itself, but not quite so long, is placed a thin hollow brass box, B B, with its surface made as true as possible by turning in a lathe; this brass box is placed concentrically with the outer tube and is completely coated on its exterior surface with tin, the tin being acted upon to the smallest extent by the ozone. This hollow box communicates with the exterior of the apparatus by means of the tubes C C passing through the centre of the caps. It is intended that a current of water shall be kept circulating through the interior of this box, the water being brought into direct contact with its sides by means of a small spiral placed within it, the box being of a slightly less diameter than the glass tube, a small annular space will remain between the two, and through this space the gas to be ozonised is passed by means of the tubes D D; the box itself is made one of the electrified surfaces, and a strip of tin foil G, fixed to the outside of the glass tube, forms the other; two binding screws, E and F, serve to make the necessary connections with an induction coil.

The production of ozone by this apparatus is exceedingly regular and constant. No quantitative estimations with iodide of potassium and sulphurous acid have as yet been made with regard to the amount of ozone obtained, but an approximate experiment upon the quantity of indigo bleached in a given time, seems to indicate that this amount is quite equal to, if not rather in excess of, that obtained when the ordinary apparatus is used. This instrument possesses also some minor advantages; it is not so easily broken, other pieces of apparatus are very readily attached to it, and at the same time its cost is less. There appears to be no reason why larger forms should not be manufactured upon the same principle. These instruments are made by Messrs. Tisley and Spiller of Brompton.

THE LAW OF STORMS DEVELOPED*

II.

IT has been asserted lately that the Gulf Stream has no influence upon storms; that they have no tendency to run toward it or to run upon it; and that what geographers and seamen have always said about the Gulf Stream as a "weather-breeder" and "storm-king" is absurd. I think it can be demonstrated that this well-known popular belief is not absurd.

It is an observation as old as Aristotle, that the storms of the middle latitudes in the Northern Hemisphere advance from west to east. This is obviously partly due to the fact that the winds on their eastern sides are southerly, that they come from the equatorial regions, and hence are highly charged with aqueous vapour. This vapour is absolutely essential to the sustenance of the storm. Moreover, the law of storms requires that the southerly winds should enter the storm-vortex on the eastern side, and as this is the side on which the greatest quantity of vapour is found, and the side of greatest condensation, of the greatest evolution of latent heat, hence of the greatest aërial rarefaction and barometric fall, to this side the heavier air from the west will push as into a great hollow. Thus do we actually find that all storms, formed west of the Gulf Stream, are actually propagated toward it. It may be argued from the above facts that the anti-trade winds are thus maintained by storms incessantly making the circuit of the globe within the temperate zone. But in reality, instead of being the effect of storm influence, the anti-trades are originated by independent solar agency, as are the trades, and they are potential and causal in producing the eastward progression of all cyclones. It must be conceded that the pressure of vast aërial currents does serve to force the meteor along with them as the river-eddy is carried down stream with the water-current; otherwise it is impossible to explain the westward progression of tropical hurricanes. While yet in the band of easterly trade-winds the storm will invariably work its way or be propagated toward *the most humid region*, unless mechanically borne in another direction by the great atmospheric current in which it is often embedded as an eddy in a river. The cyclone-tracks over all the oceans lie in the central bands of the great ocean-currents of high temperature and great evaporation, and the band of cyclonic violence is often beautifully coterminous with the sharply-marked blue-tinted edge of the Gulf Stream. Thus, in the Pacific, the Loochoo Islands lie just in the path of the Kuro Siwo, the great Pacific Gulf Stream of the Japanese, and are visited by the most fearful typhoons; but the Bonin Islands, in the same parallel, but on the extreme margin of the Kuro Siwo, have very mild and moderate storms.* "If a storm commences anywhere in the vicinity of the Gulf Stream, it naturally tends towards that stream, because," as Loomis says, "here is the greatest amount of vapour to be precipitated, and when a storm has once encountered the Gulf Stream, it continues to follow that stream in its progress eastward." Vessels and Japanese junks, dismasted in gales off the Asiatic coast, have been drifted for many days in the current of the Kuro Siwo, to the coast of California, just as West-Indian beans, cocoa-nuts, and vegetables, have been drifted to Iceland, Greenland, and Spitzbergen, on the extension of the Gulf Stream. According to all meteorological observations of the tracks of storms, we are warranted in believing that cyclones and hurricanes do, as a matter of fact and of atmospheric law, run on the hot currents of the sea as naturally as the watercourse clings to its bed. Practical seamen, though unable to

FIG. 3.—The Atmospheric Movements.

* Continued from p. 124.

* See Redfield's Report on Pacific Cyclones.

explain the fact, are always on the look-out for these furious gales when sailing on the axial lines of the Gulf Stream, on the hot Mozambique current (the Gulf Stream of the Indian Ocean), and on the dark superheated waters of the Kuro Siwo of the Pacific.

So dangerous and disastrous are the storms which course along the Gulf Stream that sailors avoid it, and the American Sailing Directions and those of the British Admiralty advise all vessels, sailing from the West Indies to New York or Liverpool, to beware of taking advantage of its current, although it would help them along from three to four miles an hour. Close observation has traced these storms continuously from the Florida coast to New York, through Redfield's labours, and thence to England, through the records of the Cunard steamships, and thousands of detached observations.

We have now reached a point where we can properly and intelligently consider a question that has always baffled meteorologists—the origin of cyclones. The diagnosis of the phenomenon necessarily precedes its explanation. This subject has engrossed many minds, and various have been the ingenious devices for unravelling its mystery. Mr. Redfield—the father of storm physics—in his modesty and diffidence, so distrusted himself and in his day so keenly felt the need of a more enlarged induction of facts, that he has scarcely left us his opinion. The theories of other writers have all long since been abandoned by themselves or suffered to drop from the notice of the scientific world as evidently incapable of explaining the phenomena of cyclones. This has been the fate of them all, unless possibly we except the theory advanced by the great meteorologist, M. Dové, of Berlin. Briefly stated, the latter hypothesis is this (at least in its application to West Indian hurricanes), viz., that "they owe their origin to the intrusion of the upper counter trade-wind into the lower trade-wind current" (Dové's "Law of Storms," p. 264).

Without pausing here to examine this theory upon its merits and upon the facts, we hasten to mention a different hypothesis advanced, nearly two years ago, as a substitute for that of M. Dové, and as affording an entirely original and satisfactory explanation of the origin of cyclones.

The hypothesis was likewise based upon the agency of the trade-winds, but in a manner wholly different from that elaborated by the German meteorologist. In the original paper in which my views were published, the following statement was made :—"It can be demonstrated that the origin of cyclones is found in the tendency of the south-east trade-winds to invade the territory of the north-east trades, by sweeping over the equator into our hemisphere."

The hypothesis advanced, in lieu of another seemingly less satisfactory, claimed to rest upon observations conducted in the very region most notorious for the generation of cyclones.

To test this, we need only to examine the Atlantic trade winds.

Theoretically, physical geography has generally represented the motions of the atmosphere somewhat as is represented in the accompanying diagram (Fig. 3) of the winds, as projected by Prof. William Ferrel, of Cambridge. The elaborate pages of Prof. Coffin, in his invaluable volume on the "Winds of the Northern Hemisphere," as deduced from myriads of observations, show that the graphic illustration furnished by the diagram is approximately correct.

The region of the trade winds, it will be seen, more than covers the torrid zone of the earth, and at all the seasons of the year overlaps both the northern and southern tropics. While this is theoretically true, and is usually put forth as a fact, it must be accompanied with one or two important qualifications and additions.

Let us see what these are. The well-known oscillation or swinging of the belts of winds to and fro on the meridians, which is kept up in never-ceasing response to the apparent annual motion of the sun as he crosses and recrosses the equator, must ever underlie the conception we form of the trade winds and be perpetually present to the mind's eye. This oscillation has never yet received the popular attention it needs. The sun traverses (apparently) an arc of $23\frac{1}{2}°$ on either side of the line ; and we might, *a priori*, suppose that the thermal or meteorological equator, the thermal or meteorological Tropics of Cancer and Capricorn, and all those phenomena which lie between them and beyond them, move over an arc of as many degrees as they traverse. Such an inference, however, is not borne out by observation, and we propose to confine ourselves strictly to what may be proved by observation. It is clear that the trade-wind belt does traverse or vibrate over a wider zone than any physicist has yet assigned to it, which is not more than ten degrees of latitude north and south respectively of the Tropic of Cancer and that of Capricorn. These winds, when first experienced by Spanish sailors, gave, to that portion of the Atlantic over which they blew, the name *el Golfo de las Damas* (the Ladies' Sea) because they rendered navigation so easy that a girl might take the helm. But, "gentle" as they are, they have a wide sweep, and, in the summer of the Northern Hemisphere, extend far beyond the Tropic of Cancer. They have often been distinctly felt at Madeira and the Azores (near the 40th parallel) in summer, and it is highly reasonable to suppose that they then fully reach the latitude of 40° N. The equatorial side of the north-east trade-wind belt, of course, vibrates with the sun. In summer it stretches along between the 10th and 12th parallels of north latitude, verging in August on the 13th parallel, and, according to one writer, occasionally the north-east trades at that season do not extend south of the 15th parallel of north latitude. Dampier, "the prince of navigation," as the English call him, gives the direction of the wind in the summer months, between the equator and 12° north, as south-south-east, south-south-west, and south-west.

The equatorial side of the north-east trade-wind belt in winter approaches very nearly to the equator, and may be located in January at least as far south as the latitude of 2° north.

The freshest trade-winds in the North Atlantic are generally found between the parallels of 10° and 25°, and by long protracted experiment in seamanship they have been found to have an average propelling power, when the wind is taken just abaft the beam, of about six knots an hour. But, of course, the northern boundary of the south-east trade-wind likewise varies and vibrates with the seasons. So also, and under the same condition, does the southern boundary of this trade vary and vibrate with the seasons. Its normal and mean position is a little south of the parallel of 25° south, but in the winter of our hemisphere it is pushed much farther south, and in the vicinity of 35° south latitude. The charts of Captain Wilkes give easterly winds for the east coast of Australia, and also for the south coast of Africa. Sir John Herschel, speaking from knowledge gained by his long residence at the Cape of Good Hope, tells us that there "the south-easterly winds which sweep over the Southern Ocean, infringing upon the long range of rocks which terminates in the Table Mountain, is thrown up by them, makes a clean sweep over the flat table-land which forms the summit of that mountain (about 3,850 ft. high), and thence plunges down with the violence of a cataract" ("Meteorology," p. 96).

From these high southern latitudes, we must conceive the motion of the south-east trades, extending northward in summer to the neighbourhood of the parallel of 10°.

(*To be continued.*)

THE CORONAL ATMOSPHERE OF THE SUN*

II.

WHEN the subject is a phenomenon so complex as that of the corona, it is necessary to bring to bear upon it various methods of study. This is why I have thought it indispensable to consider the corona from the triple standpoint of its aspect, the analysis of its light, and its polariscopic manifestations. Let us discuss these varied observations.

Let us first of all see what can be learned from an examination of the corona during the first instants of totality. We have seen that the general structure of the corona persisted throughout the duration of totality. We cannot, then, admit here any effect of diffraction engendered at the surface of the lunar screen by the rays grazing the edges of that screen Let us revert to the geometric circumstances of a total eclipse. At the moment when totality is produced, the disc of the moon is tangent, at one point, to that of the sun, and edges off gradually more and more to the opposite point. Diffraction will be produced, then, under physical conditions the most different, at various points of the lunar limb, and an aureole due to that cause will reveal, by its dissymmetry, such a diversity of conditions. Moreover, an aureole of this kind will present a continually varying aspect during the various phases of totality. Unsymmetrical at the outset, it will be modified with the movement of the moon, and will tend to assume the same form all round our satellite, when the disc of the latter is equidistant from that of the sun. Finally, from that point this aureole will pass through the same phases inversely until the reappearance of the sun.

However, nothing like this was produced at Shoolor. The general structure of the corona remained the same throughout the continuance of totality.†

It is unnecessary to dwell on the hypothesis of an aureole produced by a lunar atmosphere. We know now that if a gaseous layer exists on the surface of our satellite, it must be of so small extent that the grand phenomenon of a corona could not be produced by it.

Our own atmosphere cannot be adduced as the cause of the phenomenon, though it is evident that it plays an important part in the particular aspects which the corona may present at different stations, according to the state of the sky at these stations. It acts as a modifying, but not as a producing cause.

Let us pass, meanwhile, to the spectroscopic observations. The corona presents the hydrogen lines throughout all its visible extent; in certain parts as far as to 12′ or 15′ in height. This observation is certain. The precision of the spectroscopic scales, the experience we have had in such determinations, and the care which was taken in the last observation to compare the lines of the corona with those of a protuberance, of which they are only a prolongation, leaves no doubt as to this point.

But if the corona presents the hydrogen lines, we must ask this testing question—Is this light emitted or reflected? The constitution of the coronal spectrum will afford us an answer.

If the light of the corona is reflected, this light can only have a solar origin. It proceeds from the photosphere and the chromosphere, and its spectrum ought to be that of the sun, that is, a luminous ground with obscure lines. But such is not the constitution of the coronal spectrum; that presents to us the hydrogen lines standing in strong relief on the ground; after the green line (1474) this is the most striking manifestation in the phenomenon. We must conclude that the coronal medium is self-lighted, in great part at least, and that it contains incandescent hydrogen. This first point is conclusively established. But is it to be inferred from this that the whole of the light of the corona is emitted light? Evidently not; and on this point a delicate observation in spectrum analysis and polarisation may inform us. In fact, the spectrum of the corona presented to me, besides these bright lines, many obscure lines of the solar spectrum, the line D, and some in the green. This fact proves the presence of reflected solar light. We may ask why the principal Fraünhofer lines are reduced to the line D. It should be remarked that the coronal spectrum, not being very luminous, is especially perceptible in its central part, and that, in this part, the lines C, F, &c., are replaced by the bright lines. In these conditions the line D alone remains important; thus it is on it I have directed all my attention. As to the finer lines, they were much more difficult to discern, a fact very easily explained by the very large opening I was obliged to give to the slit of the spectroscope.

The proof of the existence of the Fraünhofer lines in the spectrum of the corona is a work of delicacy; it was not obtained by the other observers. This fact is explained partly by the great purity of the sky at Shoolor, partly by the power of my instrument. I have no doubt that the observation will be confirmed by astronomers who work under conditions equally favourable.

The presence of reflected solar light in the spectrum of the corona is of great importance; it shows the double origin of this coronal light; it explains observations of polarisation which appeared irreconcilable;* but above all, it enables us to understand how the solar light forming in some sort the ground of the spectrum of the corona, this spectrum may be considered continuous; and we know that hitherto this circumstance has been the great obstacle which prevented the corona from being regarded as entirely gaseous. The phenomena of polarisation presented by the corona are for the most part those of radial polarisation, which shows that reflection takes place chiefly in the corona, and that that which may be produced in our atmosphere is only secondary. Polarisation then agrees here with my observation of the Fraünhofer lines; but in order that the agreement may be complete, it is necessary that the polariscopic analysis, like the spectral analysis, should show that the light of the corona is only partially reflected. This is precisely what happened. We have seen, in fact, that near the limb of the moon, where the coronal light is brightest, polarisation appears less pronounced than at a certain distance. The reason is, that in the inferior regions emission is so strong that it conceals reflection, and the latter appears, with its peculiar characteristics, only in the layers where it is able to assume a certain relative importance.

Thus the two analyses, spectral and polariscopic, fairly interpreted, agree as to the double origin of the coronal light, and all the observations unite in demonstrating the existence of this circumsolar medium. This medium is distinguished both by its temperature and by its density from the chromosphere, of which the limit, moreover, is perfectly distinct, as is shown in all the drawings of the protuberances and of the chromosphere. There is thus a necessity for giving it a name: I propose that of "coronal envelope" or "coronal atmosphere," to remind us that the luminous phenomena of the corona owe to it their origin.

The density of the coronal atmosphere must be excessively rare. In fact, it is known that the spectrum of the chromosphere in its superior parts is that of a hydrogen medium successively rarified; but as the coronal medium, according to the indications of the spectrum, ought to be even infinitely less dense, we see how rare this medium

* Continued from p. 127.

† It is quite evident that this constancy of aspect only agrees with points of general structure sufficiently distant from the sun not to be influenced by variations of light resulting from the displacement of the moon, relatively to the low and very luminous regions of the chromosphere.

* If we consult the history of eclipses we shall see that observers have often obtained contrary results, which has been the means of casting a kind of discredit on this kind of observation. But if these observations are considered in view of the double nature of the light of the corona, and of the effects of our atmosphere, we shall be able to remove most of the difficulties.

must be. This conclusion is further corroborated by astronomical observations. Science has recorded the passage of comets as only some minutes' distance from the surface of the sun; these bodies must have traversed the coronal atmosphere, and yet, notwithstanding the lightness of their mass, they did not fall into the sun.

I shall add here, as to the constitution of the coronal atmosphere, a few ideas which do not rigorously flow from my observations, but which appear to me very probable, but upon which the future must pronounce.

I said, *à propos* of the observations in the telescope, that the corona was shown at Shoolor with a form almost square, and that it was distinguished by gigantic dahlia-like petals. It is a fact that in each eclipse the figure of the corona has often varied; it has exhibited the most eccentric appearances. I have no hesitation in saying that this medium, now incontestably recognised, and which I propose to name the "coronal atmosphere," very probably does not represent the whole of the aureole which is seen during total eclipses. It is quite credible that portions of the rings or trains of the cosmical matter then become visible and thus tend to complicate the figure of the corona. It belongs to future eclipses to instruct us on this point. But with regard to the coronal medium itself, there is no doubt that it presents singular forms, which convey but little idea of an atmosphere in equilibrium. Moreover, I am inclined to admit that these appearances are produced by trains of very luminous and dense matter from the superior layers ploughing this troubled medium. The protuberant jets, which carry the hydrogen to such great heights, must have a peculiar influence upon this coronal medium, whose density is quite comparable to that of the cometary media.

It is, then, very probable that the coronal atmosphere, like the chromosphere, is very much agitated, and that it changes its shape very rapidly, which will explain how it presents different appearances every time it has been observed.

To repeat: I have been able to establish at Shoolor, by trustworthy and consistent observations, that the solar corona presents the optical characteristics of incandescent hydrogen gas, that this very rare medium extends to very variable distances from the sun, from half a radius of the sun to about double that at certain points; but I give these figures only as results of an observation, not as definitive. It is quite certain, moreover, that the height of the corona must be necessarily variable.

This result seems to be a considerable advance in the general problem of the corona. If our foreign rivals have not obtained a result so decisive* as those of the French mission, I believe it must be attributed to the altogether exceptional purity of the sky in the station which I chose with such pains, and also to the combined optical arrangements which gave to the luminous phenomena which it was the object to catch, an exceptional power.†

JANSSEN

* M. Respighi, at Poodookotah, made observations purely spectroscopic which confirm mine; only he found the height of the corona much less, which appears to me to be due to the more feeble luminous power of his instrument.

† This paper contains only an analysis of my observations: I have not been able to refer in detail to those of other observers. I may cite, however, the important remarks of Mr. Lockyer on the structure of the corona, the photographs of Colonel Tennant, the polariscopic observations made at Jaffna, those of Capt. Fyers, M. Oudemans, and others.

CHRONOMETER TESTS

THE following, which has been sent us by the Scientific Editor of *Harper's Weekly*, shows with what minuteness the scientific work of this country is studied in America, and what a critical audience we have on the other side of the water:—One of the most important services that astronomy has rendered to mankind consists in the contributions it has made to the progress of navigation, and the increased security of life and property. In this field England has always taken the lead, and the efforts of Mr. Hartnup at Liverpool are a worthy continuation of the labours of Flamstead, Bradley, and Airy. While the Greenwich Observatory has caused a great improvement in the general standard of the chronometers bought for the use of the Government vessels, Mr. Hartnup has sought to effect a similar reform for the mercantile marine. He has insisted on the vital importance to ship-masters, as well as to owners and insurance companies, of the careful determination of the rates of their chronometers as affected by temperature. The makers of these instruments and the astronomers who use them carefully have always known that which captains of vessels have been very slow to profit by—*i.e.* that the chronometers are, when made, so adjusted that they keep perfect time at two temperatures, such as 55° and 85° F., while between these limits they gain, and beyond them they lose, on the true time. It is rare that this variation in the chronometer rate can be safely overlooked by a careful navigator, though it is frequently done by those whose vessels do not carry a precious burden of 1,000 or 2,000 souls. The only excuse for this neglect is the positive assurance of the maker that the chronometer is perfectly reliable—an assurance that is often fortified by very deceitful figures. The difficulty and expense of a searching investigation into the errors to which every chronometer is liable have long been supposed by the trade to stand in the way of the introduction of such chronometers only as were of approved reliability. In order to obviate the difficulty as far as possible, the Liverpool Observatory has been constructed by Mr. Hartnup specially for the purpose of studying the rates of the chronometers that may be sent thither by captains sailing from that port. The expense of the examination given to such chronometers is comparatively trifling; and the number of chronometers submitted to him has annually increased, until by reason of the recent regulations at that port the number of examinations has amounted to between 1,000 and 2,000 annually, the same instruments having been repeatedly submitted to him. The process pursued by Mr. Hartnup consists in exposing each chronometer for a week to a uniform temperature of 55°, and determining its rate each day; it is then for another week exposed to a temperature of 70°, and then to one of 85°; the next week it is returned to the temperature of 70°, and the last or fifth week it is exposed to the temperature of 55°, as at first. By means of general laws regulating the rates of chronometers it is now possible to determine what the rate will be at other temperatures than the three above mentioned, and knowing these, the navigator is able to apply the proper correction to his time-keeper so exactly that he need never mistake his position upon the ocean.

The records of the Liverpool Observatory for the past year show—1. That the rates of about 10 per cent. of the chronometers tested (those of the mercantile marine very generally have the ordinary compensation balance) are so irregular as to render the instruments entirely unfit for nautical purposes. 2. The error of adjustment for temperature of the remaining 90 per cent. is often so erroneous as to produce a change of daily rate of many seconds, when the temperature varies but little from either of the two standard points of 55° and 85°, or thereabouts. 3. That the best made and most carefully adjusted instruments gain, on the average, daily six-tenths of a second more at a temperature of 70° than at 55° or 85°. 4. That those that have the same rate at 55° and 70°, or at 70° and 85°, lose when exposed to temperatures beyond these limits at the rate of 1·5 seconds daily for a change of 15° in temperature. 5. That when the connection between temperature and daily rate has been well determined, it will remain constant in good instruments for a

long time, which need in general to be examined only once in one, two, or three years.

The vital importance of this subject to the interests of safe, speedy navigation, will be impressed upon everyone by the disaster that befell the *Atlantic*, consequent upon being some twenty miles (or ninety seconds of time) out in her reckoning.

NOTES

LAST Thursday the gentlemen already named by us were elected Fellows of the Royal Society.

THE Baly Medal for physiological research has been awarded to Dr. Sharpey.

A PORTION of the collection made by the naturalist D'Albertis in New Guinea, and referred to in our Notes last week, has already arrived in England, and at the meeting of the Zoological Society, on Tuesday, June 17, Mr. Sclater, F.R.S., announced that among other valuable species, it contained both male and female specimens of a previously unknown Bird of Paradise of the Epimachine division, with a peculiarly long and curved beak, which he proposed to name *Drepanephorus albertisi*, after its discoverer.

A PROJECT has been set on foot by Colonel Grant, so well known from his African travels, to form a loan exhibition of skulls and horns of hollow-horned animals, in order that by observation and comparison of a large number of characteristic specimens, facts may be obtained regarding the form, sexual characters, and locality of each particular species. It is proposed to have as many as from twenty to fifty specimens of each species, so as to be able to form groups representing every stage in the life of each, as also to show the varieties of species in different localities. When from three to five thousand specimens of the one hundred and fifty existing species has been promised, means will be taken to secure the most suitable place in London for their exhibition.

ARRANGEMENTS have been made, under the sanction of Dr. Whewell's friends and executors, for the publication of a life of the late Master of Trinity, with selections from his correspondence and remains. The literary and scientific remains and correspondence will be edited by Mr. Todhunter, Lecturer, and ormerly Fellow of St. John's College, Cambridge. The account of Dr. Whewell's college and university career will be written by Mr. W. G. Clark, Senior Fellow of Trinity College, Cambridge. Some of the most distinguished of Dr. Whewell's friends, to whom application has been privately made, have kindly placed their papers at the disposal of the editors, and expressed their approbation of the proposed work. The editors now ask in a more public manner for the loan of letters or other materials which will assist them in their labours. Mr. J. L. Hammond, Fellow of Trinity, as the surviving executor under Dr. Whewell's will, has undertaken to receive, on behalf of the editors, any documents that may be intrusted to them, all of which will be catalogued and carefully preserved, and returned within such limits of time as may be prescribed.

A CONFERENCE took place on Saturday, in promotion of a project to which we have already alluded as the "Trades Guild of Learning," for extending the advantages of university education to the working and middle classes of this country. It is proposed that local organisations shall be formed in various towns, and put into communication with a central guild, for the purpose of defraying the cost of the attendance of duly authorised lecturers sent from the Universities of Oxford and Cambridge, to conduct classes and deliver lectures on subjects, such, for example, as Political Economy, English Literature, Force and Motion, Astronomy, Physical Geography, &c. Technical education is to form a leading department of the scheme, and it appears that Nottingham, Derby, and Leicester have already made arrangements and fixed dates for receiving the lectures, and that the authorities of both Universities, but that of Cambridge especially, have given cordial encouragement to the idea. Saturday's conference was very fairly attended by representative working men in the capacity of delegates from societies more or less numerous and powerful, and the whole day from eleven in the morning until seven in the evening was occupied in the discussion of the project. Mr. Samuel Morley, M.P., presided for the first few hours, and was succeeded in the chair by Mr. Mundella, M.P. With them were the Rev. H. Solly, Mr. James Stuart, M.A., Hon. Sec. to the Syndicate, who is actively engaged in furthering the scheme in connection with the Universities, Mr. Webster, Q.C., and other gentlemen, and a few ladies. It was agreed that women should not be excluded from the advantages of the guild.

ON June 7 a meeting was held of the Druitt Testimonial Committee, at which it was reported that a handsome silver cup, along with 1215*l*., was to be presented to Dr. Druitt, who is still in India.

THE subscribers to the Children's Hospital, Bristol, have resolved to admit female practitioners to the medical staff of the hospital.

THE following, in alphabetical order, have passed first-class in Natural Science at St. John's College, Cambridge:—Clough, Jukes-Browne, Koch, Marshall, Sollas. Of the above, Marshall has been elected to a Foundation Scholarship, Clough, Jukes-Browne, Koch, Sollas (scholar 1872) have been awarded exhibitions.

IN the last issued Part of the *Birds of Europe*, which has just appeared, the name of Mr. Sharpe is no longer associated with that of Mr. Dresser as co-editor. The former of these two gentlemen has been compelled, on account of his many duties at the British Museum, to retire from his connection with the work which he was so instrumental in organising, and Mr. Dresser is now sole editor. The Viscount Walden, F.R.S, President of the Zoological Society, has relieved him of part of his considerable task, by undertaking to write most of the synonyms of the future parts, which will be sufficient guarantee for its accuracy and exhaustiveness.

THE concluding Part of Dr. W. L. Buller's *Birds of New Zealand* has just been issued. The genus *Apteryx*, the last discussed, and most interesting in the avifauna of these islands, is divided into four species at least, of which *A. haasti* closely resembles *A. owenii*, except in size, being considerably larger. The author also considers that the evidence, as far as it goes, is in favour of *A. haasti* differing from *A. maxima* of M. Jules Verreaux, which he thinks represents another species as large as a full-grown turkey. The Introduction contains several interesting supplementary notes; further facts are given in favour of the Quail Hawk (*Hieracidea novæ-Zealandiæ*) being distinct from the Sparrow Hawk (*H. brunnea*); the validity of *Platycercus alpinus*, as a species, is established; the Huia bird (*Heteralocha acutirostris*) is placed among the Starlings, close to *Creadion* instead of with the *Upupidæ*, and *Tribonyx mortieri* is included in the New Zealand fauna. There are seven excellent plates, and a supplementary series is promised.

THE recent changes which took place in French policy have deprived science of an active and able leader in M. Jules Simon, who was sparing no trouble to promote new inquiries and restore French science to its pristine activity. His imme-

diate successor has had no time to make any show of his intentions. M. Batbie seems to feel inclined to accept the inheritance of M. Jules Simon, as far as it relates to the *Facultés* (the equivalent of the several English Universities). It is supposed on good grounds that all the schemes of M. Jules Simon for building a new Faculté of Sciences on the back part of the Luxembourg will not be interfered with by the sudden presidential change. It remains to be ascertained what will be the working of the new system on the courses of lectures delivered by unofficial men of science.

M. LEVERRIER has entered on his new office of Director of the French National Observatory. The Observatory Board has decided on his formal proposition that they shall co-operate with the Bureau des Longitudes for taking a new measure of the French arc from Dunkerque to Oran *vià* Spain. Commander Perrier will be the chief geodesist for that most important survey.

M. WOLF has taken a series ot magnificent photographs with Leon Foucault's siderostat during the last partial eclipse. He was then testing the photographic process which he intends using in Japan on the next Transit of Venus. The Japan Embassy was present at the operations and exhibited a great deal of truly scientific curiosity.

M. THIERS is now busy studying geology for the purpose of writing an essay on the destiny of mankind. He will take an anti-Darwinian view of the question. M. Daubree is his teacher for geology. He was taught in astronomy ten years ago by M. Leverrier, and in Natural Philosophy by M. Mascart, lecurer at the Collége de France.

M. BARTHELEMY SAINT-HILAIRE has already resumed his wo k of translating Aristotle and commenting upon it. The volumes now in hand relate to scientific subjects.

MESSRS. MACMILLAN & Co. will shortly publish the "Elements of Embryology," by Michael Foster, F.R.S., Prelector in Physiology at Trinity Coll. Cambridge, and F. M. Balfour, Scholar of Trinity College, Cambridge.

THE French Academy has named a commission to prepare a list of candidates for the place of Foreign Associate, vacant by the death of Baron Liebig. The commission is composed of MM. de Quatrefages, Liouville, Morin, Becquerel, Dumas, Chevreul, and Milne-Edwards.

TURIN possesses an Industrial Museum, which, though it has been established only a few years, is, according to *L'Institut*, one of the most complete in Europe, second only to the Conservatoire des Arts et Métiers de Paris. The value of this establishment has just been increased by the publication of a monthly periodical entitled *Annals of the Italian Industrial Museum*. The Director of the Museum is M. Codazra, and the Cons rvator, Mr. W. T. Jervis.

M. PAUL BROCA contributes to the *Revue Scientifique* an account of some researches he made about twelve years ago for the purpose of ascertaining the influence of education on the development of the brain. He took as his subject 20 attendants and 18 pupils of the hospital of Bicêtre, the average age of the former being 39½ years, and the average height 1·643 metre; the average age of the latter 26½ years, and the average height 1·689 metre. Notwithstanding the great advantage of the former in the matter of age—for it has been ascertained that the mean weight of the brain increases up to 40 years—the measurements made by M. Broca were very considerably in favour of the pupils, who had undergone a long training before being admitted to the hospital, and some of whom have since had a distinguished career. We can only here give the differences between the various measurements of the two groups of heads, the + denoting the excess (in millimetres) in favour of the hospital pupils. Antero-posterior diameter—Maximum + 4·89, inial + 5·87; transverse diameter + 2·91; cephalic cephalometric index − ·55; inio-frontal curve—total + 9·90, anterior part + 9·25, posterior part + 0·65: horizontal curve—total + 16·06, anterior part + 10·90, posterior part + 5·16; transverse curve—bi-auricular + 13·90, supra-auricular 11·70. M. Broca thinks that the results of the measurements prove, in the first place, that mental culture and intellectual work increase the volume of the brain, and in the second place that the increase takes place principally in the frontal lobes, which are the seat of the highest faculties of intelligence. Very important conclusions in favour of the spread of the higher education may be drawn from these statistics.

WE are glad to see, from a pamphlet by Mr. Ellery (just elected F.R.S.), "Notes on the Climate of Victoria," that a beginning has been made to put into shape the multitude of statistics which have already been accumulated as to the climate of that country. With regard to the rainfall, we quote the following paragraph:—By selecting Melbourne as the locality in which the most extended series of observations have been obtained, we remark that in the years 1848, 1849, and in 1863, the rainfall was far above the average; in 1864, 1865, 1866, and 1870 it fell below the average, especially 1865, when it only reached 15·9 inches. In 1848 and 1849 extensive and destructive floods occurred, and again in 1863; in 1865 and 1866 the country suffered from a severe drought; and the year 1851, following the heavy rains of 1849, was also a dry one, although the amount of rainfall, if ever observed, cannot yet be ascertained. An opinion has often been expressed that there is a periodicity in the excessive rainfalls and droughts in Australia generally; but although the above results may give some slight grounds for this supposition, a far greater number of years' observations will be necessary from which to deduce any law of this kind.

THE United States Signal Corps has recently extended its series of observations in the form of a daily record of the surface and bottom temperature of the rivers and harbours upon which the several stations are situated. This, while of much interest in a meteorological point of view, is also of practical importance in connection with the subject of introducing useful food fishes into the rivers and lakes of the United States, as lately provided for by Congressional enactment. It is well known that the possibility of introducing salmon into any given stream will depend upon the relationship of its temperature during the summer and autumn to the particular species; some kinds, as the true salmon of the North Atlantic (*Salmo salar*), requiring a summer minimum of at least sixty to sixty-five degrees, while others will bear a higher temperature.

AN institution has been founded in Vienna by M. Anton M. Pallac, which he calls a Rudolfinum, or Students' Home—a college of technical science for students of any nationality. It is now announced that this gentleman has arranged with the officers of the Rudolfinum to furnish free lodgings in that building to three hundred professors and teachers, of all nations and countries, who intend visiting the exhibition of 1873. The offer is made for the months of July, August, and September, and applies alike to the professors of royal academies and the teachers of any kind of public schools. Early application is to be made, giving in each instance the name, address, and teaching position of the applicant, locality of school or institution in which he is engaged, with the date and length of time of his desired occupancy of these free lodgings. The application is to be addressed to the administration of the Rudolfinum, 4, Moierhofgrasse, Vienna.

THE principal paper in the last number (Vol. ii. No. 4) of the

"Proceedings of the Bath Natural History Society," is a long address by the president, the Rev. Leonard Blomefield, F.L.S., F.G.S., on "Local Biology," containing many valuable hints as to the objects which members of such societies ought to have in view, illustrated by many interesting facts and recent observations in natural history. He shows how valuable the field work of local scientific societies might be made when intelligently and judiciously conducted, not only in collecting facts as to local biology, but in helping to solve many of the most important problems which are at present occupying the attention of biologists. The main qualification for efficient work of this kind is an intelligent and sharp look-out. Mr. Blomefield concludes his paper by some remarks on the faunas of Bath and Somerset. We are glad to see the address has been printed separately, and we would recommend it to the attention of all local scientific societies. The two other scientific papers in this number are on "Devonian Fossils from the Sandstones on the N.E. of the Quantocks," by the Rev. H. H. Winwood, F.G.S., and "The Geographical Position of the Carboniferous Formation in Somersetshire, with Notes on possible Coal Areas in adjoining Districts in the South of England," by J. McMurtrie, F.G.S., the latter illustrated by a well-constructed map.

We have received a wonderfully cheap pennyworth in the shape of a "Descriptive Guide to the Fossil Collection" of the Museum of the Leeds Philosophical and Literary Society. The pamphlet is interestingly written and well arranged, and contains a long and valuable list of useful books of reference on Palæontology.

The Third Annual Report of the Devon and Exeter Albert Memorial Museum, Schools of Science and Art, and Free Library, is altogether a very satisfactory one. Great facilities are offered for scientific study and laboratory practice, and these appear to be largely taken advantage of. The number of individual students during the current session is 89, and the subjects at present taught in the school are Mathematics, Theoretical Mechanics, Physical Geography, Geology, Acoustics, Light and Heat, Vegetable Anatomy and Physiology, Systematic and Economic Botany, Magnetism and Electricity, and Inorganic Chemistry with laboratory practice. According to the library statistics, a very large increase during the past year has taken place in the number of scientific books sought for, both in the consulting and lending libraries.

The following is the ephemeris of Tempel's Comet for the days named as, calculated by Mr. Hind for Greenwich midnight:—

1873	True R.A. h. m. s.	True N.P.D. ° ′ ″	Log Δ
June 20	16 14 50·1	111 18 19	9·91982
22	14 23·7	111 38 44	9·92529

6	16 15 5·3	113 53 30	9·97077

The additions to the Zoological Society's Gardens during the past week include a black Iguana (*Metopoceros cornutus*) from San Domingo, presented by Mr. John Dutton; two golden Tench (*Tinca vulgaris*), presented by Lord Herbrand Russell; two black Kites (*Milvus migrans*), presented by Mr. H. F. Blissett; two starred Tortoises (*Testudo stellata*) from India, presented by Capt. C. S. Sturt; a smooth-headed Capuchin (*Cebus monachus*) from Brazil, presented by Mr. J. A. Horsford; a Rhesus Monkey (*Macacus erythraeus*) from India, presented by Mr. G. Cork; an Entellus Monkey (*Semnopithecus entellus*) from India; four Sturgeon (*Accipenser sturio*); two American Rice-birds (*Dolichonyx oryzivora*); five horned Lizards (*Phrynosoma cornutum*) from Texas, purchased; a Lion (*Felis leo*) from Africa; a Collared Mangabey (*Cercocebus collaris*), a Diana Monkey (*Cercopithecus diana*), and a Moustache Monkey (*C. cephus*) from W. Africa, on approval.

SCIENTIFIC SERIALS

The *Journal of Botany* for May commences with a critical investigation, illustrated by a plate, by the editor, of the very common but badly understood Dock, *Rumex obtusifolius*, which is followed by two papers on the distribution of plants, Additions to the British lichen flora, by Rev. M. Crombie, and Additions to the flora of Berkshire, by James Britten. In this number is also the very useful annual list of the new species of phanerogamous plants described in periodicals published in Great Britain during the year 1872. The plate which now accompanies every number is a great addition to the value of this magazine.

In the June number the illustrated article is by Mr. W. P. Hiern, on *Physotrichia*, a new genus of Umbelliferous plants from Angola, from the Welwitschian collection. Mr. F. Townsend contributes a paper on a much controverted subject, some points relating to the morphology of *Carex* and other Monocotyledons. The short notes and queries are, as usual, not the least interesting portion of these two numbers.

Poggendorff's Annalen der Physik und Chemie, Supplement vol. vi., part. I. This number contains the first instalment of a series of researches on the volume constitution of solid substances; a lengthy paper in three parts, the first being introductory and theoretical, the second describing methods, and the third detailing results in the case of chlorides, bromides, and iodides.—Prof. Schwedoff of Odessa follows with an interesting paper, in which he establishes a correspondence between the propagation of electrical currents in thin conducting insulated plates and that of light rays in transparent media. A "ray of electricity" is represented by the line drawn from a pole to any given point of the body, and means simply the direction in which electrical "masses" (in the plate) are attracted to the pole or repelled from it. He shows that the intensity of such rays is inversionally proportional to distance from the pole; that they are reflected (it may be oftener than once), from the edges, the angles of reflection and incidence being equal; that they do not lose intensity by reflection, nor suffer change of sign. His theory and mode of experiment are illustrated by figures.—An article by Dr. Heinrich Schneebeli on bar-magnetlsm, contains a full and thorough investigation of magnetic moment in permanent bar-magnets, and more especially of the position of the magnetic pole; this is determined by two different methods which do not suppose a knowledge of the law of distribution of the magnetic fluid, and the results (closely agreeing), are applied in correction of the tangent galvanometer.—Carl Pape contributes a determination of the optical constants of blue vitriol, and Alexander Müller the first part of studies on chloride of iron solutions without change of aggregate state.—Among the extracted matter may be noted an article by Kohlrausch on the reduction of the Siemens unit of galvanic resistance to absolute measure, and one by Edlund on the nature of electricity, which has already appeared in English form.

The *Monthly Microscopical Journal* commences with an article by Dr. R. L. Maddox on an Entozoon with ova, found encysted in the muscles of a sheep, which he calls *Cysticercus oviparliens*. Then comes a very valuable paper on the development of the face in the sturgeon, by Mr. Parker, F.R.S., which, if followed by the description of a few more type-forms, will render the development of that complicated portion of the body, the head, one of the most easily understood sections of the vertebrate body. Mr. Joseph Needham gives a concise *résumé* of the methods employed for cutting sections of animal tissues for microscopical examination, in which he strongly advocates the method of freezing as "the simplest and most elegant mode" of obtaining sections of yielding tissues. Assistant-Surgeon Woodward describes how that a $\frac{1}{70}$th objective, sent to him by Mr. Tolles to test, gave a balsam angle of less than 80°, whilst a second, a $\frac{1}{8}$th of peculiar construction, having four combinations instead of three, gave the high angle of more than 100° when fully closed, and so exceeding the extreme limit assigned as attainable by Mr. Wenham. Mr. H. Davis gives further facts in support of the originallty of his theory respecting the survival of Rotifera after desiccation.

SOCIETIES AND ACADEMIES

London

Royal Society, May 8.—"Researches in Spectrum Analysis in connection with the Spectrum of the Sun."—No. II. By J. Norman Lockyer., F.R.S.

The observations in this paper are a continuation of those referred to in the previous communication bearing the same title. They deal (1) with the spectrum of chemical compounds, and (2) with the spectra of mechanical mixtures.

I. *Chemical Compounds.*

Several series of Salts were observed; these series may be divided into two:—1st, those in which the atomic weights varied in each series; 2nd, those in which the associated elements varied in each series. The following salts were mapped:—

$Pb\,F_2$, $Pb\,Cl_2$, $Pb\,Br_2$, $Pb\,I_2$; $Sr\,F_2$, $Sr\,Cl_2$, $Sr\,Br_2$, $Sr\,I_2$; $Ba\,F_2$, $Ba\,Cl_2$, $Ba\,Br_2$, $Ba\,I_2$; $Mg\,F_2$, $Mg\,Cl_2$, $Mg\,Br_2$ $Mg\,I_2$; $Na\,F$, $Na\,Cl$, $Na\,Br$, $Na\,I$.

The conditions of the experiments are described, the same aluminium cups, described in the first paper, were used, and the poles were arranged in such a manner that they could at will be surrounded with any gas or vapour. Hydrogen was used in some of these experiments; it was purified in the usual manner by drying, and freeing from traces of sulphuretted hydrogen, it was then passed over clean cut pieces of sodium, and admitted to the poles. An induction-spark from 5 one-pint Grove cells was used, the *circuit being without the Leyden jar.*

The lead compounds behaved (in air) as follows:—

The fluoride gave the eleven longest lines of the metal, but four were very faint.

The chloride gave nine lines; one of these is very short.

The bromide gave six lines, but one is a mere dot on the pole.

The iodide gave four lines distinctly and two as dots, one of which is scarcely visible.

It is pointed out that the decrease in length and number of lines follows the increase in the atomic weight of the non-metallic element, the lines dying out in the order of their length.

Barium was next experimented on, the same series of salts being used. A marked departure from the results obtained in the case of the lead compounds was observed especially in the case of the fluoride, its spectrum being much the simplest; in fact it consisted of only four lines. Strontium behaved like barium, and so did magnesium fluoride. This anomalous behaviour was found to be most probably due to the exceedingly refractory nature of these fluorides, all of them being quite infusible, and non-volatile in any spark that was used.

Sodic fluoride, sodic chloride, sodic bromide, and sodic iodide exhibited a behaviour exactly the reverse of that of lead, *i.e.* the iodide showed most of the metallic spectrum.

The difference between flame-spectra and those produced by a weak electric discharge are then discussed. Beads of the chlorides, &c., were heated in a Bunsen-gas flame; BaI_2 gave a "structure" spectrum (since proved to be due to the oxide) and the line 5534·5, by very far the longest metallic line of barium; the bead fused. The bromide behaved like the iodide, and so did the chloride, except that its spectrum was more brilliant. Baric fluoride gave scarcely a trace of a spectrum, the oxide structure being scarcely visible, and 5534·5 very faint indeed. The strontium salts follow those of barium, 4607·5, the longest strontium line appearing in conjunction with an oxide spectrum. The strontic fluoride, however, refused to give any spectrum whatever. These results are compared with those obtained with the weak spark, and it is shown that the difference is one of degree; *e.g.* baric bromide gives 25 lines in the spark; these are the longest lines. In the flame it gives but one line; but this is the longest of all the barium lines, and indeed very far exceeds all the others in length. When the flame-spectra are compared with those produced by the low tension spark, the spectra of the metals in the combination are in the former case invariably more simple than in the latter, *so that only the very longest line or lines are left.*

Some experiments made by Mr. R. J. Friswell to determine the cause of the similarity of the spectra of the various salts of the same metal observed in air are then given, the conclusion being that the spectrum observed is really that of the oxide.

Kirchhoff and Bunsen's, Mitscherlich's, and Clifton and Roscoe's prior conclusions on the points investigated are stated at length; and it is shown that the observations recorded, taken in conjunction with the determination of the long and short lines of metallic vapours, are in favour of the views advanced by Mitscherlich, Clifton, and Roscoe. For while the spectra of the iodides, bromides, &c. of any element in air are the same as stated by Kirchhoff and Bunsen, the fact that this is *not* the spectra of the metal is established by the other *fact, that only the very longest lines of the metal are present, increased dissociation bringing in the other metallic lines in order of their length.*

The spectra have been mapped with the salt in hydrogen; here the spectra are different, as stated by Mitscherlich, and *the metallic lines are represented according to the volatility of the compound, onry the very longest lines being visible in the case of the least volatile one.*

The following are the conclusions arrived at:—

1. A compound body has as definite a spectrum as a simple one; but while the spectrum of the latter consists of lines, the number and thickness of some of which increase with molecular approach, the spectrum of a compound consists in the main of channelled spaces and bands which increase in like manner. In short, the molecules of a simple body and of a compound one are affected in the same manner by their approach or recess, in so far as their spectra are concerned; *in other words, both spectra have their long and short lines,* the lines in the spectrum of the element being represented by bands or channelled lines in the spectrum of the compound; and in each case the greatest simplicity of the spectrum depends upon the greatest separation of molecules, and the greatest complexity (a continuous spectrum) upon their nearest approach.

2. The heat required to act upon a compound, so as to render its spectrum visible, dissociates the compound according to its volatility; the number of true metallic lines which thus appear is a measure of the dissociation, and doubtless as the metal lines increase in number the compound bands thin out.

Mitscherlich's obvervations, that the metalloids show the same structural spectra as the compound bodies is then referred to, and the question is asked whether the molecules of a metalloid do not in structure lie between those of elements on the one hand and compounds on the other.

These considerations are applied to solar and stellar spectra; the general appearance of the solar spectrum shows that in all probability there are no compounds in the sun.

Secchi's maps of a large number of stellar spectra are referred to as now indicating beyond all doubt the existence of compound vapours in the atmosphere of some stars; and it is suggested that the phenomena of variable stars may be due to a delicate state of equilibrium in the temperature of a star which now produces the great absorption of the compound and now that of the elemental molecules.

The second part of the paper deals with the mechanical mixtures. Maps of the spectra of alloys of the following percentages are given:—

Sn and Cd	percentages of	Cd	10·0, 5·0, 1·0, 0·15.
Pb and Zn	,, ,,	Zn	10·0, 5·0, 1·0, 0·1.
Pb and Mg	....	Mg	10·0, 1·0, 0·1, 0·01.

It is pointed out that the lines die out in the order of their length as the percentage becomes less, the shortest lines disappearing first; and that although we have here the germs of a quantitative spectrum analysis, the method is a rough one only, but that further researches on a method which promises much greater accuracy are in progress.

The bearing of these results on our knowledge of the reversing layer of the sun's atmospheres is then discussed.

Mathematical Society, June 12.—Dr. Hirst, F.R.S., president, in the chair.—The following papers were read:—"Some general theorems relating to Vibrations," Hon. J. W. Strutt; "Invariant conditions of multiple concurrence of three conics," Mr. J. J. Walker; "On a new form of Biquaternion, being the ratio of two systems of forces," Prof. Clifford; "A further note on geodesic lines," Prof. Cayley.—A paper by Prof. Wolstenholme, "The locus of the point of concourse of tangents to an epicycloid, inclined to each other at a constant angle," was, in the author's absence, taken as read.—A conversation ensued on the subject of Prof. Clifford's paper, in which the president, Prof. Cayley, and Mr. S. Roberts took part.

Geological Society, May 28.—Prof. Ramsay, F.R.S., vice-president, in the chair. The following communications were read:—"The Glaciation of the northern part of the Lake-district," by J. Clifton Ward. The author stated the leading questions to be settled by his investigation of the northern part of the Lake-district as follows:—The fact of the glaciation of the district being granted, and of this he adduced abundant evidence, the questions that arose were whether the glaciating agent worked from north to south, whether it came from within or from without the district, and finally, whether the agent was floating ice, a system of local glaciers, or an unbroken ice-cap. As the result of his investigation he maintained that there is no evidence that a great ice-cap from the north ever swept over this district. The ice-scratches trending along the

principal valleys, but sometimes crossing watersheds, indicate a great confluent glacier-sheet, at one time almost covering a great part of the district, the movement of which was determined by the principal water-shed of the Lake-district. In the part of the Lake-district under consideration the ice, during its increase, carried forward, from south to north, a great quantity of rocky material. There are no signs in the district of the occurrence of mild periods during the epoch of primary glaciation, but the author thought that the climate had probably become moderate before the great submergence of the land commenced. The author noticed the effect of the submergence upon the results of previous glacial action, and maintained that when the land had sunk 800 or 900 ft. there was a recurrence of cold, and boulders were transported by floating ice. Until the submergence reached 1,500 ft. there was no direct communication between the northern and southern halves of the Lake-district except by the straits of Dunmail Raise. From the directions which would be taken by the currents in the sea at this period, it would appear that boulders may then have been transported by floating ice in some of the same directions as they had previously been carried by glacier-ice. The extreme of submergence appeared to have been about 2,000 ft. The author further maintained that on the re-elevation of the district there was a second land-glaciation, affecting the higher valleys and clearing them of marine drift.—"Alluvial and Lacustrine Deposits and Alluvial Records of the Upper Indus Basin," by Frederic Drew. The author said that he felt the necessity for a careful classification of the phenomena of alluvial deposits, for the want of recognition of the different kinds was likely to lead to incorrect deductions; the classification he proposed was the following:—I. *Loosened material*, which consisted of disjointed rocks or loose angular stones, sometimes mixed up with mud, which had been separated and disintegrated, but since that had remained *unmoved*. II. *Taluses*, the substance of which had fallen by its own weight, and not been transported by streams. These were the great heaps of angular matter that were found at the foot of cliffs, with a slope generally of near 35°. A special form was the fan-talus, which occurred where the falling matter had either originated from, or collected to, one spot, from which again it spread, and made a partial cone of the same slope as the ordinary taluses. III. *Alluvial Fans.*—These were the fan-shaped extensions of alluvial or torrential matter that spread out from the mouths of gorges, where these debouched into a more open valley. They were in form cones of a low angle, commonly 5° or so; they had accumulated by layer after layer on a cone-shaped surface, as shown by the radial sections exhibiting layers of a straight slope, and the chord sections showing curves, which were by the theory hyperbolas. Many complicated phenomena were produced by the denudation of these fans, and the production of secondary ones, some of which were illustrated by diagrams. IV. *Alluvium*, which was defined as a deposit which sloped down the direction of the valley of the stream which had made it, and did not appreciably slope or curve over in a direction at right angles to that. With regard to the country in question, there was evidence of a succession of three states:—1st, The cutting of the valleys. 2nd, The accumulation of alluvial matter. 3rd, The cutting down of the streams through that alluvial matter. Accumulation denotes an excess of supply of material from the rocks (by disintegration) over what can be carried away by the streams. Denudation, or the cutting down of the streams through their alluvium (the lowering of their beds), denotes a deficiency of supply of material from the rocks as compared with the transporting power of the streams. Hence the author inferred that the period of great accumulation of these alluvial deposits was one of great disintegration of rocks, one of intense frost; in other words, it was the Glacial period, and that the denudation occurred when the cold lessened, and there came to be a smaller supply of disintegrated material. The connection of various glacial phenomena with the alluvium, such as the one described above, was taken to corroborate the inference that the greater deposits were made during the Glacial epoch.

Geologists' Association, June 6.—Mr. Robert Etheridge, F.R.S., vice-president, in the chair.—"On Ammonite Zones in the Upper Chalk of Margate, Kent," by Mr. F. A. Bedwell. The author described, and showed by sections, the exact positions in the cliffs to the east and west of Margate, of fifteen large Ammonites, twelve of which lie between the Flagstaff and the Cliftonville Hotel, a space of about half a mile, and some of them exceed three feet in diameter. All these twelve are in a bed closely approximating to an exact parallel with a faint line of nodular flints which undulates over this part of the cliff and are at a constant distance of eight feet below that line. These facts indicate the following (1) The presence of an Ammonite zone, and of (2) a true sea floor. (3) The parallelism of this with the horizontal flints, and (4) that all the horizontal bands of flint must be assumed to have been aggregated before the chalk moved. Particulars were also given of three other beds of Ammonites, one to the west of Margate, another forty feet below that first mentioned, and a fourth at Pegwell Bay, at the top of the cliff near the landing-stage. The first and second were conjectured to be identical, and also the third and fourth. Specimens from the first and second beds were respectively identified by Mr. Etheridge as *A. leptophyllus* and *A. Lewesiensis*. Similar beds elsewhere were referred to, but details could only be given of one. This is to be seen at low water near the Black Rock at Brighton. A remarkable bed of continuous solid flint, three or four inches thick, occurs round and under the Isle of Thanet. Between the Foreland and Pegwell Bay it is in the upper part of the cliff, sinks below the shore at Pegwell Bay and Kingsgate, rises again to the west at the back of Margate Harbour but disappears immediately, appears again to the south, as pointed out by Mr. Whitaker in his Geology of the London Basin, at Cap Point near Walmer, and again at Shepherd's Well Station, 10 miles inland, where it is surmounted by the soft almost flintless chalk of Margate, and finally it was known throughout the island by the well diggers. This positive testimony of coincident and uniform flint aggregation over so large an area appeared to be an important fact in its bearing on the origin of flint. Mr. Bedwell stated that he had found the ammonites entirely by trusting to the zone of life theory insisted on by Mr. Caleb Evans in his paper on the Chalk (Geol. Assoc. 1870), and had failed to find them until he had selected the faint line of flints as a datum line and worked from that. He advised all young students of the chalk to examine a cliff in true horizons and not in a mere indiscriminate effort to make a large bag of specimens, to record carefully the exact chronological order of each fossil extracted by referring it to a datum line as suggested by Mr. Caleb Evans, to keep in mind the time which may have separated the life history of two fossils though only distant a few feet from each other, and to try to correlate two sections of chalk rather by the succession of zones of life in each cliff than by a mere comparison of indiscriminately collected fossils. The author in conclusion urged the importance of allowing Nature to teach her own independent lessons at the cliff side, of supplementing Nature by books rather than books by Nature, and pointed out how easy it was for those with little knowledge of details to be of service to science by simple observation and following to its end one single thread and one only, and then laying the results before scientific men, leaving them to estimate the value of the information.

Royal Horticultural Society, June 4.—Scientific Committee.—A. Smee, F.R.S., in the chair.—A fruit of *Anona reticulata* was sent produced in the gardens of Sir Walter Trevelyan at Wallington.—A letter was read from Prof. Westwood, stating that some grubs which had been submitted to him as having completely destroyed some bulbs, proved to belong to *Merodon clavipes*, a very rare insect in England, and in this case probably introduced.—A Pelargonium of the variety Cleopatra was exhibited from the Chiswick Garden. It had produced trusses of flowers of its proper pink as well as others of its ancestral scarlet.—Dr. Gilbert made some remarks on the proposed use of chalk mixed with coal in furnaces for horticultural purposes. He said it was quite certain the chalk could not supply any heat; on the contrary, its conversion into lime involved a considerable loss of heat in order to effect the change. What the chalk did was to absorb the heat and radiate it out again, and pieces of broken fire brick would probably answer the purpose equally well. The mixture of these substances simply, so to speak, diluted the coal.—A fine specimen of fasciated asparagus was shown from Mr. Macmillan. It has been produced two years running apparently from the same plant.

General Meeting.—Viscount Bury, M.P., president, in the chair.—The Rev. M. J. Berkeley stated that he had recently seen in Denbighshire nectarine trees, the flowers of which usually produced five carpels instead of one. He commented on the effects of the late frost on the potatoes at Chiswick. Some were very much injured, while others had escaped altogether, and in some instances of two stems to one root, one had been killed back and the other not touched.

PHILADELPHIA

Academy of Natural Sciences, March 4.—Mr. Vaux, vice-president, in the chair.—Mr. Thomas Meehan exhibited a flower of *Bletia Tankervillia* (*Phaius grandiflora* of some authors), in which the dorsal sepal (or, as some authors contend, petal), had united with the column, and had been much retarded in its development accordingly. He said that he had several dozen of flowers produced in this way this winter, all, however, confined to separate spikes from those which bore the perfect flowers. It was usual to pass over these appearances as "monstrosities," but in truth the whole Orchid structure was little less than a monstrosity. He did not think as much had been made out of the changes of structure in orchids in the study of evolution, as might be, in consequence of the impression that these abnormal forms, as they were termed, were monstrosities, or the results of cultivation. There had been already on record accounts of changes in wild orchids more remarkable than many much dwelt on by many modern writers on development. He further remarked that, in examining closely the flowers of *Bletia Tankervillia* early in the morning, he found on the outside, at the base of the three exterior petals, a liquid exudation from a small gland. It was highly probable that these glands were rudimentary spurs, and that, if the course of nutrition which sustained the cohering power of an orchid could in any way be diverted before the final direction of form, each of these outer petals might take on some of the labellate character, with its attendant spur, which gave such a peculiar appearance to so many orchidaceous plants.

March 18.—The president, Dr. Ruschenberger, in the chair.—"On the Occurrence of an Extinct Hog in America."—Prof. Leidy exhibited the fragment of a lower jaw of a pig which Prof. Hayden had picked up, together with many remains of extinct mammals, in the pliocene sands of the Niobrara River, Nebraska. The specimen he viewed as of recent character, and not as a true indigenous fossil. Prof. Leidy remarked that he had never seen any remains of the hog which he could confidently view as true American fossils.—Prof. Cope stated that Dr. Hayden handed to him for determination some bones on a fragment of the Green River shale of the Eocene of Wyoming. They indicated a species of Anourous Batrachian, but as the individuals were not fully developed, he was not prepared to identify the genus. They constituted the first indication of this order in time; those previously known from Europe and India being all of Miocene age.

PARIS

Academy of Sciences, June 9.—M. de Quatrefages, president, in the chair.—M. Dupuy de Lome presented to the Academy, in the name of the Minister of Marine, the first number of the "Memorial of Marine Artillery" and its appendix, "The Artillery Remembrancer." These are published for the use of French naval officers, and contain an immense amount of information on the armament of foreign ships of war. Great space is devoted to English naval matters, and the Memorial is well worthy of the attention of our own naval authorities.—The following papers were read:—Researches on new propyl derivatives, No. 2, by M. A. Cahours. The glucinum, silicon, and boron compounds of propyl were described.—On normal and abnormal speech, by M. Bouillaud.—On the intervention of atmospheric nitrogen in the phenomena of vegetation, by M. P. P. Dehérain. The author described some experiments which showed that, in the presence of ammonia, glucose absorbs nitrogen from the air.—On the multiple causes which provoke the fall of lightning, by M. W. de Fonvielle.—On the theory of the spots and the dark nucleus of the sun, by M. E. Vicaire. The author replied to M. Faye's recent answer to him; he thinks that Respighi's observations quoted by M. Faye tend to support his views rather than those of that astronomer, *i.e.* that the absence of the chromosphere over the spots is due to a cessation of the emission of the gases of which it is composed, and not to their being swallowed up by a cyclone.—Researches in spectrum analysis in relation to the spectrum of the sun, by Mr. J. N. Lockyer. This was a letter to M. Dumas giving an account of the author's late paper read before the Royal Society.—An answer to M. Raynaud's late note on the resistance-maxima of magnetic coils, by M. Th. du Moncel.—On the relation between electric and capillary phenomena, by M. G. Lippmann.—On the boiling points and molecular volumes of the chlorinated isomers of the ethylic series, by M. G. Hinrichs.—On ethylacetylene formed by synthesis, and on its identity with crotonylene, by M. L. Prunier. The author has synthesised this body by passing equal volumes of ethylene and acetylene through a porcelain tube heated to dull redness.—On the synthesis of phenyl-allyl, by M. Chojnacki. The author obtained this body by acting on a mixture of equal weights of benzine and iodide, or bromide of allyl, with $\frac{1}{8}$th of its weight of powdered zinc.—On the combinations of titanic chloride with the ethers, by M. Demarçay.—On phenyl-cyanine, by Mr. T. L. Phipson.—Note on M. Mène's paper on the preparation of ammonic sulphate from nitrogenous waste, by M. L'Hote.—On the estimation of phosphoric acid in manures, coprolites, and fossil phosphates, by M. Ch. Mène.—Mineralogical note on the dibasic plumbic sulphate of l'Ariége, by M. E. Jannettaz.—On the affinities of *Etheostomata* (Agassiz), by M. L. Vaillant.—Magnetic observations, by M. Diamilla-Muller.—Spectroscopic researches on the fumerolles of the eruption of Vesuvius of April 1872, and on the actual state of that volcano, by M. L. Palmieri. This was a very short extract from a letter, the only points being that thallium and boric acid are found in the sublimates from these vents, and that since the eruption the mountain has exhibited a state of abnormal quietude.

DIARY

THURSDAY, JUNE 19.

ROYAL SOCIETY, at 8.30.—On the Fossil Mammals of Australia, Part IX. Family Macropodidae: Prof. Owen, C.B.—On the Nature and Physiological Action of the Poison of Naja Tripudicans, and other Indian Venomous Snakes: Dr. Fayrer and Dr. Brunton.—Researches in Circular Solar Spectra Applied to Test Residuary Aberration in Microscopes and Telescopes: Dr. Royston-Pigott.—On the Structure and Development of the Skull in the Pig (*sus scrofa*): W. K. Parker.—Results of the Comparisons of the Standards of Length of England, Austria, Spain, United States, Cape of Good Hope, &c.: Lieut.-Col. Clarke.—On Comparative Vegetable Chromatology: H. C. Sorby.

SOCIETY OF ANTIQUARIES, at 8.30.—On Further Excavations at Silchester: Rev. J. G. Joyce.

LINNEAN SOCIETY, at 8.

CHEMICAL SOCIETY, at 8.—On the Influence of Pressure upon Fermentation. Part II.: Horace Brown.—Researches on the Action of the Copper-Zinc Couple on Organic Bodies, III., and on Normal and Iso-Propyl Iodides: Dr. J. H. Gladstone and A. Tribe.—On Cymenes from different sources optically considered: Dr. J. H. Gladstone.—On the Action of Bromine on Alizarine: W. H. Perkin.—On some Decompositions and Oxidation Products of Morphine and Codeine Derivatives: E. L. Mayer and Dr. C. R. A. Wright.—On the Decomposition of Tricalcic Phosphate by Water: R. Warrington.—On a new Tellurium Mineral, with Notes on a Systematic Mineralogical Nomenclature: J. B. Hannay.—Communications from the Laboratory of the London Institution, No. XII.:—On New Derivatives of Cresol: Dr. H. E. Armstrong and C. L. Field.

NUMISMATIC SOCIETY, at 7.—Anniversary.

FRIDAY, JUNE 20.

MEDICAL MICROSCOPICAL SOCIETY, at 8.—The Pathological Relations of Diptheria and Croup: Jabez Hogg.

MONDAY, JUNE 23.

GEOGRAPHICAL SOCIETY, at 8.30.

WEDNESDAY, JUNE 25.

SOCIETY OF ARTS, at 4.—Anniversary.

GEOLOGICAL SOCIETY, at 8.—On Six Lake-basins in Argyllshire: His Grace the Duke of Argyll, K.T., F.R.S., President.—Description of the Skull of a Dentigerous Bird (*Odontopteryx toliapicus*, Owen), from the London Clay of Sheppey: Prof. Richard Owen, F.R.S.—Contribution to the Anatomy of *Hypsilophodon Foxii*, Huxley: J. W. Hulke, F.R.S.—On the Glacial Phenomena of the Long Island, or Outer Hebrides: James Geikie.—On Fossil Corals from the Eocene Formation of the West Indies: Prof. P. Martin Duncan, F.R.S.—Note on the Lignite-deposit of Lal Lal, Victoria, Australia: R. Etheridge, Jun.

THURSDAY, JUNE 26.

SOCIETY OF ANTIQUARIES, at 8.30.

THURSDAY, JUNE 26, 1873

THE ENDOWMENT OF RESEARCH

I.

THERE are not wanting signs that ere long the whole question of the present condition of research in this country, and of its amelioration, will undergo a complete discussion. Those who are best acquainted with this condition, and the position occupied by England at the present moment in the Science of the world, will be the first to acknowledge the importance of general attention being directed to the subject.

When the matter comes to be considered by minds free from the trammels alike of tradition and of prejudice, it will doubtless be found strange that such a fundamental question should have waited so long before it should have asserted itself; on the other hand, it is perfectly clear that many who are even now considering it have utterly failed to grasp it as it will have to be grasped.

This lack of clearness in the appreciation of the vast bearings of the question is quite pardonable, and is, doubtless, to a large extent, the natural consequence of the manner in which physical science has been added on to, the older knowledge. It would seem, however, that a mere statement of a few fundamental positions should clear the view. These positions, most fortunately, are rapidly asserting themselves.

First, we have the generally acknowledged fact that a nation's progress depends upon its Science. Science, in fact, is the engine which must be as ever active in peace as the cannon's mouth is in war, and a nation may just as safely neglect one as the other.

This brings us to the second position. Does England as a nation pay as much heed to the one as the other? or as much as other nations? To ask this question is to answer it. England as a nation does next to nothing for this peace armament, and on all hands it is acknowledged that the nation's progress from this point of view is in great danger, because the decline of research in England, not only relatively, but absolutely, is so decided, that it is already a matter of history. We have long ago in these pages referred to Dr. Frankland's evidence on this point; he is the acknowledged head of chemical science in this country and should surely know; and other men who cultivate other sciences have expressed the same opinions with regard to them.

To what then is this decline to be attributed? The reply to this question brings us to the third point. There is absolutely no career for the student of Science, as such, in this country. True scientific research is absolutely unencouraged and unpaid. The original investigator is of course the man here intended, not the man who turns Science into a means of livelihood, however honourable, either as a teacher or a manufacturer.

There can be no doubt that to this state of things our present condition is to be ascribed, and this point is, according to us, the key of the whole position. A glance at the condition of things in France and Germany will strengthen our view. Why was Germany till lately the acknowledged leader in all matters connected with the advancement of knowledge? Because there were no such brilliant and highly paid careers open there as here to those who choose politics, the bench, the bar, or commerce, in preference to Science. And what is happening there at present? a decline visible not alone to the far-sighted, because Germany is getting rich as England has long been rich. Why is France now endowing research on a large scale, and even proposing that the most successful students in her magnificent Polytechnic School should be allowed to advance Science as State servants? Because in France there is a government instructed enough to acknowledge that a decline of investigation may bring evil to the State, and that it is the duty of the State to guard against this condition of things at all cost, this condition till lately, there as here, being that outside of the State service, and outside of the professoriate, no means of existence are provided for a student of Science; hence men of the most excellent promise are yearly lost to research, which undoubtedly also is the case with us.

What course then does it behove us to pursue in this country, in order that Science may take up its true position in our midst?

Here again opinion is rapidly forming itself. It is obvious to all who have thought about the matter, that it is absolutely indispensable that an employment, necessary for the public good, which is neglected to the State's detriment because in itself it does not bring in a livelihood, should be artificially supported, and artificially supported at the public expense. It would be quite justifiable, both from an economical and also a political point of view, to provide for the needs of knowledge out of the taxation of the country; because the taxpayer gets back his *quid pro quo* for the taxes he pays in the form of the amelioration of the conditions of living, as he gets it back in the form of security and good government.

It will probably be a considerable time before this truth is brought home to the public mind so completely as to render possible any large grant of national income for this purpose; but there are not wanting indications that statesmen of all parties are awakening to its reality, which in point of fact has long been conceded in principle. Still, such a source of support for Science to any very large extent must appear, even to the most sanguine, a thing of the future.

The area of knowledge will probably, in the future, increase beyond the means of any artificial support less than the national one; but perhaps it cannot be said that this state of things exists at present.

What, then, are we to do in the mean time? Have we no means which are at hand and immediately available, which may suffice to support the present claims of knowledge, without drawing too extensively upon the long-suffering or the intelligence of the taxpayer?

We have the means, if we will only employ them—nay more, some of them are now, for the most part, lying idle—of not only supplying all the needs of the physical and other sciences, but of supplying them magnificently. To mention no other sources of supply there is the Patent Fund, and the endowments of the colleges of the old Universities.

As to the Patent Fund, it is not too much to say that a

large part has been derived from the application of the abstract truths of physical science to the requirements of ordinary life, and that therefore the needs of physical science would be properly provided for out of it.

As to the College Endowments, whichever way we look at them, either as private bequests, as they are at length ceasing to be regarded, or as public funds, the conclusion is the same: their proper destination is the support of learning and Science.

If we look upon them as private bequests, and interpret the wills of founders and benefactors on the usual *çi-près* principle, we should be right in devoting to investigation of facts at first hand the funds which were left by the far-seeing men of the time of the revival of letters for the support of book-learning, which at that time occupied the place of modern Science. That they so regarded the aim of these bequests is shown, amongst other things, very remarkably by the universal annexation to the enjoyment of them of the condition of residence within the Universities. When the whole, or the major part, of the materials of investigation was enshrined in libraries, to insist that a man should remain where libraries were was to insist that he should remain in his workshop.

If on the other hand we are to regard these endowments as public funds, as is now generally agreed, is it right that such public funds should be consumed either in educating those who are practically as well able to pay for their own education as those who now receive a similar one at, say London University, an institution which is not aided by the State; or in supplying a life-maintenance to a considerable body of able young men, in return for passing a good examination at the outset of life?

It is well known that the ordinary Fellow of a college does not dream for a moment that he has any duties towards knowledge or Science. He regards the public money which he enjoys as a portion in a freehold estate, to enable him to tide over the uncertain years which come at the commencement of the ordinary professional career, the brilliant rewards of which we have shown to be the great cause of the decline of Science in this country, because they enable the practical life to outbid in attractiveness the laborious but most necessary pursuit of truth.

CHAUVEAU'S ANATOMY OF DOMESTICATED ANIMALS

The Comparative Anatomy of the Domesticated Animals. By A. Chauveau. Translated and edited by G. Flemming, Vet.-Surg. R.E. (J. and A. Churchill.)

FOR a long time there has been a great want felt by veterinary surgeons of a first-class work on the anatomy of the horse and other domestic animals, to be to them as valuable and trustworthy a book of reference as Quain and Sharpey's Anatomy is to the student of human anatomy. This feeling has induced Mr. Flemming to undertake the very arduous and considerable task of translating from the French the generally esteemed "Traité d'Anatomie Comparée des animaux domestiques" of M. Chauveau. The high position held by the Veterinary School of Lyons, and the great scientific reputation of its Professor, are sufficient guarantee for the excellence and accuracy of the original work before us, so that it will be unnecessary to enter into a detailed criticism of it: it will therefore be our chief duty to consider the manner in which the translation has been performed.

There are, however, one or two points to which we should like to draw attention in the work itself. First respecting the nomenclature of the lobes of the liver in the horse, Prof. Chauveau, as do most of the authors on the same subject, incorrectly calls the Caudate lobe the Spigelian. This error was clearly pointed out by Prof. Flower in his Hunterian Lectures last year, when he conclusively proved that the free, ear-shaped lobe, which is situated to the right of the vena portæ in the horse, rhinoceros and tapir, is the caudate and not the spigelian lobe. This last is represented by a long attached transverse ridge of hepatic tissue, situated further to the left. Again, it is not clear why the protometra is said to be incorrectly termed the *uterus mascululinus*, for it is certainly not a gland in the ordinary sense of the word, and is as certainly the rudiment of the duct which developes into the uterus in the female. In the paragraph on the small horny plates, called "chesnuts," found on the lower third of the inner face of the forearm and at the upper extremity of the inner face of the metatarsal bone of the horse, the author remarks that "In solipeds, the chesnut is the representative of the thumb." That such is the case is, to say the least, extremely doubtful particularly in any member of the class Ungulata; and from the fact that in the rhinoceros and tapir the second digit is perfectly developed, these epidermic appendages would be most probably larger in them than in Horse, if they represented the pollex and hallux; however they are altogether absent. That these horny plates in the fore-limb are situated above the carpus, is likewise not in harmony with their representing the thumbs.

Respecting the translation, which considering the size of the volume, must have been a very serious undertaking, the reader will, in the majority of cases, learn as correctly and as easily as from the original French. A perusal of several portions of the work seems to indicate that the translation has been performed by more than a single hand, for in some portions it is not so good as in others, and different words are employed to express the same one in the original. If there is any fault to find, it is one which may be considered by some to be rather an advantage than not, namely, that the rendering is too literal. A verbatim translation is in some cases not capable of giving the full force of the author's meaning in scientific as well as in other subjects, each language having an idiomatic phraseology of its own. For instance, the middle of the diaphragm may be correctly termed in French "le centre phrénique," but it is more than perplexing to comprehend at first sight what is meant by "the phrenic centre." The cavities of the heart (*les poches*) are not called "pouches" by English anatomists, and the colon is succulated (*bosselé*), not "bosselated;" this latter word is not to be found in some, perhaps not in any standard dictionaries. The stylo-glossus muscle does not "respond" (*il repond*) but corresponds "with the mylo-hyoid outwardly and the genio-glossus inwardly." The large colon of the horse is said to be fixed by adherence to the "cross of the cæcum;" we do not know what the cross of the cæcum is,

but the angle or bend (*crosse*) can be easily understood; in other places this word is correctly translated. Several minor errors in which nouns are rendered as adjectives and sentences are incomplete, will be no doubt corrected in a second edition.

Mr. Flemming has made some modifications in the general plan of the work, which will decidedly render it more useful to English readers. The descriptions of the anatomy of the ruminants, as well as those of the cat, dog, and birds, are in small type, so that it is not at all difficult, by omitting all but the large type, to study the bones, muscles, and nerves of the horse, without having to sift these out from the much larger mass of information respecting the other animals, as has to be done in the French edition. He has also added many notes, which in most cases bear on practical points in veterinary art; and he has omitted, wisely we think, the paragraphs of the original, which have reference to the dromedary and rabbit. Several of the unnecessary illustrations of human dissections, which can be found in many other works on the subject, have been omitted, and they have been replaced to advantage by others which further illustrate that of the horse, and also the recent advances in our knowledge of the structure of the tissues of the animal body.

Students of human anatomy are too apt to think that anthropotomy is the only subject of the kind which has been worked out thoroughly and in detail, but a glance at the book before us will soon remove that impression; and we are convinced that no one who has made any progress in a medical education could more profitably employ an occasional spare hour, than by a perusal of parts of this translation by Mr. Flemming of M. Chauveau's most excellent treatise.

RECENT ARITHMETICS

Arithmetic in Theory and Practice. By J. Brook-Smith, M.A., LL.B. (Macmillan, 1872.)

A Treatise on Arithmetic. By J. Hamblin Smith, M.A. (University Press, Cambridge, 1872.)

Figures made easy. A First Arithmetic Book. By Lewis Hensley, M.A. (Clarendon Press Series, Oxford, 1872.)

Notes on Arithmetic and Algebra. By the Rev. S. E. Williams, M.A. (Cambridge: J. Hall and Son, 1872.)

MOST persons engaged in tuition have often this critical question proposed to them, "Whose arithmetic do you recommend?" and as almost every teacher of mathematics fancies he has something new or varied to say on the subjects he has long taught, many rush into print, and thus submit their claims to consideration to a wider circle than that they have hitherto addressed. "As many arithmetics as teachers of the science," is perhaps as true a doctrine as that which applies to men and their opinions, certainly the writing of treatises on the subject has not of late years got into disfavour with the body referred to, and a second edition of De Morgan's Arithmetical Books, would show a considerable increase in number of authors if brought down to the present date. Every year sends forth a heap of candidates for the public favour. On the whole perhaps arithmetic has been very fairly treated; most of the treatises that have come under our own eyes have possessed something to recommend them. We have grouped together for our present consideration some of the most recent works on the science. Without doubt the first book on our list is entitled to the place of honour; it is, we think, the best work that has appeared for some years, the only work claiming to be ranked on the same high platform with it, being the "Arithmetic Theoretical and Practical," by W. H Girdlestone, M.A. (Rivingtons, 1870): the two have much in common. In this treatise the leading propositions are discussed and reasoned out in a lucid and accurate manner; the fundamental principles are clearly stated, and there is a valuable collection of examination papers for the student to try his powers upon. The writer is a disciple of De Morgan, to whom, as well as to other eminent writers on Arithmetic, he acknowledges his indebtedness. The book is quite up to approved modern standards, as it gives contracted methods of work, and treats of the metric system, and of the application of per-centages. It needs no further commendation, and after stating that it is a good *practical* work, we advise a student in want of a good treatise, to get this, and make it part and parcel of his mental furniture. The "get-up" of the book, its external dress, its inner garniture, is not merely neat but positively elegant, and possibly indicates the high interest the author takes in the subject upon which he has written so well.

Mr. Hamblin Smith's work calls for no special comment: the ability with which the author has written on other subjects will doubtless induce many to purchase the book. It is hard to write anything new on so hackneyed a theme, and there are few who have been able to raise the treatment of it above the ordinary fair orthodox level. We believe it to be a sound book, but it could have been dispensed with (especially with our first considered work in the field) except as it serves to fill up a niche in a connected series of text-books. The writer in this case also aims at teaching not so much *rules* as *principles*, and he rightly treats the so-called *rule of three* by the rational method now so generally adopted. The book may be recommended as a school-book, and this is probably the object the writer had in view. There is a copious collection of examination papers, which occupies nearly one-sixth of the whole work.

The third work on our list is concerned with much lower ground than the two former; it is written for mere infants, so to speak, in the science—it is an A B C: the receiving vessels are small and their capacity consequently for acquiring such new ideas as are presented to them at the outset of their inquiries also small; our author, with the ability only acquired by careful thought and experience, prepares right food, and not too much of that, for each lesson. In forty lessons the pupil is carried from "first notions of counting" to "division of fractions." With careful oral teaching we believe the book to be well adapted for the end aimed at. It is printed in the effective style of the "Clarendon Press" Series, and is further recommended by its cheapness.

The "Notes" presuppose a general knowledge of the subject, and give for the most part no explanation of the rules. The book is intended to act more as a "refresher" than as an "instructor," yet in the addition, multiplication, and division of recurring decimals, together with

the history of the calendar, the author has gone into a little more detail. To these "Notes" have been subsequently added some useful "Notes on Algebra." For the object aimed at the book is very fairly adapted. Some few further notes which will readily occur to the majority of teachers can be easily furnished to pupils using the "Notes" for insertion, in addition to the printed ones.

We have not tested the accuracy of the solutions given in the works we have here examined.

OUR BOOK SHELF

Official Guide-book to the Brighton Aquarium. By W. Saville Kent, F.L.S., F.Z.S. (Brighton, 1873, price 6*d.*)

THE Brighton Aquarium is without doubt the largest and most extensive of the buildings which have been erected of late years for the exhibition of aquatic animals. It also possesses the advantages of being at the seaside, and at the same time conveniently placed for access to the multitude of sight-seers. Though a large sum of money was spent upon its construction, we have been informed that good dividends are paid to the shareholders, and it would seem that the institution shows every symptom of favourable progress. In our eyes the issue of the present guide-book is a very welcome proof that Science will not be entirely neglected in the endeavours to attain material prosperity. Mr. Saville Kent's guide-book is drawn up with a strictly scientific method, but at the same time a large amount of popular information is given in it, and it is well adapted for the purpose for which it is intended.

The higher vertebrata of the Brighton Aquarium are at present but few in number, consisting only of porpoises, representing the order *Cetacea,* and the common seal, exemplifying the marine section of the Carnivora, and it is not likely that the representatives of these orders will be much increased in number. But the class of fishes is, on the other hand, very well represented, the Brighton Institution containing the best living series of these animals that has ever yet been brought together, and one that, as our weekly record of its progress shows, is continually increasing both in number and in variety. Mr. Kent's guide-book furnishes the visitor with a short account of the principal facts that are known concerning the life-history of each of these fishes, and cannot fail to add greatly to the instruction to be derived from a visit to the Aquarium. After the fishes, which certainly form the leading feature in the Brighton establishment, and consequently the principal topic in the guide-book, Mr. Kent turns to the Invertebrate division of the animal kingdom, and gives a general sketch of the five groups into which it is now usually separated, and of their principal representatives in the Aquarium. This portion of the guide-book, we think, requires further development, and will doubtless receive it in a future edition. We also beg leave to suggest that a few illustrations in the way of woodcuts would be a valuable addition to the handbook, and would, moreover, be likely to assist very materially in extending its sale. The only illustration in the edition now before us is the ground-plan of the building, given as a frontispiece to the work, and showing the arrangements of the different tanks and rooms. Figures of some of the more remarkable inhabitants of the tanks would, in our opinion, render Mr. Kent's book more attractive to the general visitors, and more useful to the scientific student.

Chemistry for Schools. By C. Haughton Gill. With 100 illustrations. Second edition. (London: Edward Stanford, 6 and 7, Charing Cross, 1873.)

MR. GILL's little manual is intended either for private study or for class-teaching, and has special reference to the requirements of those who have to learn the small modicum of chemistry required for the matriculation examination of the University of London. He has indicated the chapters necessary for the latter by a †, an act which we cannot at all approve. Surely, if even so light an examination as the one in question has to be undertaken in what may be to some a distasteful study, it is better to know too much than too little, and Mr. Gill's little book is not such a very dreadful treatise that one need be afraid of reading it through. If the examinations are to mean nothing more than the "getting up" of a set of special chapters written for the purpose, they had better by far be abandoned at once. With this exception we have little fault to find. Great care has been taken in arranging and systematising the work, though this has been pushed rather far—the word "acid," for instance, being almost banished. The great merit of the book is, however, to be found in the very admirably-selected questions placed at the end of each chapter: we feel sure that anyone conscientiously endeavouring to understand and work these out would learn more, and that more thoroughly, than he would by a vast amount of desultory reading and rambling through of larger works. We would say to any candidate for the London matriculation, "Let him neglect Mr. Gill's advice about the marked chapters, and work conscientiously through the book."

Report of the Rugby School Natural History Society for the Year 1872. (Rugby: Billington, 1873.)

WE are sorry that the first words of this Report are words of complaint at the small number of real workers among the numerous members of this society; some of the Sections we regret very much to be told, are either deserted or inactive. We hope no such complaint will be called for next year, and that the new regulation as to membership may be of service as a stimulus to work among the younger associates; by this new rule the number of members is henceforward limited to 15, for the purpose of making election to membership a real distinction. To judge from the number and value of the papers in the Report, there are, after all, not a few really good workers among the members. Of the various selected papers and reports one-half are by members who were actual pupils of the school at the time they were written. B. R. Wise's paper "On the Earliness of the Season" (1872), shows the possession of a power of observation which, if carefully cultivated, ought to produce good results. The same may be said of A. G. Burchardt's paper on "The Work of the Anatomical Section," which contains an account of some of the animals found in the Rugby district, and some very useful directions on the preservation of specimens. E. J. Taylor's account of "A Visit to Norway" is interesting, and shows the author can make use of his eyes. L. Maxwell's essay on "Spectrum Analysis," well deserves the Society's Prize, which was awarded to it: the author shows that he possesses a clear idea of the nature of Spectrum Analysis, the principles on which it is based, and the many valuable purposes it is calculated to serve. It is accompanied by some rough but intelligible drawings of various absorption spectra. The second prize was awarded to an intelligent paper by H. N. Hutchinson on "Motive Power," in which the author describes and illustrates various substitutes for coal as generators of motive power, including an ingenious flux motor, or tidal engine. Among other interesting papers we would mention the valuable observations on *Hippocampus brevirostris,* by the Rev. T. N. Hutchinson; and some very curious facts as to protective mimicry in spiders, communicated by the Rev. C. W. Penny. From the Astronomical Report, by Mr. Wilson, we learn that a large amount of good work is being done, especially in solar observation. Appended to the report are Messrs. Lockyer and Seabroke's paper "On a New Method of Viewing the Chromosphere;" and a report on the November Meteors, by L. Maxwell. The Meteorological Observations seem to have been regularly and carefully taken, though we hope there will be more to report in the

Zoological Section as the result of the present year's work; the anatomical department of this section has, however, made a fair start under the direction of the late member, Mr. A. G. Burchardt. W. B. Lewis's Report of the Geological Section, with accompanying plates, shows there has been some activity in this department. A. F. Buxton's Entomological Report consists of a complete list of the Lepidoptera which have been noticed within eight miles of the School Close. Under Mr. Kitchener's, the President's, guidance, some good work has been done in the Botanical Section, though the workers seem to be few. Appended to the report of this section is an abstract of two papers by Mr. Kitchener on a Pelerian form of *Linaria vulgaris*. On the whole, the Report of this Society's work for 1872, is one of which there is no reason to be ashamed, and we hope that each year will add to the number of those who take an active part in the work. From many scientific societies it is not advisable nor often expedient to exclude non-workers, but in such societies connected with schools, it should be insisted on that every member be an active worker: only thus can they completely serve the purpose for which they are established.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Dr. Sanderson's Experiments and Archebiosis

The letter by Dr. Sanderson, in last week's Nature, contains an interesting and important confirmation of my experiments, which I was very glad to see. There are two or three points, however, which seem to require some comment.

In the first place the flasks and retorts after exposure to the heat were kept only from three to six days, before they were submitted to examination in order to ascertain whether fermentation had or had not taken place. But in cases in which fluids are exposed to heat for a long time, or are exposed to higher temperatures, the process of fermentation is almost invariably delayed and also modified in intensity. It must not therefore be supposed that fermentation would not have taken place at all in certain of Dr. Sanderson's flasks, simply because it had not occurred within four, five, or six days.

Secondly, Dr. Sanderson thinks his present experiments enable him to say that the particular fluid with which he experimented is not prone to undergo fermentation within six days, after it has been heated to a temperature of 100·92° C. I would ask Dr. Sanderson, however, whether he has been careful to observe the precise temperature attained by an infusion boiling rapidly in a flask from which the steam can find exit only through a capillary orifice—as in the experiments which we performed together?

Thirdly, I think it very desirable that Dr. Sanderson should state definitely to the scientific world what precise meaning he wishes to convey by his emphasized use of the word "*chance*" in the concluding paragraph of his letter. There seems a little ambiguity in his use of the word, which is the more to be regretted, since it occurs in the statement of an inference—where freedom from all possibility of misconception is so eminently desirable.

University College, June 23

Spectrum of Nitrogen

In a letter to Nature (April 17th), Mr. Stearn throws some doubts on the accuracy of my experiments regarding the spectrum of nitrogen. I shall take the earliest opportunity of repeating and completing my experiments, and hope then to bring the question to a satisfactory close. As, however, some time may elapse before I can resume work, I wish to say now a few words in answer to Mr. Stearn's letter.

Before all, I wish to state clearly in what way the correctness of the opinion I profess with regard to the band-spectrum of nitrogen would be affected by an error introduced into my experiments. The unexpected result of an experiment of mine, together with a remark which Plucker makes in one of his papers, suggested to me the idea that the so-called band-spectrum of nitrogen might be that of the oxides of nitrogen. I was confirmed in this idea soon afterwards by a remark of Angström in his recent paper on double spectra (*Comptes Rendus*, August 17, 1871, but which was omitted in the English translation), by which he calls attention to the close resemblance of this band spectrum with the spectrum of metallic oxides. I have described in my paper the experiment just mentioned. A rather narrow tube showed, when exhausted, the lines of nitrogen; as soon as the air entered the bands appeared. The remark of Plucker alludes to the fact that a tube filled with oxides of nitrogen showed the bands with unusual brilliancy. In order to test the accuracy of this opinion I intended to make a crucial experiment by taking care to remove every trace of oxygen. I used for this purpose, at the suggestion of Dr. Balfour Stewart, small pieces of sodium heated in the vacuum tubes. The sodium was fused several times in succession in order to free it from impurities. When the nitrogen was thus treated it always showed a line spectrum, the lines of which seemed to coincide with those of the known line spectrum of nitrogen when measured with the instrument at my disposal. It seems now that I have been too hasty in assuming that this apparent coincidence was a real one. While passing through London a few weeks ago, Dr. Huggins was kind enough to allow me the use of his spectroscope in order to compare, under his supervision, the spectrum of my tubes with the real line spectrum of nitrogen. I then found that, although my tube shows a line which is very near the principal double line of nitrogen, the spectrum is not that of nitrogen. I am at present unable to say what is the origin of this spectrum; but I do not think that its formation can be brought forward as a proof that the band spectrum is not due to oxides of nitrogen. On the contrary, it rather shows that an impurity which has no effect on the spectrum of air, will have one when all the oxygen is removed, and that a change has therefore probably taken place in the conducting power of the gas which gives out the spectrum.

I do not quite see the real object of Mr. Stearn's letter. If he merely wishes to say that the proof brought forward by me is insufficient, and that the question must still remain an open one. I confess I have nothing to say against it. If he, however, wishes to convey the idea that nitrogen has really a double spectrum, I do not think his argument is a correct one.

I will not trespasss any longer upon your space, but I may, I think, fairly ask your readers to suspend their judgment until I have completed my experiments.

Heidelberg, May 30 Arthur Schuster

Ground Ivy

With respect to the question started in the number for June 12 of this journal as to the Ground Ivy, it may be said that in *Glechoma*, as also in *Origanum vulgare*, *Thymus serpyllum* and *vulgaris*, and *Mentha vulgaris*, specimens having flowers with small corolla and undeveloped anthers are very common, I think as common as specimens having flowers with large corolla and the two sexes developed. Also of *Mentha aquatica* and *Prunella vulgaris* specimens with smaller corolla and only pistils developed are found, but much more rarely than those of the other form.

I have attempted in my work to give an explanation of the origin of the second form of the above-mentioned Labiatæ, as follows:—

The species named are distinguished from our other Labiatæ by the coincidence of the following three peculiarities:—

1. By an abundance of honey, and in consequence of that by an abundance of insects visiting and cross-fertilising them.*

2. In the hermaphrodite flowers, by a stigma so far overtopping the anthers and developed so long after the anthers that self-fertilisation is impossible, or nearly so.

3. By a great variability in the size of the corolla in the hermaphrodite flowers of different specimens.

Now when the flowers on different stems of the same species differ in the size of their corolla, it is evident *a priori*, and ascertained by direct observation, that generally those with the largest corolla are the first seen and visited by insects flying near them, those with the smallest corolla the last. The latter, always the flowers last visited, are fertilised exclusively by the pollen of previously-visited flowers, consequently produce their pollen in vain; and since the non-production of useless organs is always an advantage to every organic being, varieties of the smallest

* For instance, I found *Thymus serpyllum* visited by 7 species of Apidæ, 3 species of *Sphegidæ*, 14 species of Diptera, and 6 species of Lepidoptera; *Glechoma* visited by 21 species of Apidæ, 8 species of Diptera, and 3 species of Lepidoptera.

flowered form must be favoured in the struggle for existence, when ceasing to develop their useless anthers. Thus of the smallest-flowered form, varieties with atrophied anthers of necessity remained at last the only survivors.

Lippstadt, June 17 H. MÜLLER

ALL the flowers of the ground ivy (*Nepeta Glechoma*) that I have this season examined, from this neighbourhood, have been of the stamenless form described by your correspondent "S. S. D." While spending a few days at Bath, I could find none but hermaphrodite flowers. At Hertford I found both forms, but a preponderance of hermaphrodites. These seem always more or less protandrous, and spontaneous self-pollenation is further prevented by the unequal lengths of the style and stamens.

Kilderry, Co. Donegal W. E. HART

Lotus corniculatus

MR. W. E. HART (NATURE, June 12) is quite right in correcting me on the subject of the fertilisation of *Lotus corniculatus*. It is the outer whorl of stamens, those opposite the calyx teeth, which continue to grow after the others, and which have their filaments dilated at the top so as to thrust the pollen out of the long sharp tube of the keel. I should scarcely have thought it necessary to acknowledge his courteous correction, if it were not for the following question and answer: How is it, then, that the pollen of the inner and shorter whorl of stamens, which discharge their pollen at the same time as the outer whorl, gets pushed out by the filaments of the outer whorl, since the anthers of the inner whorl lie below the summits of the filaments of the outer whorl? The answer is curious: In the early bud, before the anther cells begin to open, the inner whorl is obviously shorter than the outer whorl, so that the anthers of the former lie in a regular row entirely below the anthers of the latter, apparently for the convenience of close packing in the narrow closed flower. As the anther cells begin to open, which is just before the flower opens, the stamens of the inner whorl grow and approach very nearly in height to the stamens of the outer whorl; and as they shed their pollen from the summit of the anthers, their pollen comes out above the dilated tops of the filaments of the outer whorl, so that it can be pushed forwards by those filaments along with the pollen of their own anthers. The filaments of the inner whorl then wither and become comparatively short, while those of the outer whorl continue to grow, dilate, and stiffen, so as to do the work for all the pollen of both whorls. In the mature opened flower the difference between the two whorls becomes more marked than ever. If I am right, Mr. Hart's detection of my blunder leads to the notice of a curious instance of economy of space and of mechanism. T. H. FARRER

Abinger, Surrey, June 21

The Secchi and Respighi Methods

IN the number of NATURE for June 12, p. 136, I see that you notice the results obtained in the last eclipse with the use of the spectroscope for determining the first entrance of the moon or planet. There seems, however, to be some confusion in the report. You say that I propose Respighi's method for first contact, and my own for the last. This is not the case. I propose the common Respighi method as useful for obtaining a *first warning* of the entrance of the planet on the chromosphere. This is the only use I think it possible to make of it. But the real entrance must be obtained by my method, in which one sees the disc of the sun as with a common glass, and the line of the chromosphere tangent to it, can be seen broken at the instant of contact, as the ring of Venus is broken at its exit from the solar disc.

You say also (page 131, col. 1) that it is difficult to obtain a perfect adjustment on account of the inequality of the driving-clock. If you say so for the common spectroscopic method, I agree perfectly with you, because the edge of the disc cannot be seen; but with my method this difficulty does not exist. It is not more difficult to keep the sun's disc tangent to the chromospheric line, than to keep it tangent to a common wire; the clock can help, but it is not necessary to have it in perfect order; even with common handles one can obtain it. The reason is that the solar disc being perfectly visible, one is greatly helped by the edge of the sun itself, while in common methods the edge of the sun is not seen.

Rome, June 16 P. A. SECCHI

P.S.—More on this will be found in the *Memorie del. Soc. degli Spettroscopisti Ital.*

Gassendi and the Doctrine of Natural Selection

NO one having yet replied to the question in Mr. Monro's letter (see NATURE, vol. vii. p. 402), I venture to hope that you will give me space for a few remarks on Gassendi's physical philosophy, and more especially on that part of it germane to the subject discussed by Mr. Monro.

The apparent implication of the question referred to is, that anticipations of natural selection are to be found in Gassendi's writings. Allowing to the term its utmost latitude of meaning, this does not appear to me to be the case. In his historical sketch of the various views which poets and philosophers have held as to the origin of things, Gassendi gives the theory of Empedokles at some length, including the passage on the βουγενῆ ἀνδρόπρωρα which Mr. Monro quotes in his letter. But Gassendi has no word of approval for the theory; he classes it with other Greek cosmogonies, such as those of Anaximander, Pythagoras, &c., and with the Chinese and Hindu cosmogonies as "fabulares sententias philosophorum," not less fabulous indeed than the poetic fictions of Prometheus, Deukalion, and Kadmus. Here, too, as well as in other parts of his works, Gassendi blames philosophers for ascribing to the action of natural laws effects which he regards as direct results of the Divine power.

Before giving a brief summary of Gassendi's own views, I will premise that it is not easy to discover them with exactitude. His works are very voluminous, both the Lyons edition of 1658, and the Florence edition of 1728, occupying six bulky and closely printed folio volumes. Even the abridgment made by his disciple Bernier fills seven vols. 12mo. Ordinary histories of philosophy give for the most part a very meagre account of the French forerunner of Locke; and more comprehensive works, like those of Tennemann, Buhle, and De Gerando, deal with Gassendi as a psychologist and a moralist rather than as a physicist. Even Dr. Whewell, from whom, as the historian of the inductive sciences, more might have been expected, makes but a few cursory references to the philosopher who was one of the earliest and most pronounced followers of the Baconian method, and who, as De Gerando says, "enseignant les mêmes principes (as Bacon) les a surtout enseignés par son exemple." The work which, as far as I have seen, gives the most complete account of Gassendi as a physical philosopher is Schaller's "Geschichte der Naturphilosophie von Baco bis auf unsere Zeit." This writer takes Bacon, Hobbes, and Gassendi as the typical philosophers of the empirical or *a posteriori* school of natural philosophy. He devotes about one hundred pages to the exposition of Gassendi's physical doctrines, and concludes with an elaborate criticism of his atomic theory. The intrinsic obstacles to a precise appreciation of Gassendi's views are more serious. Not far removed from the age of scholasticism he exhibits, in a modified degree, two of the distinctive features of the schoolmen, their pedantic erudition, and their commentatorial spirit. The wealth of quotation with which his pages are burdened rather than adorned has laid him open to the charge "de laisser étouffer ses propres idées sous le poids des citations empruntées aux anciens." He better deserves the second than the first clause of Gibbon's epigrammatic eulogy: "Le meilleur philosophe des littérateurs, et le meilleur littérateur des philosophes." A work largely imbued with the commentatorial spirit, as the *Syntagma Philosophicum* is, is always more valuable as a history of philosophic opinion than as a source of new philosophic thought. Again Gassendi's bent of mind, coupled with the exigencies of his position as a Church dignitary, seems to me to have precluded his holding opinions of a very decided and novel character. True or not, the reason he is said to have given for adopting the atomism of Epicurus rather than the Cartesian theory of vortices is somewhat characteristic; "Chimæra for chimæra I cannot help feeling some partiality for that which is two thousand years older than the other."

In his views as to the origin of things, Gassendi is at once an atomist and a special creationist. One experiences a certain sense of incongruity in noticing the way in which, while following the Biblical narrative for the main outlines of his doctrine, he fills in the details from Atomism. In the beginning there was a chaos in which the Deity had intermingled in manifold confusion atoms, molecules, *corpusculæ insectiliæ*, or *minima naturalia* (a phrase borrowed from Lucretius) of every kind, celestial and terrestrial, organic and inorganic, animal and vegetal. Upon these atoms had been impressed peculiar motions and affinities. At the creation of the world, as the creative fiats in their turn went forth, the potential motions and affinities of each species of atom became kinetic, and by the concourse of

atoms, similarly endowed, the successive stages of creation were accomplished. There is so much resemblance between Gassendi's account of the appearance of the different animal forms, and the Miltonic narrative of the time when "the grassy sods now calved," that the question suggests itself whether the "Paradise Lost," which appeared in 1667, might not have been influenced by the *Syntagma Philosophicum*, its predecessor by some twenty years? From the side of Atomism Gassendi seeks to explain the Divine cessation from labour after the six stages of creation. Besides the atoms which, when endowed with kinetic energy, gave rise to the primordial plants and animals, there remained others in which their characteristic motions and affinities still continued potential, and which had been subject to distribution only. These account on the one hand for the seminal reproduction of plants and animals, and on the other for the phenomena of so-called spontaneous generation. On this view, as may be supposed, spontaneous generation presents few difficulties to Gassendi. He needs but the hypothesis of the endurance from the creation of the atoms special to any peculiar form of life. Then, when their potential motions and affinities become kinetic, they must of necessity issue in the forms of life which by their concourse they were destined to produce. Two points are worthy of notice in this connection—Gassendi's definition of spontaneous generation, and his list of animals produced spontaneously. Spontaneous generation is not generation "sine seminibus" (germs), but "sine parentibus." Amongst his "animalia sponte nascentia" are enumerated "mures, vermes, ranæ, muscæ, aliaque insecta."

In a theory such as this is there no evolution, no selection. The atoms themselves are unchangeable, and so are the specific characters of the aggregates which they build up. Plants and animals, as they now are, are but copies of the primitive forms, be they produced by gamogenesis or spontaneously. The natural conditions also by which floral and faunal habitats and distribution are regulated, Gassendi seems to regard as having been fixed once for all at the creation. Reading "Deus" for "Natura," Virgil's lines express Gassendi's views on this point—

> "Continuo has leges, æternaque fœdera certis
> Imposuit Natura locis."—(Geo i., vv. 60, 61.)

There is a sort of superficial resemblance between Gassendi's atoms and Mr. Spencer's "physiological units," but with capital points of difference. In both theories the molecules of each species of plant and animal have distinctive characteristics, and an inherent power of arranging themselves in the form of the organism to which they appertain. But while Gassendi's atoms are simple and indivisible, as one of their synonymes, *corpusculæ insectiliæ*, connotes, Mr. Spencer's physiological units are complex. While Gassendi's atoms are specific creations and endowed with unalterable properties, Mr. Spencer's physiological units are themselves the products of evolution, and are perpetually undergoing adaptation to equilibrate the action of forces internal and external.

I am inclined to suspect that Maupertuis may have, in the main, borrowed the atomic theory contained in the "Système de la Nature" from Gassendi. The materialism which led Maupertuis to make perception a fundamental property of his atoms is, however, all his own; at any rate it is not Gassendi's.

In Physics as in Ethics, the nearest affinity of the philosophy of Gassendi is to that of Epicurus. It is Epicurianism modernised, and modified so as not to clash, openly at least, with Christianity and with the dogmas of the current theology. By his want of originality he was led to base his philosophy on an already established system, and by his adoption of Bacon's method he was attracted to Epicurus, for that philosopher and his school were the sole ancient representatives of the new *a posteriori* philosophy. De Gerando thinks that an additional link between Gassendi and Epicurus existed in the similarity of their views on the physical doctrines of a vacuum and of atoms. But it seems at least as probable that the French philosopher adopted these conceptions from the Greek, as that he reached them by his own independent thought. While, however, he was essentially an Epicurean, Gassendi was careful not to commit himself to any doctrines which might cause his orthodoxy to be questioned; in fact, he more than once clearly expresses this determination.

"How far back can traces of the great theory of Darwin and Spencer be discovered?" As I showed in my letter on Maupertuis, in NATURE, vol. vii. p. 402, the doctrine is discoverable in that writer; but De Maillet, with whom Mr. Spencer begins his historical sketch, is a quarter of a century earlier than Maupertuis. My examination of Gassendi leads me to the conclusion that the doctrine of Natural Selection is not to be found in his works, and further that his views, as far as I understand them, effectually preclude his holding the theory under any form.

W. H. BREWER

P.S.—On looking back over what I have written, I find that I have omitted to point out the different attitudes of Gassendi towards the two distinct portions of his cosmological views. When he is borrowing from the Mosaic account of the creation, all his assertions are positive, for here we have "quod Fides et Sacræ Literæ docent." When, however, he is borrowing from Atomism his views take a hypothetical form, and are introduced by the phrase "nihil vetat supponere."

Grace's Road, Camberwell

Care of Monkeys for their Dead

As a supplement to the extract from James Forbes' "Oriental Memoirs," given by Dr. Gulliver in NATURE (vol. viii. page 103), the following incident, recorded by Capt. Johnson, deserves republication:—

"I was one of a party at Jeekarry, in the Bahar district; our tents were pitched in a large mango garden, and our horses were picqueted in the same garden at a little distance off. When we were at dinner, a Syce came to us complaining that some of the horses had broken loose in consequence of being frightened by monkeys (*i.e. Macacus Rhesus*) on the trees. . . As soon as dinner was over, I went out with my gun to drive them off, and I fired with small shot at one of them, which instantly ran down to the lowest branch of the tree, as if he were going to fly at me, stopped suddenly, and coolly put his paw to the part wounded, covered with blood, and held it out for me to see. I was so much hurt at the time that it has left an impression never to be effaced, and I have never since fired a gun at any of the tribe.

"Almost immediately on my return to the party, before I had fully described what had passed, a Syce came to inform us that the monkey was dead. We ordered the Syce to bring it to us, but by the time he returned, the other monkeys had carried the dead one off, and none of them could anywhere be seen."

G. J. R.

The Intellect of Porpoises

In Prof. Huxley's admirable criticism of "Mr. Darwin's Critics," * the following passage occurs:—"The brain of a porpoise is quite wonderful for its mass, and for the development of the cerebral convolutions. And yet, since we have ceased to credit the story of Arion, it is hard to believe that porpoises are much troubled with intellect."

I have no doubt that Prof. Huxley will agree with me in further concluding that "it is hard to believe" that the remarkably developed cerebral hemispheres of the porpoise with their deep and numerous convolutions perform no more exalted functions than the smooth pair of mere pimples that stand behind the olfactory ganglia of a cod-fish, and constitute the whole of his claim to a cerebrum proper.

The psychology of the porpoise (and also that of the dolphin and other cetaceans with similar brains) is thus a subject of primary interest to the student of cerebral physiology. As a contribution to the subject I offer the following facts:—

Many years ago I made the voyage from Constantinople to London in a small schooner laden with box-wood, &c. The passage was very slow, occupying fully two months, including the whole of August, and parts of July and September. We were often becalmed, with porpoises playing about the ship. The sailors assured me that no sharks were in the neighbourhood while the porpoises were near, and accepting this generalisation I frequently plunged overboard and swam towards the porpoises. They usually surrounded me in a nearly circular shoal or company, and directed towards their unusual visitor an amount of attention which I may venture to dignify with the title of curiosity. Their respiratory necessities precluded any long-continued scrutiny, but after dashing upwards for their customary snort, they commonly resumed their investigations, sometimes approaching uncomfortably near and then darting off to the circumference of the attendant circle. I am not able to describe the expression on the *features* of a porpoise, but my recollection of that of the eyes of my swimming companions is very different

* *Contemporary Review*, 1871. Reprinted in "Critiques and Addresses."

from what I have since seen on the large vacant orbs of aquarium cod-fishes, &c.

I have not yet seen the porpoises in the Brighton Aquarium, but suspect that if they contrive to "make themselves at home" there, a careful study of their habits will remove some of the difficulty which Prof. Huxley experiences in believing in their intelligence.

W. MATTIEU WILLIAMS

Instinct

A DIFFICULTY occurred to me on reading Mr. Lewes's interesting and instructive article on "Instinct" in NATURE of April 10—and as no satisfactory answer offers itself to me, I venture to trouble you with it.

Wherein lies the difference in kind between the actions performed instinctively by animals for the preservation of themselves or their young, and those actions performed by plants with the same result?

For instance; the Ivy Linaria grows on an old wall; its flowers and the flower-stalks stand out for the sun and insects to visit the little "snap-dragon." But no sooner does the corolla fall, than the peduncle begins to curve inwards to the wall, and usually contrives to tuck its seed-vessel well into the brickwork again. We cannot say of such an action that there is "no alternative open to it;" and even if we do, it does not explain it to call it "impulsive," and yet one is not prepared to accept it as an instance of instinct. I shall be grateful for any elucidation.

M.

Grus vipio

I OBSERVE that in your report of the meeting of the Zoological Society on the 6th ult., in your issue of the 15th, it is stated, with reference to *Grus vipio* (*seu leucauchen*), that "no example of this fine species, so far as was known, had previously been brought alive to Europe." Last autumn, when going over the Zoological Gardens at Amsterdam with the superintendent, Mr. Hegt, I saw there a splendid pair of these birds, which had been purchased for 140*l.*, and had bred the same spring, and reared successfully a fine young bird, about two-thirds grown when I saw it in September, destined, as I was informed by Mr. Hegt, for the Berlin Gardens. The collection of cranes at Amsterdam is exceedingly rich, far surpassing either London or Antwerp in this respect. It contained, when I saw it, fourteen out of the fifteen valid species of Grus, comprising, besides the above-mentioned, *G. vipio*, a splendid pair of *G. viridirostris*, a fine *G. leucogeranus*, *G. carunculatus*, *G. canadensis*, *G. Americana*, *G. torquata*, &c., the desideratum being *G. monacha*, of Japan.

W. A. FORBES

Culverlea, Winchester, June 2

ON THE SYNTHESIS OF MARSH-GAS AND FORMIC ACID, AND ON THE ELECTRIC DECOMPOSITION OF CARBONIC OXIDE *

IN connection with the investigation on the electric decomposition of carbonic-acid gas referred to in a previous communication to the Society, I was led to submit a mixture of hydrogen and carbonic-oxide gas to the action of electricity in the induction-tube, the mixed gases being circulated through the tube by means of an apparatus which I will not now describe. A contraction was soon observed to have taken place, which at the end of an hour amounted to 10 cub. centims. The rate of contraction steadily diminished, and during the fifth hour of the duration of the experiment amounted to only 2 cub. centims. The experiment was stopped, and the gas analyzed with the following results in two several analyses:—

	I.		II.
Carbonic oxide	61·65	Carbonic oxide	61·35
Hydrogen	32·16	Hydrogen	32·34
Marsh-gas	6·14	Marsh-gas	6·31
	100·00		100·00

A small quantity (about 2 per cent.) of nitrogen was also contained in the gas, together with a trace of oxygen, which have been omitted from the calculation.

The result of this reaction is expressed in the following equation:—

$$CO + 3H_2 = CH_4 + H_2O.$$

This fundamental experiment, which constitutes the basis of a new method of chemical synthesis, susceptible of the most varied applications, and of peculiar interest in reference to the explication of natural phenomena, was commenced by me on the 10th of January last at Oxford, in the laboratory of my friend and successor in the Chair of Chemistry, Prof. Odling; two analyses of the gas were completed, and the results attained in the course of a week from that date. In a similar experiment made with a mixture of hydrogen and carbonic-acid gas, a contraction also occurred, attended with the formation of water. The gas which resulted from the experiment was found to consist (after the absorption of carbonic acid) of hydrogen and carbonic oxide, together with a little marsh-gas. Traces of oxygen and nitrogen were also present. Minute drops, too, of an oily liquid appeared in the tube. This liquid, after the conclusion of the experiment, was dissolved in a small quantity of water. The solution was strongly acid and had a pungent taste. It reduced an alkaline solution of terchloride of gold and an ammoniacal solution of nitrate of silver. These reactions are the characteristic properties of formic acid, of which we may infer the synthesis to have been effected according to the equation

$$H_2 + CO_2 = H_2CO_2.$$

I may avail myself of the present opportunity to place on record the following important facts in reference to the action of electricity on carbonic-oxide gas.

When pure and dry carbonic oxide is circulated through the induction-tube, and there submitted to the action of electricity, a decomposition of the gas occurs, attended with a gradual and regular contraction, which, in the form assumed in my experiments, occurred at the regular rate of about 5 cub. centims. in an hour. Carbonic acid is formed, and simultaneously with its formation a solid deposit may be observed in the induction-tube. This deposit appears as a transparent film of a red-brown colour, lining the walls of the tube. It is perfectly soluble in water, which is strongly coloured by it. The solution has an intensely acid reaction.

The solid deposit in the tube, in the dry condition before it has been in contact with water, is an oxide of carbon. Samples, however, made in different experiments do not present precisely the same composition; but nevertheless they appear to belong to a certain limited number of forms which repeatedly occur, and may invariably be referred to the same general order or system. This system is, or appears to be, what I may term a homologous series of "oxycarbons," of which the unit of carbon with the weight 12 may be regarded as the first term, and of which the adjacent terms differ by an increment of carbonic oxide (CO) weighing 28, precisely as homologous series of hydrocarbons differ by the increment CH_2 with the weight 14. I have succeeded in identifying by analysis two at least of these substances, namely, the adjacent terms C_4O_3 and C_5O_4. From this point of view these peculiar bodies are members of a series of oxycarbons analogous in the oxycarbon system to the series of hydrocarbons of which the unit of carbon is the first and the unit of acetylene C_2H_2 is the second term, the oxycarbon C_4O_3 being represented in that series by the hydrocarbon crotonylene C_4H_6, and the oxycarbon C_5O_4 by the hydrocarbon valerylene C_5H_8.

THE LAW OF STORMS DEVELOPED *

III.

FROM the Cape of Good Hope, in a straight line toward the projecting eastern coasts of Brazil, mariners have found a peculiar streak of south-easterly winds.

* Continued from p. 148.

Between the island of Tristan da Cunha and the Cape, and northward and westward to the island of Fernando Noronha this streak of powerful winds, with which nothing in the trade-wind region of the North Atlantic can compare, has its atmospheric current as sharply marked as the dark blue and rapid current of the Gulf Stream in the Narrows of Bemini. It is, doubtless, the region or band of most intensely acting south-east trades, and is probably due to the peculiar configuration of the shores of the South Atlantic, and to the wall of the South American Andes. It is a well-known fact that the volcanic cone of Teneriffe, which lies in the zone of north-east trades, intercepts the wind and gives it a lateral deflection; so that, while the trades are blowing strongly on the north-east side of the island, on the opposite side there is a distinctly-marked and carefully-measured calm shadow. Now, the chain of the Andes endeavours to exert on the south-eastern trades just such an influence as is exerted by the Canary Islands on the north-east trades. This influence, in the former case, suffices to throw off from the Continent of South America a large body of the south-east trades, and to deflect it to the eastward, giving it the character of a south-south-west wind, and, at the same time, by forcing a greater or more concentrated body of air into the regions north-east of Brazil, imparting an increased velocity and violence to the air-current. It is, therefore, in the air current that the homeward-bound vessel from the Cape of Good Hope aims to steer, because she is sure of being wafted happily and swiftly to her destination.

It has long been demonstrated by meteorologic observations, taken both at sea and on land, that there is very much *less* atmosphere in the Southern Hemisphere than in the northern, and for a long time physicists were at a loss to account for the difference. It has been, however, very satisfactorily explained by the eminent American mathematician, Ferrel, in his work on the "Motions of Fluids and Solids, relative to the Earth's Surface," where he proves at length, and states in detail (p. 39): "As there is much more land, with higher mountain ranges, in the Northern Hemisphere than in the southern, the resistances are greater, and consequently the eastward motion of the air, upon which the deflecting force depends, is much less; and the consequence is, that the more rapid motions of the Southern Hemisphere cause a greater depression there, and a *greater part of the atmosphere to be thrown into the Northern Hemisphere*." It is, doubtless, to this tendency of the Southern Hemisphere to throw off much of its atmosphere north of the equator that we may attribute in part the superior force and power of the south-east trades, and their well-known ability to battle with the north-east trades, and drive them from their own territory, at least all summer, and even in winter, as far back across the line as 3° or 4° north latitude. Mr. Ferrel, speaking of the principle just enunciated, well says: "This also accounts for the mean position of the equatorial calm-belt being, in general, a little north of the equator. But, in the Pacific Ocean, where there is nearly as much water north of the equator as south (and the resistances are usually equal), its position nearly coincides with the equator." In other words, just as a bucket full of water revolving on a perpendicular axis would show a depression in the centre, and the fluid be thrown from all sides of its rim, the Southern Hemisphere throws its water and its atmosphere into the Northern hemisphere, all along the equator.

It is, therefore, a mathematical and mechanical certainty that there is an invasion of the north-east trade-wind belt from the south-east trades, and observation powerfully bears out the deduction of the mathematician. Ansted states in his cautiously-written "Physical Geography:"—"The southern trade-wind region is much larger than the northern in the Atlantic Ocean. In this sea, the south-east trades are fresher, and blow stronger, than the others, and often reach to the 10th or 15th parallel of north latitude; whereas the northern trade-wind seldom gets south of the equator, and usually ranges from 9° to 29° north latitude" (p. 253). It is not difficult to see how easily it happens that a very small atmospheric eddy found in the tropical Atlantic by the conflictory north-east and overleaping south-east trade-winds may soon become a hurricane of wide extent and of tremendous energy. All that is necessary, as we have before seen, is that an initial impulse of gyration be given to a body of air. The moment that this takes place by mechanical influence, and centrifugal force creates the smallest eddy or vortex, the surrounding air, already highly charged with moisture, begins the process of convergence and ascensional motion, followed rapidly by condensation aloft.

The storm-cylinder—the nucleus of the hurricane—originally very small, is instantly enlarged and expanded by the evolution of latent heat stored away in the vesicles of aqueous vapour. For some hours, as all observations show to be actually the case, the incipient cyclone scarcely moves, while gathering in its energies and laying tributes upon all contiguous regions. The process continues with momentarily increasing intensity, and, before the sun has made his daily circuit, the meteor is formed.

If it be asked along what parallels of latitude in our hemisphere this formation takes place, the intelligent reader will at once answer, Near the terrestrial circle of trade-wind interference. This, we have already seen, is in summer, from the 10th to the 12th parallels of north latitude.

This slender zone of debatable ground is the battle-field of the two opposing bands of the trades. There is really no need of observations to tell us as much. But millions of observations attest the fact. Every seaman knows it. Every meteorological writer tells the same story. You have only to examine physical charts from the time of Columbus and Magellan to this, to see the absolute unanimity of testimony, and to discover that the hypothesis now advanced, and the known facts of the case, are in perfect and minute accord.

If it be asked whether the origin and interest of the West-Indian gales is *solely* due to mechanical interference, the proper reply, it would appear, should be in the negative. As the south-east trade-wind comes laden with the vapour of the southern or water hemisphere, which Dové well called "the boiler" of the globe, it is met by the cold north-east trade from the northern, or land hemisphere. There must be a great difference in their temperatures, and consequently extensive condensation, which, by the reasoning of Mr. Clement Ley, would, of itself, explain the formation of the storm. That condensation greatly assists in producing or intensifying it, cannot be doubted. In the high latitudes, where the polar air-current is sometimes forced by barometric pressure into the southerly or equatorial current moving over the warm waters of the ocean, and thus heavily vapour-laden, the consequence is illustrated by such terrific and sudden tempests as that of the *Royal Charter*, distinctly proved by Admiral Fitzroy to have been generated between the opposite polar and equatorial currents off the coast of Wales.

But that the origin of great depression-systems is solely due to condensation can hardly be sustained, and seems entirely overthrown if we regard the single fact that, on the great equatorial belt—the belt of perennial precipitation—no hurricane or typhoon has ever been experienced by the mariner. It has long been, and is now, the almost universally accepted theory of meteorologists, that the reason no cyclones have ever been known to occur on the equator is, that there the earth's rotation exerts a deflecting influence on the winds, amounting to zero, and hence the formation of a whirl is impossible. This view is not satisfactory, because the nucleus of a depression

once formed on the equator, there would be intro-moving masses of air proportioned in violence to the amount of the depression and the steepness of the barometric gradient down which they rush to reach the point of

WEATHER-CHART OF GREAT BRITAIN, BEFORE "ROYAL CHARTER" STORM.
Full-feathered arrows show Polar current; half-feathered arrows show Equatorial current; dark-coloured surface not reported by vessels or land-observers.

lowest barometer. The true reason that no great cyclone has ever been formed nearer the equator than the third parallels of latitude appears to be, that the equatorial belt is a belt of *non-interference.*

ON THE ORIGIN AND METAMORPHOSES OF INSECTS *

VII.

On the Origin of Insects

"PERSONNE," says Carl Vogt, "en Europe au moins, n'ose plus soutenir la Création indépendante et de toutes pièces des espèces," and though this statement is perhaps not strictly correct, still it is no doubt true, that the Doctrine of Evolution, in some form or

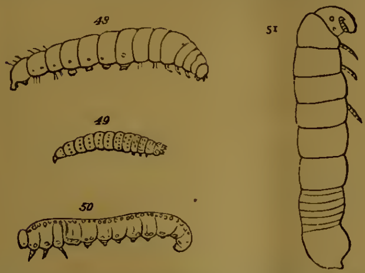

Fig. 48, Larva of Moth (*Agrotis suffusa*), after Packard. 49, Larva of Beetle (*Haltica*), after Westwood. 50, Larva of Sawfly (*Cimbex*), Brischke and Zaddach. Beob. ub d. artm. der Blall—Holzwespen, Fig. 8. 51, Larva of Julus. Newport, Philos. Transactions, 1841.

other, is accepted by most, if not by all, the greatest naturalists of Europe. Yet it is surprising how much, in spite of all that has been written, Mr. Darwin's views are

Fig. 52, Agrotis suffusa (after Packard). 53, Haltica (after Westwood).

still misunderstood. Thus Browning, in one of his recent poems, says:—

> "That mass man sprang from was a jelly lump
> Once on a time; he kept an after course
> Through fish and insect, reptile, bird, and beast,
> Till he attained to be an ape at last,
> Or last but one." †

Fig. 54, Cimbex, Brischke and Zaddach, l.c. T. 2, Fig. 9.

Yet this is a theory which Mr. Darwin would entirely repudiate; which is utterly inconsistent with his views. Whether fish and insect, reptile, bird, and beast, are derived from one original stock or not, they are certainly not links in one sequence. I do not, however, propose to discuss the question of Natural Selection, but I may observe that it is one thing to acknowledge that in Natural Selection, or the survival of the fittest, Mr. Darwin has called attention to a *vera causa*, has pointed

Fig. 55, Julus (after Gervais).

out the true explanation of certain phenomena; but it is quite another thing to maintain, that all animals are descended from one primordial source.

For my own part, I am satisfied that Natural Selection is a true cause, and that whatever may be the final result of our present inquiries—whether animated nature is derived from one ancestral source, or from many—the

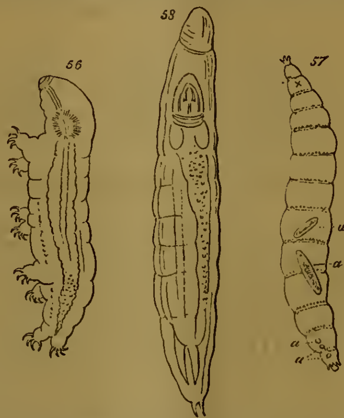

Fig. 56, Tardigrade (after Dujardin). 57, Larva of Cecidomyia (after Packard). 58, Lindia tomlosa (after Dujardin).

publication of the Origin of Species will not the less have constituted an epoch in the History of Biology. But, how far the present condition of living beings is due to that cause; how far, on the other hand, the action of Natural Selection has been modified and checked by other natural laws—by the unalterability of types, by atavism, &c.; how many types of life originally came into

Fig. 59, Prorhynchus stagnalis.

being; and whether they arose simultaneously or successively,—these and many other similar questions remain unsolved, even if we admit the theory of Natural Selection. All this has indeed been clearly pointed out by Mr. Darwin himself, and would not need repetition but for the careless criticism by which in too many cases the true question has been obscured. Without, however, discussing the argument for and against Mr. Darwin's conclusions, we so often meet with travesties of it like that which I have just quoted, that it may be worth while to consider the stages through which some group, say for instance

* Continued from p. 140.
† Prince Hohenstiel Schwangau, p. 68.

that of insects, have probably come to be what they are, assuming them to have developed under natural laws from simpler organisms. The question is one of great difficulty. It is hardly necessary to say that insects cannot have passed through all the lower forms of animal life, and the true line of their development would not at present be agreed upon by all naturalists. In this question embryology and development are perhaps our best guides. The various groups of Crustacea, for instance, greatly as they differ in their mature condition, are for the most part very similar when they quit the egg. Haeckel, in his "Naturliche Schopfungsgeschichte," gives a diagram which illustrates this very clearly.

In the case of insects, the gradual course of evolution through which the present condition of the group has been probably arrived at, has been discussed by Mr. Darwin, by Fritz Müller, Haeckel, Brauer, myself and others. At first sight the differences are indeed great between the various groups of insects. The stag beetle, the dragon fly, the moth, the bee, the ant, the gnat, the grasshopper—these and other less familiar types seem at first to have little indeed in common. They differ in size,

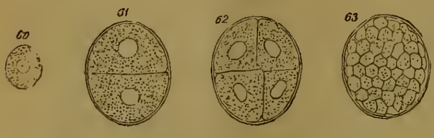

FIG. 60, Egg of Tardigrade, Kaufmann, Zeit f. Wiss Zool. 1851. Pl. 1 61, Egg of Tardigrade after the yolk has subdivided. 62, Egg of Tardigrade in the next stage. 63, Egg of Tardigrade more advanced.

in form, in colour, in habits, and modes of life. Yet the researches of entomologists, following the clue supplied by the illustrious Savigny, have shown, not only that while differing greatly in details, they are constructed on one common plan; but also that other groups, as for instance, Crustacea (Lobsters, Crabs, &c.) and Arachnida (Spiders and Mites), can be shown to be fundamentally similar. In Pl. 4 I have figured the larvæ of an Ephemera (Fig. 1), of a Meloe (Fig. 2), of a Dragon Fly (Fig. 3), of a Sitaris (Fig. 4), of a Campodea (Fig. 5), of a Dyticus (Fig. 6), of a Termite (Fig. 7), of a Stylops (Fig. 8), and of a Thrips (Fig. 9). All these larvæ possess many characters in common. The mature forms are represented in the corresponding figures of Plate 3, and it will at once be seen how considerably they differ from one another. The same fact is also illustrated in Figs. 48—55, where Figs. 48—51 represent the larval states of the mature forms represented in Figs. 52—55. Fig. 48 is the larva of a moth, *Agrotis suffusa* (Fig. 52); Fig. 49 of a beetle, *Haltica* (Fig. 53); Fig. 50 of a Saw Fly, *Cimbex* (Fig. 54); and Fig. 51 of a Centipede, *Julus* (Fig. 55).

Thus then, although it can be demonstrated that perfect insects, however much they differ in appearance, are yet reducible to one type, the fact becomes much more evident if we compare the larvæ. M. Brauer* and I † have pointed out that two types of larvæ, which Packard has proposed to call the Eruciform and Leptiform, run through the principal groups of insects. This is obviously a fact of great importance: as all individual Meloës are derived from a form resembling Plate 2, Fig. 2, it is surely no rash hypothesis to suggest that the genus itself may be so.

Firstly, however, let me say a word as to the general Insect type. It may shortly be described as consisting of animals, possessing a head, with mouth-parts, eyes, and antennæ; a thorax made up of three segments, each with a pair of legs; and a many-segmented abdomen with anal appendages. Into the internal anatomy I will not now enter. It will be seen that Plate 4, Fig. 4, representing the larva of a small beetle named Sitaris, answers very well to this description. Many other Beetles are developed from larvæ closely resembling those of Meloë (Plate 4, Fig. 2), and Sitaris (Plate 4, Fig. 4); in fact—except those species the larvæ of which, as, for instance of the Weevils (Plate 2, Fig. 6), are internal feeders, and do not require legs—we may say that the Coleoptera generally are derived from larvæ of this type.

I will now pass to a second order, the Neuroptera. Plate 4, Fig. 1, represents the larva of Chloëon, a species the metamorphoses of which I described some years ago in the Linnean Transactions,* and it is obvious that in essential points it closely resembles the form which I have just described.

The Orthoptera, again, the order to which Grasshoppers, Crickets, Locusts, &c. belong, commence life in a similar condition, and the same may also be said of the Trichoptera.

From the difference in external form, and especially the large comparative size of the abdomen, the larvæ of Lepidoptera (Fig. 48), and of certain Hymenoptera, for instance, of Sirex (Fig. 14) and Tenthredo, the Saw Flies (Fig. 50), have generally been classed with the maggots of Flies, Bees, Weevils, &c., rather than with the more active form of larva just adverted to. This seems to me, as I have already pointed out,† to be a mistake. If we look, for instance, at the larva of Tenthredo we see the three thoracic segments well marked, and the three pairs of legs. The abdominal prolegs, indeed, give the larvæ a very different appearance to those of the preceding type, but in some respects remove them still further from the apod, vermiform, larvæ. The larvæ of other species belonging to this group, for instance of Lyda, have no abdominal prolegs, and well developed though short antennæ. The caterpillar type differs then in its general appearance owing to its greater clumsiness, but still essentially agrees with that already described.

No Dipterous larva, so far as I know, belongs truly to this type; in fact, the early stages of the pupa in the Diptera seem in some respects to correspond to the larvæ of other Insect orders. The Development of the Diptera is, however, as Weissman ‡ has shown, very abnormal in other respects.

Thus then we find in many of the principal groups of insects that, greatly as they differ from one another in their mature condition, when they leave the egg they consist of a head; a three-segmented thorax, with three pairs of legs; and a many-jointed abdomen, often with anal appendages. Now is there any mature animal which answers to this description? We need not have been surprised if this type, through which it would appear that insects must have passed so many ages since (for winged Neuroptera have been found in the carboniferous strata) had long ago become extinct. Yet it is not so. The interesting genus Campodea (Pl. 3, Fig 5) still lives; it inhabits damp earth, and closely resembles the larva of Chloëon (Pl. 2, Fig. 1), constituting, indeed, a type which, as shown in Pl. 4, occurs in many orders of insects. It is true that the mouth parts of Campodea do not resemble either the strongly mandibulate form which prevails among the larvæ of Coleoptera, Orthoptera, Neuroptera, Hymenoptera, and Lepidoptera; or the suctorial type of the Homoptera and Heteroptera. It is, however, not the less interesting or significant on that account, since, as I have elsewhere endeavoured to point out, its mouth parts are intermediate § between the mandibulate and haustellate types; a fact which seems to me highly significant.

It seems to me, then, that there are good grounds for

* Wien. Zool. Bot. Gessels, 1869.
† Linnean Transactions, 1863.

* Linnean Transactions, 1866, vol. xxv.
† Linnean Transactions, vol. xxiv. p 65.

§ Linnæan Journal, v. xi.

considering that the various types of insects are descended from ancestors more or less resembling the genus Campodea, with a body divided into head, thorax, and abdomen; the head provided with mouth-parts, eyes, and one pair of antennæ, the thorax with three pairs of legs, and the abdomen, in all probability, with caudal appendages.

If these views are correct, the genus Campodea must be regarded as a form of remarkable interest, since it is the living representative of a primæval type from which not only the Collembola and Thysanura, but the other great orders of insects have derived their origin.

This ancient type may possibly have been derived from a less highly developed one, resembling the modern Tardigrades, a (Fig. 56) smaller and much less highly organised being than Campodea, which has been successively placed among the Acari and the Rotatora. It possesses two eyes, three anterior pairs of legs, and one at the posterior end of the body, giving it a curious resemblance to some Lepidopterous larvæ.

These legs, however, as it will be seen, are reduced to mere projections. But for them, the Tardigrada would closely resemble the vermiform larva so common among insects. Among the Coleoptera, for instance, the vermiform type occurs in the weevils; among Hymenoptera in the Bees and Ants; among Diptera it is general. Among Tricoptera the larva early acquires the three pairs of legs, but as Zaddach has shown,* there is a stage, though it is quickly passed through, in which the divisions of the body are indicated, but no trace of legs is yet present. Indeed, there appear to be reasons for considering that while among Crustacea the appendages appear before the segments, in Insects the segments precede the appendages, although this stage of development is very transitory, and apparently, in some cases, altogether suppressed. I say "apparently," because I am not yet satisfied that it will not eventually be found to occur in all cases. Zaddach, in his careful observations of the embryology of Phryganea, only once found a specimen in this stage, which also, according to the researches of Huxley, † seems to be little more than indicated in Aphis. It is therefore possible that in other cases, when no such stage has been observed, it is not really absent, but, from its transitoriness, has hitherto escaped attention.

Fritz Muller has expressed the opinion ‡ that this vermiform type is of comparatively recent origin; he says, "the ancient insects approached more nearly to the existing Orthoptera, and perhaps to the wingless Blattidæ, than to any other order, and the complete metamorphosis of the Beetles, Lepidotera, &c. is of later origin." "There were," he adds, "perfect insects before larvæ and pupæ." This opinion has been adopted by Mr. Packard § in his "Embryological Studies on Hexapodous Insects."

M. Brauer || also considers that the vermiform larva is a more recent type than the Hexapod form, and is to be regarded not as a developmental form, but as an adaptational modification of the earlier active hexapod type. In proof of this he quotes the case of Sitaris.

Considering, however, the peculiar habits of this genus, to which I have already referred, and that the vermiform type is altogether lower in organisation and less differentiated than the Campodea form, I cannot but regard this case as exceptional; as one in which the development has been, so to say, "falsified" by the struggle for existence, to use an expression of Fritz Müller's, and which therefore does not truly indicate the successive stages of evolution. On the contrary, the facts seem to me to point to the conclusion that, though the grublike larvæ of Coleoptera, and some other insects, owe their present form mainly to the influence of external circumstances, and partially also to atavism, still the Campodea type is itself derived from earlier vermiform ancestors. Nicolas Wagner has shown in the case of a small gnat, allied to Cecidomyia, that even now, in some instances, the vermiform larvæ retain the power of reproduction. Such a larva (as, for instance, Fig. 57) very closely resembles some of the Rotatoria, such, for instance, as Albertia or Notommata; these differ generally in possessing vibratile cilia. There is, however, one genus—Lindia (Fig. 58)—in which these ciliæ are altogether absent, and which, though resembling Macrobiotus in many respects, differs from that genus in being entirely destitute of legs. I have never met with it myself, but it is described by Dujardin, who found it in a ditch near Paris, as oblong, vermiform, divided into rings, and terminating posteriorly in two short conical appendages. The jaws are not unlike those of the larvæ of Flies, and indeed many naturalists meeting with such a creature would, I am sure, regard it as a small Dipterous larva; yet Dujardin figures a specimen containing an egg, and seems to have no doubt that it is a mature form.*

AMERICAN SCIENTIFIC EXPEDITIONS †

THE present year will be pre-eminently characterised in the history of the United States by the number of scientific expeditions, thoroughly equipped in every respect, and fitted out for exploration in various regions of the great West; and although most of them have been already referred to in our columns, it may be well to recapitulate them in geographical order. The most northerly is the International Northern Boundary Commission, which is intended to survey the line of the forty-ninth parallel, from the Lake of the Woods to the crest of the Rocky Mountains. The survey of the eastern section of the northern boundary of the United States was completed many years ago by Colonel J. D. Graham and others, and that of the western section, from the Pacific coast to the Rocky Mountains, was brought to a close in 1860. The middle section, as was the western, is in charge of Archibald Campbell, Esq., of Washington, as commissioner, with Major Twining as chief engineer officer on the part of the United States. Dr. Elliott Coues, of the army, the well-known naturalist, accompanies the expedition in that capacity, and the work will be done in connection with a large party, equally well equipped, detailed by the British Government.

The labour of this Commission was begun in 1872, consisting in the examination of the line from the Lake of Woods to Pembina, this village being the starting-point for the present year.

The next expedition is that along the line of the Northern Pacific Railway, and will consist of a body of about 2,000 troops, under the immediate command of Colonel D. N. Stanley. This will concentrate at Fort Abraham Lincoln, on the Missouri, now representing the western terminus of the Northern Pacific Railway, and its route will be westward toward and across the Yellow Stone River. This large force is intended to keep the Indians in check, and prevent any interferences on their part with the location and construction parties of the railway. In view of the fact that this expedition passes through a rich but little-known country, abounding in objects of natural history and zoology, the president of the National Academy of Sciences memorialised the Secretary of War in reference to the appointment of a

† Communicated by the Scientific Editor of *Harper's Weekly*.

corps of scientific men to accompany it; and this communication being favourably received, a number of gentlemen were duly commissioned. Some of these, however, subsequently found themselves unable to carry out their intention; but finally an organisation was completed, with Mr. J. A. Allen, of Cambridge, as zoologist; Dr. Lionel R. Nettre, of New York, as mineralogist and geologist; Mr. William Pywell, of Washington, as photograoher; Mr. Edward Konopicky, of Cambridge, as zoological and landscape artist; and Mr. C. W. Bennett as general assistant. These gentlemen have been commended especially to the kind attentions of General Sheridan and Colonel Stanley, and will receive every facility possible for carrying on their work.

The next expedition is that of Prof. F. V. Hayden, who continues the work upon which he has been engaged for so many years. His starting-point is Denver, and the region to be explored lies south of the fortieth parallel of latitude, and extending from Green River on the west to the eastern base of the Rocky Mountains. He expects to occupy several successive years in proceeding toward the Mexican boundary. The expedition has been divided into several parties, each with its commander. The general topographical and surveying work is under the direction of Mr. James T. Gardner, so well known in connection with Mr. Clarence King's explorations. Some of the specialists accompanying the expedition are Dr. F. M. Endlich and Mr. Marvin as geologists, and Mr. J. H. Batty as zoologist.

The next survey in the geographical order of arrangement is that of Lieutenant George M. Wheeler, in continuation of the labours of several preceding years. This expedition will be divided into four main field parties, one of which will be again subdivided, and includes four astronomical and triangulation parties. Party No. 1, under charge of Lieutenant Wheeler himself, will operate in portions of New Mexico and Arizona, and will be accompanied by Mr. G. K. Gilbert as chief geologist, and Dr. Oscar Loew as assistant geologist. Party No. 2, under Lieutenant Hoxie, will be accompanied by Mr. E. E. Howell as geologist, and Mr. H. W. Henshaw as naturalist. This party will move from Salt Lake to Camp Wingate, passing through portions of New Mexico and Arizona. The third party, under Lieutenant William L. Marshall, with Prof. J. J. Stevenson as geologist and mineralogist, and Dr. J. L. Rothrock as medical officer and naturalist, will move south-west from Denver through to Wingate, and explore also a portion of New Mexico and Arizona.

The fourth, or triangulation party, will start from Santa Fé, and carry a system of triangulation west to the meridian of Fort Wingate, and thence south to the Mexican border. The first astronomical party will be stationed at Salt Lake, with Mr. J. H. Clarke as observer; the second will be on the Denver and Santa Fé line, Dr. F. Kampf, observer; the third will be on the Union Pacific and the Central Pacific Railroad lines, with William W. Maryatt as observer; and the fourth party at Ogden, with Prof. H. B. Herr as observer. Here an observatory will be constructed for receiving signals from communicating stations, with a view of establishing differences of longitude.

The expedition of Major J. W. Powell on the Colorado River, in Utah, comes next in order, this gentleman being now occupied in finishing his work and preparing his report in compliance with the Act of Congress. Major Powell had been several years in this region, and has already constructed a map of wonderful interest and great accuracy. In connection with his work he has made a very large ethnological collection relating to the Piute Indians.

The explorations of Mr. Clarence King, who has been engaged for several years in the survey of the line of the fortieth parallel, will, it is understood, be completed during the present season by reviewing some portions of the route already traversed.

The engineer expedition under Captain Jones will also proceed from Cheyenne along the Wind River Mountains to some point on the Upper Missouri, and will be accompanied by Dr. Parry, the well-known botanist. It is also understood that a large Government party will start from Fort Ellis and proceed eastward, and form part of the Yellowstone expedition already referred to.

The exploration of Alaska will also be prosecuted in behalf of the Coast Survey by Mr. William H. Dall, who has already proceeded to the Aleutian Islands, with a view of preparing a proper chart of the same, and especially of selecting a suitable landing-place for the proposed Pacific Ocean cable. The labours of Mr. Henry W. Elliott and Captain Bryant in the islands of St. Paul and St. George, in Behring Sea, will, it is hoped, be as productive as in 1872.

Nearly all the parties referred to, while, of course, prepared for prosecuting the topographical, geographical, and astronomical service, are accompanied by competent geologists, botanists, and zoologists, and there is reason to believe that the amount of material which will be transmitted by them to the National Museum will exceed in magnitude and value that of any previous year since its establishment in 1857.

NOTES

At a meeting of the Geographical Society on Monday evening, Sir Bartle Frere, who was in the chair, intimated that the Queen had been graciously pleased to grant a pension of 300*l.* a year to Dr. Livingstone. We are glad to see that the daily press is becoming alive to the scandal of putting off with such a paltry gift a man who has spent his life in the disinterested service of his country and of humanity: he has surely *earned* something more handsome. Sir Bartle Frere read a letter from Dr. Kirk, which stated that the East Coast Expedition was getting on well, and that its members were in good health. Dr. Dillon and Lieutenant Cameron had succeeded in traversing the wet country, and were now engaged in collecting porters on the inland side of the river. Lieutenant Murphy and Mr. Moffat were understood to be following. His arrival had done much for the assistance of the expedition. No further news had of late been received of the expedition, a circumstance regarded by Dr. Kirk in a favourable sense. A letter from Lieutenant Grandy, from the Western Expedition, was then read. In this communication the writer, in giving an account of the progress of the expedition, stated that the men were all well, and that the climate was deliciously cool.

There will be an Election to Five Scholarships at Jesus College, Oxford, on Tuesday, October 14. The annual value of the Scholarships is 80*l.*, and they are tenable to the close of the twentieth term from the Scholar's matriculation. Candidates must not on the day of election be full twenty-four years old. One of these Scholarships is an Open Scholarship. It will be given according to proficiency in Physical Science, combined with the Classical attainments required by the University. The Examination for this will commence on Tuesday, October 7, and it will be held at Magdalen College in company with that for a Magdalen Demyship and a Merton Post-Mastership. Papers will be set in Chemistry, Physics, and Biology; and an opportunity will be given of showing a knowledge of practical work in Chemistry and Biology. Candidates for this Scholarship, if not otherwise admitted to the Examination, are requested to call on the Principal of Jesus College, on Monday, Oct. 6; and if so admitted, to call upon him on any day in the same week, and to bring with them certificates of age and of past good conduct.

THERE will be an election to a Fellowship in Natural Science at Magdalen College, Oxford, in October next, the holder of which will not be required to take Holy Orders. The examination will be held in common with Merton College, preference being given to proficiency in Biology, the College reserving to themselves the power of taking candidates in any other branch of Natural Science if it shall seem expedient to do so. Candidates must have passed all the examinations required by the University of Oxford or University of Cambridge for the degree of Bachelor of Arts, and must not be in possession of any Ecclesiastical Benefice, or of any Property, Government Pension, or office tenable for life, or during good behaviour (not being an Academical office within the University of Oxford), the clear annual value of which shall exceed 230*l*. They must also produce testimonials of their fitness to become Fellows of the College as a place of religion, learning, and education, and these must be sent to the President on or before Monday, Sept. 29. Candidates are required to call on the President on Monday, Oct. 6, between the hours of 3 and 5, or 8 and 9 P.M. The examination will commence the following day.

DR. JAMES BOTTOMLEY, B.A., D.Sc., F.C.S., has been appointed to the Science Mastership of the Taunton College School. The liberality of two or three munificent friends has enabled the headmaster to place the science teaching on a new and enlarged footing. Science has been taught in the school since 1865 with imperfect instruments, accommodation, and teaching power, yet with sufficient thoroughness to pass many pupils in the London Matriculations and in the scientific portion of the Oxford Local Examinations. The apparatus will now be largely increased, a temporary but efficient laboratory is about to be erected, and a science master of the highest reputation has been secured.

THE fine specimen of the Octopus brought to the Brighton Aquarium from the French Coast in April last and suspected at the time by Mr. Saville Kent to be a female, has just verified this anticipation by depositing numerous eggs. The position selected by the creature for their lodgment is most opportune, the several clusters being attached to the rockwork, close to one another, within a few inches of the front glass of its tank; thus affording every facility for their observation to the general public, and enabling the officers on the Naturalist's Staff to watch their progress towards maturity from day to day. The eggs were deposited on Thursday last, the 19th inst., since which time the parent has vigilantly guarded them, usually encircling and partly concealing the whole within a coil of one or more of her snake-like arms, and vigorously repelling the near approach of any of her comrades in the same tank. Like those of the Argonaut or Paper Nautilus, the eggs of the Octopus are of small size compared with the ova of other Cephalopoda, the individuals being no more than one-eighth of an inch in length, of oval form, and are crowded round a central flexible stalk two or three inches long. A dozen or more of these compound clusters, each including over a hundred eggs, represent the number already deposited by the female Octopus in the Brighton tanks. The mate of the interesting parent is a fine fellow brought from the Cornish Coast last February. On the arrival of his fair companion he immediately vacated his oyster grotto in her favour and for many subsequent days lavished upon her the most assiduous attention.

MR. LIVINGSTONE STONE, the Assistant Commissioner on the part of the United States, has been engaged for some time past in collecting fresh-water fishes of various species to be transported to California, for the purpose of introducing them into the rivers and ponds of that State. For this purpose he had sent to him a car of the Central Pacific Railway, which he has had fitted up properly for this object. At one end of the car is a plank pond, lined with zinc and holding four tons of water, over which are berths for Mr. Stone and his assistants. The rest of the car is occupied with smaller tanks, and a reserve of sea and fresh water, household and commissary supplies, &c. Among the species that Mr. Stone carries with him, in the form of partly hatched eggs or young, are shad, cat-fish, yellow perch, wall-eyed or glass-eyed perch, eels, lobsters, and the like; and there is every reason to believe he will succeed in transferring his freight without material loss. If he accomplishes his object of placing these fish in the California waters, there is every reason to expect them to constitute before many years an important addition to the food resources of the State.

MR. BENTHAM'S Anniversary Address to the Linnean Society, just printed at the request of the Fellows, deals chiefly with the progress of physiological botany during the past year. He refers especially to Strasburger's investigations of the floral structure of Coniferæ and Gnetaceæ, and to the genealogical theory by which that botanist makes the Conifers the parent race from which the Gnetaceæ have directly descended, these again having engendered the higher Dicotyledons. This theory Mr. Bentham considers to rest on very slender grounds, preferring the hypothesis that the Gnetaceæ have remained the least modified from the common stock, the Coniferæ having undergone a greater progressive change in one direction, the total separation of the sexes, the Dicotyledons a greater advance in another direction, the increasing complexity of the floral development. Haeckel's conjectural pedigree of the Calcisponges is also criticised.

THE "session extraordinaire" of the Botanical Society of France will be held this year at Brussels under the auspices of the Royal Botanical Society of Belgium. The session will commence by a meeting at the Botanic Gardens, Brussels, on July 9, at 9 A.M. Excursions will be made to the botanical establishments at Brussels, Ghent, Liége, Antwerp, &c.; as well as to the grotto of Haux, the marshes of Hasselt, &c. English botanists are especially invited to take part in this meeting. The districts to be visited are stated to be of unusual interest from a botanical point of view.

THE subscriptions to the Sedgwick memorial give promise that a handsome museum will be erected to his memory. The amount already promised is very considerable. The Chancellor of the University, the Duke of Devonshire, heads the list with a donation of 1,000*l*. The High Steward, the Earl Powis, contributes 200*l*.; the Prince of Wales, 100 guineas; the Vice-Chancellor., Dr. Cookson, the two representatives in Parliament, the Right Hon. S. H. Walpole and Mr. Beresford Hope, as well as a large number of other gentlemen give 100*l*. each. The Earl of Derby has promised 200*l*., Prof. Selwyn, 500*l*.; the Master of Trinity College, 200*l*.; Prof. Lightfoot, 200*l*.

THE Royal Horticultural Society's Show at Bath was opened on Tuesday, and continues till Saturday.

THE official report of the Secretary of the U.S. Navy, respecting the Arctic exploring ship *Polaris*, dispels the suspicions respecting the manner of Captain Hall's death, and shows that the separation of the crew was accidental, but does not account for the failure of the *Polaris* to rescue the men on the ice. Important scientific results have been obtained. The supposed open Polar Sea proves to be a sound opening into Kennedy Channel, with an inlet on the east, probably marking the northern shore of Greenland. The *Tigress*, which has been purchased by the Navy department for the relief expedition, will start early in July.

THE Council appointed at the Conference of the Trades Guild of Learning, recently held at the Society of Arts, met on Saturday last. Amongst other business transacted it was resolved

that in addition to various other eminent men, the following, as representatives of literature, science, and art, be invited to become vice-presidents of the guild:—Prof. Huxley, Sir Francis Grant, Mr. Alfred Tennyson, Dr. W. B. Carpenter, Prof. Tyndall, Sir Antonio Brady, Lord Lyttelton, Mr. Thomas Hughes, M.P., Mr. J. A. Froude, and Sir Sterndale Bennett. It was further resolved that the annual subscription for ordinary members be one shilling or upwards, and for associate members one guinea or upwards; that application should be made for donations to meet the preliminary expenses, and to furnish an income until the society is self-supporting; and that a prospectus of the objects and plans of the society should be issued as soon as possible.

COMMODORE SELFRIDGE has returned to the Navy Department at Washington, bringing with him the materials for presenting a detailed report of his exploration upon the Isthmus of Darien during the past winter in reference to the construction of an inter-oceanic ship-canal. The result of his inquiries has been much more favourable than was anticipated, and it is now estimated that only twenty-eight miles of canal need be constructed, the remainder of the distance consisting of the perfectly navigable waters of the Atrato, Doguado, and Napipi rivers. A tunnel will still be necessary, as estimated on a previous exploration, but this will only require to be three miles in length, instead of five, and it is estimated that the entire distance can be completed at a cost of less than 70,000,000 dols. Twenty-two miles of the canal are over an almost level plain, and only nine locks in all will be needed.

WE have just received the first number of the Bulletin, or Proceedings of the Society of Natural History of Buffalo, New York. Four similar numbers are to be issued each year, with a few plates. The number before us is solely occupied by the work of Mr. Aug. R. Grote, who contributes four papers describing new North American Moths, and giving catalogues of the Sphingidae and Zygaemidae of North America, followed by conclusions drawn from a study of the genera Hypena, and Herminia.

SINCE the diffraction spectrum differs from a prismatic spectrum of the same length in having the less refrangible rays more widely dispersed, it some time ago suggested itself to Prof. C. A. Young that a so-called *gitter-platte* or "grating" of fine lines might advantageously replace the prisms in spectroscooes designed for the observation of the solar prominences through the C line. Having recently obtained one of the beautiful gratings ruled upon speculum metal, having a ruled surface of something more than a square inch, the lines being spaced at intervals of $\frac{1}{6480}$ of an inch, he combined this with the collimator and telescope of a common chemical spectroscope, thus getting an instrument furnishing a spectrum of the first order, in which the D lines are about twice as widely separated as by the flint glass prism of 60° belonging with the original instrument. In the neighbourhood of C the dispersion is nearly the same as would be given by four prisms. The spectra of the higher orders are generally not so well seen on account of their overlapping each other, but fortunately with one particular adjustment of the angle between the collimator and telescope, the C line in the spectrum of the third order can be made to fall in the vacant space between the spectra of the second and fourth orders. On applying the new instrument to the equatorial, Prof. Young found that in the first order spectrum he could easily see the bright chromosphere lines C, D_3, and F; he could also, though with great difficulty, make out $H\gamma$, (2796K). On opening the slit the outline of the chromosphere and the forms of the prominences were well seen, both in the spectra of the first and third order. The grating is much lighter and easier to manage than a train of prisms, and if similar ruled plates can be furnished by the opticians at reasonable prices and of satisfactory quality, it would seem that for observations upon the chromosphere and prominences they might well to some extent supersede prisms.

THE Eleventh Annual Report of the Free Libraries Committee of Birmingham is very carefully drawn up. It contains some valuable analytical tables showing the average numbers of those who daily take advantage of the library, the ages of the readers, their occupations, along with the number of volumes issued to readers of each occupation, and tables showing the books most in demand. From the latter item we are glad to see that science in its various departments comes in for a very fair share of attention. In April 1872 the Reference Library and the Art Gallery were thrown open to the public on Sunday afternoons, and to judge from the statistics, the privilege has been taken considerable advantage of, especially by those who have least time during the week for mental improvement.

IN the last number of the *Journal of the Statistical Society* is an interesting paper by Mr. F. Galton, F.R.S., on the Relative Supplies from Town and Country Families to the population of future generations. Mr. Galton took for the purpose of comparison, from the census returns, 1,000 families belonging to Coventry, in which there are various industries, and where the population is not increasing, and 1,000 families from small agricultural parishes in Warwickshire. After careful comparison and calculation, based on ascertained data, Mr. Galton concludes that the rate of supply in towns to the next adult generation is only 77 per cent., or, say, three-quarters of that in the country. In two generations the proportion falls to 59 per cent., that is, the adult grandchildren of artisan townsfolk are little more than half as numerous as those of labouring people who live in healthy country districts.

THE Reports and Proceedings for the year 1872–3 of the Miners' Association of Cornwall and Devon, contain some good papers, mostly of a practical nature, in connection with mining.

WE have received the Monthly Notices of the papers and proceedings of the Royal Society of Tasmania for 1870, 1871, and the half of 1872. A great part of them are occupied with valuable meteorological observations and statistics, and from the reports of the society's meetings and the numerous papers printed *in extenso* on subjects connected with all departments of science, we judge the society to be in a healthy condition. As might naturally be expected, many of the papers are devoted to the practical aspects of science, to pisciculture, arboriculture, agriculture, the rearing of sheep, &c.

WE would recommend to anyone visiting Derbyshire, especially the district around the Peak, Mr. Bates's little "Handbook to Castleton and its Neighbourhood," containing very full and well-compacted information on all the places of interest around. There is a useful section on the geology, mineralogy, and botany of the district, and we believe that Mr. John Tym, of Castleton, the publisher of the book, well known as a geologist, will willingly give anyone who calls at his shop, information on the natural history of the district.

WE would recommend to all Londoners who are at a loss how to spend an occasional holiday to procure the summer edition of Mr. Henry Walker's "Half-Holiday Guide," which is wonderfully cheap considering the quantity of matter it contains. It would take a few summers of half-holidays to exhaust all the charming resorts around London he describes. The book also contains much useful information for the botanist, geologist, ornithologist, entomologist, and microscopist, as well as with regard to various sports. Mr. Walker should, however, cease to quote so much irrelevant verse.

THE following additions have been made to the Brighton Aquarium during the past week:—Two Puffins (*Fratercula arctica*); small Crocodile (*Crocodilus sp.*) from Sumatra, presented by Captain Murray; Bass (*Labrax lupus*); Black Bream (*Cantharus lineatus*); Streaked Gurnards (*Trigla lineata*); Mackerel (*Scomber scomber*); Lumpfish (*Cyclopterus lumpus*); Grey Mullet (*Mugil capito*); Ballan Wrasse (*Labrus maculatus*); Flounders (*Pleuronectes flesus*), fresh-water variety, presented by F. J. Evans, Esq.; Herring (*Clupea harengus*); Conger Eels (*Conger vulgaris*); John Dorée (*Zeus faber*); Sea Horses (*Hippocampus ramulosus*) from the Mediterranean; Octopus (*Octopus vulgaris*); Oysters (*Ostrea edulis*); Zoophytes (*Actinoloba dianthus*), (*Sagartia nivea*), (*S. miniata*), (*Alcyonium digitatum*), (*Tubularia indivisa*).

THE additions to the Zoological Society's Gardens during the past week include a Dormouse Phalanger (*Dromicia nana*) from Tasmania, presented by Mast. W. F. Stratford; a Coati, brown variety (*Nasua nasica*) from S. America, presented by Mr. G. P. Crawford; a Lion (*Felis leo*) from Africa, presented by the Hon. M. E. G. Finch Hatton; a Rhesus Monkey (*Macacus erythreus*) from India, presented by Mr. J. C. Freeman; a Tasmanian Rat Kangaroo (*Hypsiprymnus cuniculus*), presented by Mr. J. Shelton; a Garnet's Galago (*Galago garnetti*) from E. Africa, presented by Mr. Bartle Frere; two horned Lizards (*Phryrosoma cornutum*) from Texas, presented by Mr. W. L. Booker; a Clifford's Snake (*Zamenis cliffordii*) from Cairo, presented by Mrs. E. Liveing; a black Stork (*Ciconia nigra*), two white Storks (*C. alba*), and a Spoon-bill (*Platalea leucorodia*), purchased; a red Kangaroo (*Macropus rufus*), and a Fallow Deer (*Dama vulgaris*), born in the Gardens.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 15.—"On the Heating of a Disc by Rapid Rotation *in vacuo.*" By Prof. Balfour Stewart, M.A., F.R.S., and Prof. P. G. Tait, M.A.

In two previous communications to this Society, we gave an account of some experiments which we had made up n the heating of a disc through rotation *in vacuo.* In these experiments the increase of radiation of the heated disc was observed by means of a delicate thermopile and galvanometer. Three aluminium discs of various thicknesses and one ebonite disc were used, and the results derived from the experiments were as follows:—

(1) The heating effect observed appeared to be independent of the density, and of the chemical constitution of the residual air and vapour surrounding the discs.

(2) The quantity of heat developed under similar circumstances of rotation in three aluminium discs ·05, ·0375, ·025 of an inch in thickness respectively appeared to be the same, inasmuch as the relative thermometric effect for these discs varied inversely as their thickness.

(3) Besides the heating effect alluded to in (1) and (2), there was found to be, when the vacuum had been recently made, a strictly temporary effect, sometimes in the direction of heat, sometimes in that of cold, owing probably to the condensation or evaporation of small quantities of aqueous vapour; but this effect was only noticeable during rotation, disappearing the moment the motion was stopped.

In June 1871 the experiments were resumed. In the mean time the apparatus had been fitted with an arrangement working through a barometer-tube, by means of which, instead of trusting to radiation, the disc itself might, after rotation, be tapped by means of the pile, which could be brought up to it and then withdrawn. By this means a much larger effect might be obtained, and it became possible, by varying the adjustment, to find according to what law the heat-effect varies with the distance from the centre.

These experiments were conducted in the following manner: The disc was first of all tapped before rotation several times; at each tapping the momentary swing of the needle was recorded, and the mean of the readings was regarded as indicating the state of the disc with respect to heat.

The disc was next tapped after rotation, and the difference between the readings before and after was taken as indicating the change in the state of the disc produced by rotation.

The results derived by tapping an ebonite disc were found to be very different from the radiation-results, inasmuch as in the former the effect of the pressure and quality of the residual air is very apparent, while in the radiation-results it is hardly perceptible. A probable explanation of this will be given afterwards, but in the mean time, in view of these results, it has been thought expedient to discuss them quite independently and by themselves, with the view of ascertaining whether they can best be explained by a gas-effect alone, or whether they likewise indicate a residual effect independent of gas.

With this object calling A B the results at $\frac{6}{20}$ and $\frac{3}{20}$ let us take $\frac{(A)+(B)}{2}$ as representing the *whole effect* at a pressure of $\frac{6}{20}$ in. due to whatever cause or causes. We thus obtain

	Dry hydrogen.	Dry air.	Dry carbonic acid.
Whole effect at $\frac{6}{20}$ . .	9·5	25·0	24·0

Again, let us suppose that (A) − (B) denotes the *gas effect* for $\frac{6}{20}$ in., and we obtain

	Dry hydrogen.	Dry air.	Dry carbonic acid.
Gas-effect at $\frac{6}{20}$ . . .	4·0	20·0	18·0

Finally, let us regard as *unknown residual effect* the difference between the *whole effect* and the *gas-effect*, and we obtain

	Dry hydrogen.	Dry air.	Dry carbonic acid
Residual effect . . .	5·5	5·0	6·0

Similar experiments with the same galvanometer were made with a disc of cartridge-paper, of which the pores were filled with solid paraffin.

Treating these results in the same manner as those of the ebonite disc, we obtain:—

	Dry hydrogen.	Dry air.	Dry carbonic acid.
Whole effect ($\frac{6}{20}$) . .	25·0	45·0	43·5
Gas-effect ($\frac{6}{20}$) . . .	4·0	20·0	23·0
Residual effect . . .	21·0	25·0	20·5

Now, if we suppose that there is only one effect due to gas, it follows:—

(*a*) That the proportion between the effects due to the various gases experimented on (and all of the same pressure) is nevertheless different for the two discs.

(*β*) That the proportion (for the same disc) between the effects due to the various gases experimented on is different according to the pressure.

If, however, we suppose that there are two effects, one of which is independent of the residual gas, we find:—

(*a*) That, as regards the *gas-effect*, the proportion between that due to the various gases is nearly the same for both discs. Thus in the ebonite disc we have 4, 20, 18, while in the paper disc we have 4, 20, 23 as representing the gas-effect for the various gases.

(*β*) That the *residual effect* in either disc is nearly the same for the various gases. Thus in the ebonite disc we have 5·5, 5·0, 6·0, while in the paper disc we have 21·0, 25·0, 20·5 as representing the residual effect for the various gases.

The results are thus much more simple on the hypothesis of two effects, one of these being independent of the residual gas, than on the hypothesis of only one effect.

It was next endeavoured to ascertain whether these two effects were differently influenced by a blind, and it was found that the proportion between the two effects is greatly altered by the blind, so that while the hydrogen effect is not much stopped, the other is diminished very considerably; it was therefore concluded that the residual effect is not much altered by a chamois leather blind.

It was suggested to us by Prof. Helmholtz that it would be desirable to ascertain whether any difference was produced in the results by loading the disc on one side; for if these results be due to vibration, it might be supposed that they would be affected by this means.

It has been seen that the residual effect obtained from a disc covered with chamois leather is approximately the same as that from an uncovered disc; this would appear to us to be against the vibration hypothesis.

In an experiment made the disc was covered with a chamois leather blind with a segment cut out.

From a mean of two sets of experiments we may conclude that this arrangement does not much influence the results.

The disc was next treated in the following manner :—

It was covered with a chamois leather blind tied into holes drilled in the disc, and having two pieces of different shape cut out. The experiments gave (for an atmosphere of $\frac{3}{20}$ dry hydrogen) tapping in A 54, tapping in B 56, while for an uncovered disc they gave 53 as the heat-result. All these experiments apparently combine to prove that the result is not due to vibration.

Our next experiments were made with the view of testing whether or not the two effects, the residual and the gas-effect, were resident in the same particles of the disc ; and for this purpose the experiments made immediately after rotation were compared with those made one minute afterwards.

The experiments available for this purpose are so numerous that they can bear splitting into two portions, in each of which the same result is seen.

Thus we have for an atmosphere of $\frac{3}{20}$ dry hydrogen, and as the mean of 30 individual comparisons.

Effect at first : Effect one minute after : : 1·30 : 1 ;

also, as the mean of 22 individual comparisons, we obtain the proportion of 1·19 : 1, while as the mean of the whole we obtain 1·25 : 1.

Treating in a similar manner the observations made with an atmosphere of $\frac{3}{20}$ hyd. + $\frac{6}{20}$ air, we obtain

As the mean of 25 comparisons	1·47 : 1.
As the mean of 21 comparisons	1·41 : 1,

while as the mean of the whole we obtain 1·44 : 1.

We therefore conclude that the residual effect is less diminished during the interval of one minute than the gas-effect.

We next made experiments with two aluminium discs ·05 and .025 of an inch in thickness respectively. These discs were covered on both sides with a coating of lampblack applied by negative photographic varnish.

From these experiments it was concluded that there are two effects which are differently distributed over the particles of the disc.

It also appeared that the effect for $\frac{3}{20}$ hyd. which may be supposed to represent the residual effect, and that for $\frac{3}{20}$ hyd. + $\frac{6}{20}$ air, which may be supposed to represent the gas-effect, are both diminished in very nearly the same proportion, namely 100 : 77, by a transference of the pile to a position nearer the centre of the disc. And it was furthermore concluded from the experiments that in an aluminium disc covered with varnish, as well as in a disc of ebonite, we may imagine the residual effect to be more deeply seated than the gas-effect.

We venture on the following as what appears to us to be the most probable explanation of the whole body of experiments, including those with radiation.

(1) There is a temporary heat or cold effect which may be supposed to arise in particles very slightly attached to the disc ; this is radiated off chiefly during rotation, and does not probably greatly affect the disc afterwards.

(2) There is a surface gas-effect, which in an aluminium and even in an ebonite disc is conducted into the interior as it arises, so that it does not greatly radiate during rotation of the disc. In a paper disc, however, which is formed of a badly conducting material loosely put together, part of the effect does escape as radiation during rotation.

(3) There is a residual effect, which is more deeply seated than the gas-effect. And inasmuch as radiation takes place from a perceptible depth, this effect is much more influential than the gas-effect in increasing radiation after rotation. In the case of a paper disc, this deeply seated effect will be less diminished by radiation during rotation than the gas-effect, and therefore after rotation in such a disc we might expect the gas-effect to be peculiarly small.

In the course of these experiments we have endeavoured to prove that this residual effect is not caused by vibration. The radiation-experiments with aluminium discs of three different thicknesses went, on the other hand, to show that it was of the nature of a surface-effect. This is confirmed by the results derived from tapping ; for, in the first place, the experiments with aluminium discs show that the two effects (the residual and the gas-effect) are probably distributed in the same proportion, going from the centre to the circumference of the disc. Again, taking the two discs of thickness ·05 and ·025 of an inch, we obtain the following results :—

	Effect for $\frac{3}{20}$ hyd.	Effect for $\frac{3}{20}$ hyd. + $\frac{6}{20}$ air.
Thin disc ...	48 (22 observations).	228 (10 observations).
Thick disc...	29 (20 observations).	108 (10 observations).

Now, allowing for errors of experiment, we see that the residual, as well as the gas-effect, is reduced to about one-half for the thick disc.

Again, an experiment of a similar nature gave the effect for $\frac{3}{20}$ hyd. in an ebonite disc of $\frac{1}{10}$ in. in thickness = 33 against a result = 55 for the thin ebonite disc. Unfortunately it was omitted to make a comparison with these two discs for the gas-effect ; nevertheless these results are all in favour of the residual effect being a surface-effect.

Our conclusion from the evidence before us is, that the residual effect is a surface-effect more deeply seated than the gas-effect, but distributed outwards from the centre to the circumference, very much in the same manner as the gas-effect. The residual effect likewise appears able to penetrate a chamois leather blind without any perceptible diminution. We regard these conclusions as preliminary, and shall endeavour in our future experiments to procure additional evidence of these properties of the residual effect, as well as to obtain new facts regarding it. In the meantime, as the subject is one of interest, and has been already too long delayed, we have not hesitated to bring these results before the notice of the Royal Society.

Geological Society, June 11.—Prof. Ramsay, F.R.S., vice-president, in the chair.—The following communications were read :—"On the nature and probable origin of the superficial deposits in the valleys and deserts of Central Persia," by W. T. Blanford. The general results may be summed up as follows :—Persia has undergone a gradual change from a moister to a drier climate simultaneously with the elevation of portions of its surface, resulting first in the conversion of old river-valleys into enclosed basins containing large lakes, probably brackish or salt. Then, as the rainfall diminished, the lakes gradually dried up, leaving desert plains. The amount of subaërial disintegration among the rocks of the high ground he considered to be in excess of the force available for its removal, the water which now falls only sufficing to wash the loosened materials from the steeper slopes into the valleys, and hence the valleys in the upper parts are gradually being filled up with coarse gravel-like detritus, just as their lower portions have been already hidden beneath lake-deposits.—"On *Caryophyllia Bredai* (Milne-Edwards and Haime) from the Red Crag of Woodbridge," by Prof. P. Martin Duncan, F.R.S. The author recorded the occurrence in the Red Crag of the Woodbridge district of a variety of *Caryophyllia Bredai* (Milne-Edwards and Haime).—"On the Cephalopoda-bed and the Oolite Sands of Dorset and part of Somerset," by James Buckman, F.L.S. From an investigation of the Cephalopoda-bed in quarries at Bradford Abbas in Dorsetshire, the author comes to the conclusion that it is quite distinct from the Cephalopoda-bed of Gloucestershire, and that it is the representative of the Rubbly Oolite at the top of Leckhampton Hill and Cold Comfort, and of the Gryphite and *Trigonia*-beds of the neighbourhood of Cheltenham. The Gloucestershire Cephalopoda-bed he regards as situated close to the bottom of the Inferior Oolite series ; and this is also the position to which he refers the sandy beds above mentioned.—"*Cetarthrosaurus Walkeri* (Seeley), an Ichthyosaurian from the Cambridge Upper Greensand," by H. G. Seeley, F.L.S. In this paper the author described a small Ichthyosaurian femur, discovered by Mr. J. F. Walker in the Upper Greensand of Cambridge. He noticed the general characteristics of the femur in Ichthyosaurians, and pointed out, as the chief peculiarities of the bone that he was describing, the subovate form of its head, and the presence of large flattened lateral trochanters, which, if of equal dimensions on both sides of the bone, would have made its greatest transverse measurement greater than its length. Upon this bone he proposed to found new a genus, *Cetarthrosaurus*.

Royal Astronomical Society, June 13.—Prof. Cayley, F.R.S., president, in the chair.—S. J. Lambert, of Newton Observatory, Auckland, was elected a Fellow of the Society.—The Rev. J. Vale Mummery presented a large photographic portrait of Mrs. Somerville. He said that the Society had long been possessed of a portrait of Miss Caroline Herschel, and he was glad now to be the means of finding her so fitting a companion. Mrs. Somerville and Miss Herschel had been admitted as honorary members of the Society on the same evening in 1834. They had long been separated, first by distance and then

by death, and it was only fitting that their portraits should now be hung together on the walls of the Society.—Paper "On a stereographic projection of the transit of Venus in 1882," by R. A. Proctor. The author said that his paper was intended to show the desirableness of limiting the preparations for Halley's method to the transit of 1874. In the transit of 1882 the lines bounding the region where the whole transit can be seen will lie much closer. This is the natural effect of the transit lasting only six hours. Again, the southern pole where difference of duration is greatest, instead of lying within the region where the whole transit can be seen as in 1874, lies outside that region. It should be remembered also that in searching for suitable places of observation a fringe of 10° wide, measuring along the lines where the beginning and end of the transit are seen at sunrise or sunset, must be thrown out of account. Taking this into account the transit of 1882 is seen to be very little suited for Halley's method. Maps were shown to illustrate the paper.—"On occultations of stars by the moon and eclipses of Jupiter's satellites," by the Rev. R. Main. This paper contained a very extensive table of observations of eclipses of Jupiter's satellites. Several such sets of observations have recently been received by the Society, and it was remarked that a paper on the subject read by the Astronomer Royal last year was beginning to bear good fruit.—"Note on the discovery of a new minor planet, No. 131," by Dr. Peters. This is the nineteenth planet discovered by Dr. Peters. Dr. Luther has also discovered 19. Thanks to the American telegraphic system, it has already been observed in England as well as at Leipzig and Marseilles.—"Note on the Mass of Jupiter," by W. T. Lynn. In 1866, he had had the honour of laying before the Society an account of a determination of this element by Prof. Krüger, of Helsingfors. That determination having been recently improved by the aid of subsequent observations, the result was communicated by the author to the *Astronomische Nachrichten* (No. 1,941.) Mr. Syme has, in this "Note," placed it in juxtaposition with the determinations by Airy, Bessel, Jacobs, and Möller. The agreement thus shown is very satisfactory, especially as the methods employed are different—Airy, Bessel, and Jacobs deducing Jupiter's mass from the motions of his satellites, Möller from those of Faye's Comet, and Krügen from those of the planet Kemis. This important element in the solar system may be considered as well established.—"Note on Dr. Oudeman's Photographs of the Solar Eclipse of Dec. 11, 1871," by Col. Tennant. He had received two paper copies of the photographs taken in Java. He could recognise almost every depression of outline as in the Indian photographs, but there was much less detail. He thought we might learn something from them as to photography. It was evident that the light was more intense than in the Indian photographs, but the exposure for a short time had not had the effect of producing the halation which was there visible. He was convinced that in future eclipses it will be better to use a reflector.—Mr. Ranyard remarked that the paper copies of the Dutch photographs which he had seen had been printed from enlargements on glass in which the moon had been stopped out with black paper, or some other material. On measuring, he had found that the body of the moon, as given in the photographs, was by no means circular; and Mr. Davis had pointed out to him that the irradiation under the prominences was perfectly sharp at the edges as it would be when printed through a paper notch. It was therefore unfair to institute any comparisons as to the amount of the irradiation in these and in the other photographs.—"Note on the sympathetic influence of clocks," by Mr. William Ellis. He had been testing a number of clocks placed upon a wooden frame at the Royal Observatory. At first he found a sympathetic influence, but when the frame was considerably strengthened, so as to prevent vibration, they ceased to influence one another. He concluded that the popular notion as to the vibrations in the air produced by the swing of one pendulum having any susceptible influence on another swinging near to it was erroneous.—"On a recording micrometer," by Mr. W. H. Christie. This contained a description of two rather elaborate instruments for recording the transits of stars by pricks on a long strip of paper. It is intended to make experiments as to the possible use of the instruments at Greenwich.—Proposal to determine the solar parallax by observations of the opposition of the planet Flora. M. Galle invited the assistance of English and Australian astronomers. He had prepared and submitted to the Society a long list of suitable comparison stars.

Linnean Society, June 19.—Mr. Bentham, president, in the chair.—Prof. P. M. Duncan read a paper on the Development of the Gynæcium and method of Fertilisation of the Ovule in *Primula vulgaris*. Prof. Duncan had carefully followed the account given by Duchartre of the mode of development of the ovule in Primulaceæ, from which he differed in many important points, believing that the French observer had been led into error by dissecting only a cultivated and therefore to some extent abnormal variety. In tracing the development of the floral organs Duchartre states that he first of all detected the calyx, then the stamens, and finally the pistil, the placenta being formed in the centre of the cavity of the pistil, and never connected with the ovarian wall. With this statement Payen agrees. Dr. Duncan's observations agreed with these as far as the formation of the calyx and stamens was concerned; but within the latter he found simply a mamillary process. At the next stage there was a very short style, solid and not perforated, the ovarian wall including the placenta on which were the rudimentary ovules; the ovarian wall does not grow up over the placenta, but is produced from it by a kind of differentiation; subsequently the style lengthens and the small stigma is produced. The ovules appear in a spiral series, and are recognised by their power of reflecting light; the summit of the placenta has never any connection with the style. The ovule consists of nothing but a single integument and an embryo-sac: there is no inner integument and no nucleus. The lower portion of the tissue of the style is absolutely impervious to the pollen-tubes; and if these could enter the ovary in this way, the micropyles are in such intimate contact with the placenta, that they could never be reached by the tubes from the cavity of the ovary. Dr. Duncan has detected the passage of the pollen-tubes actually through the tissue of the placenta itself, from which they again emerge to reach the micropyle of the ovule. In the discussion which followed, this view of the course of the pollen-tubes was confirmed by Dr. T. S. Cobbold.—Dr. Hooker read a paper by the Rev. C. New, on the sub-alpine vegetation of Kilma njaro. This is the only tropical African alpine flora with which we are acquainted; the mountain being situated in Eastern Africa, 3° S. lat., rising to a height of 20,000 ft., or nearly 5,000 ft. above the snow-level. The flora is essentially that of the Cameroons. The flora may be divided into seven regions of successive heights; the 1st is the inhabited district, with plantains, maize, &c.; the 2nd region is jungle; the 3rd is a forest of gigantic trees covered with moss, the herbaceous vegetation being essentially European, with the dock and stinging-nettle, frosts almost every night; the 4th consists of green hills covered with clover; the 5th is heath; the 6th bare hills; the 7th, everlasting snow. Of the fifty species contained in the collection, twenty were from the zone immediately beneath the perpetual snow; nearly all were of South African genera, very few European, and no new species not already known from the Cameroons. The flora is therefore essentially South African.

Meteorological Society, June 18.—Dr. J. W. Tripe, president, in the chair.—The following papers were read:—On some results of temperature observations at Durham, by John J. Plummer.—On the Meteorology of New Zealand, 1872, by C. R. Marten.—On the Climate of Vancouver Island, by Robert H. Scott, F.R.S.—Meteorological Observations at Zi-Ka-Wei, near Shanghai, by Rev. A. M. Colombel, with note by Rev. S. J. Perry, F.R.A.S.—Notes on the connection between Colliery Explosions and Weather, by R. H. Scott, F.R.S., and William Galloway.—Distribution of Rainfall Maxima in Great Britain and Ireland between the years 1848 and 1872 inclusive, by W. R. Birt, F.R.A.S., and note on the heavy Rainfall of March 4 at Natal, by R. J. Mann, M.D., F.R.A.S. The ordinary meeting was then adjourned and the Annual General Meeting was held, and the Report of the Council read. The Report stated that the Council had much pleasure in congratulating the Society, at the close of the twenty-third session, upon the termination of a year which will bear favourable comparison with any that precedes it, whether regard be had to the character of the papers read, to the attendance at the periodic meetings, to the number of new Fellows elected, or to the activity and interest evinced in the general proceedings. It was stated that it had been found necessary to hold an extra meeting in May to enable all the papers which had been received to be presented before the Society; and the Council had the gratification to announce that it is in contemplation to hold eight monthly meetings next session, instead of six as has been the practice hitherto. The number of new Fellows added to the Society during the year had amounted to 35, the accession thus indicated being considerably larger than upon any years since 1864. Reference

was made to the library, the financial affairs, the proposed alterations of the bye-laws, and the recent meteorological conference at Leipzig; and the Council concluded by stating that they had had under consideration that evening a letter from the Board of Trade with reference to sending a representative to the Meteorological Congress to be held at Vienna in September next. The President then delivered an Address in which he chiefly referred to the progress of the Society during the two years that he had occupied the presidential chair. The following gentlemen were elected officers and council for the ensuing year:—President—Dr. Robert James Mann, F.R.A.S. Vice-presidents—Arthur Brewin, F.R.A.S., George Dines, Henry Storks Eaton, Lieut.-Col. Alexander Strange, F.R.S. Treasurer—Henry Perigal, F.R.A.S. Trustees—Sir Antonio Brady, F.G.S., Stephen William Silver, F.R.G.S. Secretaries—George James Symons, John W. Tripe, M.D. Foreign Secretary—Robert H. Scott, F.R.S. Council—Charles Brooke, F.R.S., Charles O. F. Cator, Rogers Field, C.E., Frederic Gaster, James Glaisher, F.R.S., John Knox Laughton, F.R.A.S., William Carpenter Nash, Thomas Sopwith, F.R.S., Rev. Fenwick W. Stow, M.A., Capt. Henry Toynbee, F.R.A.S., Charles Vincent Walker, F.R.S., E. O. Wildman Whitehouse, C.E.

Berlin

German Chemical Society, June 9.—A. W. Hofmann, president, in the chair. A. Behr and Van Dorp report oxide of lead heated in iron tubes to be a good oxidising agent for organic vapours: $C_6H_4(CH_2)_2$ yielding $C_6H_4(CH)_2$, &c.—E. Salkowsky has found that taurine escapes digestion in the human body to a large extent. A small quantity of the following compound, however, passes into the urine; a crystallised acid of the empirical formula, $C_3H_8N_2SO_4$, forming quadratic plates, which are easily soluble, and giving well-crystallised salts with Ba, Ag, &c. With baryta water it yields taurine, carbonic acid and ammonia. The acid appears to be a substitution product of our hydrogen in taurine through carbaminic acid. Dr. Salkowsky took 5 grammes of taurine for twelve days following without suffering any great inconvenience to his health.—T. Thomsen sent in the results of very numerous experiments on the heat absorbed or developed by dissolving various salts in water. The same *savant* attacks the calorimetric method employed by Berthelot, and disputes his conclusions as to the existence of a hydrate $HCl + 8H_2O$.—K. Heumann has found that copper in contact with sulfide of ammonium becomes covered with crystals of subsulfide Cu_2S, according to the reaction $2CuO + 2(NH_4)_2S = Cu_2S + 4NH_3 + 2H_2O + S$.—H. v. Gegenfeld reports on the action of hypochlorous acid HClO on allylic chloride. The dichlorhydrine thus formed he considers as isomeric with that prepared from glycerine, while L. Henry obtained a body through the same reaction, which he considers as identical with ordinary dichlorhydrine.—L. Bisschopinck has studied the amides and the nitrites of the three chloracetic acids, particularly with regard to their physical properties. The most prominent result is the following irregularity in the boiling points of the nitriles, namely:—

$CH_3.CN$	boils at	81— 82°
$CH_2Cl.CN$	,,	123—124°
$CHCl_2.CN$	,,	113—113°
$CCl_3.CN$	,,	83— 84°

The foregoing remarks were accompanied by a note of M. L. Henry on the boiling-points of the cyanides of negative radicals. He points out that if in HCN, H is replaced by a negative element or radical, the boiling point sinks; thus HCN 26°, Cl.CN 15°, CN.CN — 21°, adding other examples, and the attempt of an explanation of this exceptional phenomenon. The same chemist has continued his researches on propargylic alcohol C_3H_3OH. He has found its boiling point equal to 114°, and he has prepared the bromide, the iodide, the sulfocyanide, and the acetate belonging to it. In treating brominated allylic alcohol $C_3H_4Br.OH$ with potash, he obtains besides propargylic alcohol an ether $(C_3H_4Br)_2O$, and perhaps also propargylic ether, which has not as yet been obtained in the pure state.

Paris

Academy of Sciences, June 16.—M. de Quatrefages, president, in the chair. The following papers were read:—On the combustion heat of formic acid, by M. Berthelot.—On the alloys used for gold coinage, by M. Eug. Pelegot. The author advocated the addition of zinc to the alloy, and at the same time the reduction of the gold to a very great amount. He mentions with favour alloys containing from 48 to 66 mill. zinc, 354 to 372 copper, and 580 to 581 gold.—A report on the papers on *Phylloxera*, by MM. Duclaux, Max. Cornu, and L. Faucon was presented.—On the complete movements of a ship oscillating in calm water, by MM. O. Duhil, de Benazé and P. Risbec. The authors gave an account of their experiments on the *Elorn*, a vessel of 100 tons displacement.—Photo-chemical researches on the use of gases as developers, and on the influence of physical conditions as regards sensitisation, by M. Merget, was a paper on some of the chemical phenomena of photography.—On a scientific balloon ascent on the 26th April, 1873, by MM. Crocé-Spinelli, Jobert, Pénaud, Petard, and Sivel.—Announcement of the discovery of Planet 132 at Washington on the 14th June, by Prof. Henry.—Researches on electricity produced by mechanical actions, &c., by M. L. Joulin. Researches on essence of alan-gilan (*Unona odoratissima*), by M. H. Gal. The author has discovered benzoic acid in this essence, and believes that this is the first instance of this body being found in an essence, it having hitherto been found only in the balsams.—Contributions to the history of the histologic constitution of Moitg's glarin, by M. A. Bechamp. This paper related to the gelatinous body found in the sulphurous springs of the Pyrenees. The author finds that microscopic examination shows it to be a mass of microzymes imprisoned in a hyalin matrix. He has tried various experiments on its action as a ferment.—On the estimation of the total nitrogen in manures, by M. H. Pellet.—On the estimation of phosphoric acid in natural phosphates, super-phosphates, and manures, by M. H. Joulie.—On a process for the estimation of hæmoglobin in blood, by M. Quinquaud.—On the determination of the mechanical equivalent of food, by M. A. Sanson. The author pointed out the immense value to all employers of animal motive power, such as military authorities, &c., of the value of a method for ascertaining the value in work of the forage they use for their horses. He estimated the value of 1 kilo. of protein in a good average ration, as, in round numbers, 1,600,000 metre-kilograms.—Experimental researches on the influence of barometric changes on the phenomena of life, 11th note, by M. P. Bert.

DIARY

THURSDAY, June 26.

Society of Antiquaries, at 8.30.

FRIDAY, June 27.

Quekett Club, at 8.

SATURDAY, June 28.

Geologists' Association.—Excursion to Hatfield.

TUESDAY, July 1.

Society of Biblical Archæology, at 8.30.—The Fall of Nineveh and the First Year of Nebuchadnezzar, King of Babylon: J. W. Bosanquet.

WEDNESDAY, July 2.

Horticultural Society.—Rose Show.

BOOKS RECEIVED

English.—Field Pocket Book for the Auxiliary Forces: Colonel Sir Garnett Wolseley (Macmillan and Co.).—Education of Man (Charles Griffin & Co.)—Light Science for Leisure Hours. 2nd Series: R. A. Proctor (Longmans & Co.).—The Old Faith and the New: Dr. F. Strauss (Asher & Co.)—The Scholar's Arithmetic: Lewis Hensley (C. P. S. Macmillan & Co.).

CONTENTS

THURSDAY, JULY 3, 1873

AN ORDER OF INTELLECTUAL MERIT

THE many obvious objections that may be urged against the well-meant proposal which Earl Stanhope brought forward in the House of Lords the other evening, for the creation of an Order of Merit to confer upon men who have deserved well of their country in Literature, Science, and Art, have already been pretty fully discussed both in the Upper House itself, and by the daily press. Happily "It is not now as it hath been of yore;" the classes for whose behalf it is sought to create a special Order of Merit, are getting to be regarded as less and less a peculiar people, both by themselves and by the public generally. To many it appears that the creation of any such order would be going in the face of the progressive tendencies of the age, and, we are confident, would not be in accordance with the desires of many of the men whom Lord Stanhope is sincerely anxious to honour. It is well-known, that over and over again have both academical and imperial honours been refused by men whom all acknowledge to have produced works that must be placed in the highest rank of intellectual products, and they spurn patronage.

The matter is not, however, all one way. The medals conferred by the Royal Society are really the decorations of an Order of Merit, election to which, however, lies in the hands of competent men; and much of the objection to the creation of an Order of Merit, such as that proposed by Lord Stanhope, would be done away with if Government were composed of men as competent to select the candidates for such an honour, as are the Fellows of the Royal Society. No doubt as civilisation based on Science advances, a Government competent to elect to such an order, as well as of performing efficiently all the other functions of a model Government, will be found at the head of this great country.

Speaking specially for men of Science, for men who devote to the advancement of scientific knowledge what leisure they have to spare from the necessary work of bread-winning, we must at once point out a tremendous difference between them and those who are generally classed with them.

The work of the artist and the author is always a marketable commodity—sometimes a very marketable one—while the investigation of new scientific truth is absolutely unremunerative; all the same, we may safely say that they seek no such recognition from the State as is indicated in Lord Stanhope's proposal.

From the tenor of all the speeches in the Upper House on Friday night, even those adverse to the creation of a special Order of Merit, we judge that the Government, as well as the House of Lords, believes that men who attain eminence in Science are as deserving of recognition by the State as men who have distinguished themselves in the army or navy, in diplomacy or politics. If this is so, then we are sure we speak the wishes of the great majority of scientific men when we say that they are willing to dispense with all hope of ever obtaining any honour from the State, if Government would do what is without doubt its duty,—enable those who have shown themselves competent to pursue original scientific research, to devote all their time to this object without care as to the means of living.

Most of those who, not being rich men, have done most to advance scientific knowledge have done so in moments snatched from the duties imposed upon them by the necessity of procuring the wherewithal to support life. Many who do the most valuable work in Science, which is generally *not* the work that is most volubly brought before fashionable audiences, are compelled, for bare life, to adopt some profession, and almost the only profession open to men who have qualified themselves for thorough scientific research, is the profession of teaching. This profession, it is well known, is one demanding, for the thorough performance of its duties, a very large expenditure of the highest energy as well as of time, so that men of Science of the class we are speaking of, who are compelled to adopt it, have but a small amount of energy and little time left to devote to that pursuit on which their heart is set, for which their whole training has qualified them, and in which they have shown themselves competent to attain the highest results;—results of the greatest and most wide-spread value both to our own country and to humanity generally. Is it not shameful then, nay does it not argue the greatest blindness on the part of Government to the best interests of the country, that these men should be compelled to expend the very best of their valuable and well-skilled energies in the drudgery of a profession for which they may by no means be peculiarly fitted, merely to keep the life in their bodies, while but a very moderate expenditure on the part of the State, would enable them to devote, without dread of coming to want, the whole of their power to the pursuit of that research, from which the country already has reaped the highest benefit? No man whose opinion is of any value, not even any member of Her Majesty's Government, we believe, doubts the eminently practical utility of scientific research, and the dependence of our country for its foremost place among the nations of the world, that it should have at its disposal the highest and latest results of such research. Instead then of devising new and empty honours wherewith to reward men who, amid a life passed in the worry and struggle for existence, have been able to push forward scientific knowledge a short stage, would it not be honouring the pioneers of Science far more, and at the same time making an investment which ere long would be repaid a hundredfold, if Government would only bestow upon these men the means wherewith to do thoroughly, and with all their might, the unspeakably valuable work which at present they can only do by snatches, or be compelled to give up when probably it is about to bring forth noble results? If Lord Stanhope and those in both houses of Parliament who have the wisdom to see wherein the true glory and highest good of their country consist, would only set themselves earnestly to devise some plan whereby scientific research could be pursued under the most favourable circumstances, they would delight the hearts of scientific men infinitely more than if they heaped upon their heads all the honours of all the Courts of Europe.

COOKERY AT SOUTH KENSINGTON

THE most successful department of the International Exhibition this year is undoubtedly that connected with Cookery. Twice a day is a lecture delivered on some practical department of cooking, and at the same time a demonstration is given by a well-trained group of female cooks, in a conveniently fitted-up kitchen open to the audience. These lectures are the great attraction of the Exhibition, and many persons anxious to gain admission are turned away for want of space to accommodate them. This shows, at any rate, on the part of the public, an appreciation of the subject and a desire to be instructed as far as possible.

At the same time it is to be lamented that the class of persons who most need instruction in cooking do not attend. The charges of sixpence and a shilling for entrance to hear these lectures and see the cooking demonstrations must exclude the class of people for whom such instruction is most needed. Although there is a widespread notion that people in England do not know how to cook at all, yet we question very much if the civilised world produces better dinners than are to be found daily on the tables of the wealthy classes of England. They need not to consult economy either in the cost of materials of food or its preparation. For them lectures on cooking are not needed, and even their cooks, who get from fifty to a hundred pounds a year, could hardly be instructed by Mr. Buckmaster and his bevy of cleanly cooks. If anything is wanted by the wealthier classes, it is a more scientific knowledge of the nature of food and the processes by which it is prepared for digestion. This they will not get at South Kensington. Mr. Buckmaster's lectures are not intended as a scientific exposition of the chemical or physical properties of substances used as diet, or of the way in which they affect the palate or act on the body. They consist simply of directions how to prepare dishes, and the cooks in the kitchen follow his directions. There is no doubt that to thousands of people this is of great service. No housekeeper, however low in the scale of society, but must be benefited by seeing prepared poor man's soup, omelettes, macaroni, and Australian meat, in Mr. Buckmaster's kitchen. At the same time they will learn only how to imitate the methods of cooking they have seen: they will learn no principles. They will hear nothing about the nature of the materials they see cooked, unless it is that hot water and heat act upon them to produce the results they see. They will see eggs made into an omelette in a frying-pan, but hear nothing with regard to the nature of eggs, their value as an article of diet, and other means of cooking them besides frying.

Another defect we observed in these lectures was the truly British defect of ignoring weights and measures. Mr. Buckmaster's lecture sounded very like the magnification of a receipt out of an ordinary cookery book. Take a piece of this, a pinch of that, and a handful, a sprig, a few teaspoonfuls, and so on for every ingredient used. We know this is the rule of the kitchen, and any attempt to introduce scales and weights would be flouted with contempt. It is the same with temperature; water is called "cold," "warm," and "hot," without the slightest allusion to temperature. Surely in lectures like these accuracy ought to be studied; and when things can be measured and weighed, so good an opportunity of teaching the importance of this should not be lost. It is because of the neglect of these matters in the kitchens of our wealthier classes that they seldom have put on their tables dishes two days alike. Nay, we know more: we tasted some macaroni made by a cook who had been to Mr. Buckmaster's lecture, which was no more like the macaroni made in his kitchen than his was like plum pudding. This arose entirely from the cook not measuring rightly the time of cooking the macaroni and the quantity of the flavouring ingredients.

Now we do not say it is possible to teach all the science of cookery in one lecture, but we do say that it is possible to speak accurately about the *weights* of the materials used, the degrees of *heat* to be employed in cooking, and the *time* that things require to cook.

We throw out these suggestions in the hope of seeing them acted upon. There is no doubt that it would be attended with some difficulty. There is the Italian cook, Mr. Buckmaster's *chef*, and the four young female cooks, all not only to be educated, but to be got into the frame of mind to submit. We see also that there is a Cookery Committee, who would, we suppose, have to be consulted; but these gentlemen would, we are sure, assist in introducing so desirable a system of instruction. Mr. De Rivaz is on the Committee, and he is well known for his book on cookery called "Round the Table," as also for his receipts in the *Queen* newspaper.

Whether there is any intention on the part of this Committee to extend the lectures, and give a course on cookery comprising the teaching of the elements of the sciences involved in the facts acted upon in the kitchen, we do not know, but this would be a worthy object and probably would succeed, as the public is evidently disposed to listen to the subject. It must, however, be done at once, and done in the International Exhibition. It cannot be done at South Kensington; the experiment has been tried there and failed. The country gentlemen in the House of Commons do not see their way to voting public money for the instruction of people in London. Whether done in London or the country, such courses of instruction would be a capital way of getting a little scientific knowledge into the heads of people edgeways, as it were.

But now we come to the question of opening the present lectures to the poor. These lectures were intended for their instruction and got up in their interest, but they are conspicuous by their absence at these lectures. The whole Exhibition is open to them for a shilling, and when they have screwed this sum out of their hard-earned wages, and paid for a crust of bread and cheese and half-a-pint of beer, they have nothing to spare for learning cookery. Yet we are quite sure the money would be well spent. The persons in the community who suffer most for want of economy in cookery are the very poor. They buy their food in the most expensive way, by buying it in small quantities, and when they have got it they know less than any class how to cook. They know nothing of the way of making, or of the economy of using soup. They hardly know the difference between warm, hot, and boiling water in cooking food. The fact is, we believe, that half the food of this class is really lost for the want of a knowledge of the proper means of cooking it. To such people these lectures

should be open at the cost of a penny or twopence each lecture; and that each person of this class who attends the Exhibition should have the benefit of the lectures and demonstrations, these should be more frequent, and the theatre larger.

Something may be done before the Exhibition closes; but the cookery question is a permanent one. Cannot something be done to establish a School of Cookery, in which teaching such as is now going on at the International show can be carried on continuously? We can conceive such an institution possible, and even self-supporting. The whole of the middle and upper classes are interested in getting good cooks, and the school boards should be urged to allow their elder female pupils to attend the instructions given in such an institution. This would be an immense economy to all, for it would save a large portion of that waste which now goes on in every household, in teaching girls to become the sort of cooks they are.

If girls and women could be sent to such a school with a previous elementary knowledge of chemistry, physiology, and natural philosophy, they would derive more advantage than they would otherwise get from the necessarily short courses in such a school. In short it comes to this, that nearly all the details of practical life are dependent on facts which are comprehended in the various branches of scientific knowledge; and it is only as men and women are taught the nature of these facts that society can progress and man attain the highest possibilities of civilisation.

E. LANKESTER

COX'S POPULAR PSYCHOLOGY

What am I? A Popular Introduction to Mental Philosophy and Psychology. Vol. I. The Mechanism of Man. By Edward William Cox, Serjeant-at-law. (Longmans and Co.)

NO doubt many of the Serjeant's friends will read his popular introduction to the study of psychology, and think it very profound, and many of them, especially his lady friends, charmed with the vague denunciation of "Scientists" and materialists, the religious element, the quackery of science, and the scraps of poetry, will be able to tell him in all sincerity that they think it "a very nice book." But from those whose opinion is worth the paper it is written on, Mr. Cox has nothing to hope. The first sentence of the preface declares that "The study of psychology has not kept pace with the progress of the physical sciences." The truth of this statement must be painfully brought home to every real student of psychology, by the fact that a man possessing the intelligence and general culture of Mr. Cox could write such a book, and that educated people will be found to read it. We can agree with the author that there is at the present time room for a work presenting the leading truths of mental science in, if possible, a popular shape. But surely one qualification of the writer who would make such a book for the benefit of the "many persons who desire to obtain some knowledge of psychology, but who are deterred from its study by the ponderous volumes of abstruse argument . . . intelligible only to the far advanced philosopher," must be, that he is himself up with the best science of the day, that he has made himself acquainted with "the ponderous volumes of abstruse argument." Unfortunately Mr. Cox does not appear to have taken this view of the matter. In setting himself to produce an "outline of the science of psychology written in plain language," he has, in plain language, attempted work for which he is no more qualified than an ordinary farm labourer is qualified to translate Homer into the vernacular of his native village.

Like books of its class the volume before us is rich in curious absurdities of presumption. For instance, scientific men are very severely taken to task for their lamentable want of scientific method; and there is no end to the tirade against materialists, metaphysicians, and mental philosophers. Who these greatest of sinners are, we cannot tell; for Mr. Cox prudently refrains from mentioning names. Nor are we told very precisely what are the particularly damnable heresies with which they have poisoned the public mind; indeed, it would appear that mindful of the good old proverb that one cannot touch tar without being defiled, Mr. Cox has been careful to keep his own mind at an angry distance from all their evil thinking. It may however amuse some of our readers to know what, according to Mr. Cox, is not materialism, while it will enable all to estimate the claim of the writer to rank as a psychologist. This is spiritualism: "Rightly, then to conceive of spirit, the first step is clearly to comprehend that it is not, and cannot be, *immaterial*—but only that it is composed of very refined matter—so refined that it is imperceptible to our bodily senses, which are adapted only to perceive certain forms of matter that affect ourselves." "The soul, therefore, being composed of molecules infinitely finer than the molecules of the body—as fine possibly as those of the comet, could, with the utmost ease, permeate the body, infusing itself among all the atoms of which the body is built, and thus occupy the whole frame;" and as a consequence "the shape of the soul must be the shape of the body." The soul here spoken of is not "the mind" nor the "life," but the proprietor of the body, the mind, and the life. As Mr. Cox's "inquiry is designed to be purely *scientific*," and is "addressed mainly to those who reject the authority of the theologian," we must give one specimen of the scientific arguments, in support of the existence of this entity, which scientists in their stupidity have hitherto failed to appreciate. Here is the best one:—"Does any sane man ever talk or write of his mind or his life as 'Me?' Does he not always say '*my* mind,' '*your* mind, '*my* life,' '*your* life,'—that is to say 'the mind, the life, —that belongs to *me*,' 'the life—the mind—that belongs to *you*.'" We hope the learned serjeant does better than this when he has a concrete mortal for a client. Without going farther a-field for an answer it must be sufficient to remind him that we not only say "*my* mind," and "*your* mind," but also "*my* soul," and "*your* soul," "*my*self," and "*your*self." Who, or what is the "*Me*," which according to the profound word-argument must exist as the proprietor of the *soul* and the *self?* This very refined existence has not yet got a name; but perhaps Mr. Cox, now his attention has been called to it, will be able to tell us in his second volume (which already promises to be much more interesting than the one before us) what sort of matter it is made of, its shape, and its dwelling place.

One word more, if men will write nonsense, they might at least endeavour to write original nonsense. It is sad to think that even young ladies should have to admire the old empty sentences in every new book. S.

OUR BOOK SHELF

The Darwinian Theory and the Law of the Migration of Organisms. By Moritz Wagner; translated by J. L. Laird. (Sandford.)

AFTER the perusal of the preface to this pamphlet, the reader will expect to find that a serious objection to the Darwinian hypothesis has been detected, and that what is to follow will, by the introduction of a new law, clear up the assumed difficulty, and immortalise its discoverer. "The Law of the Migration of Organisms" of Prof. Wagner is that it is only by the isolated migration of single individuals from the station of their species, that natural selection could and can be effected, and that only by this means new varieties of plants and animals could arise in the past as well as in the present. This law is based on the considerations that the greater the change to which individuals are subjected on migration from their homes to some fresh locality, the greater will be their tendency to vary, and the less they have the opportunity of crossing with the parent stock, the more permanent will variations become. Most of the observations on which these arguments are founded have been arrived at from the author's researches on the distribution of insects and plants; and he has been led to propose it, because, as he says, "Darwin's work neither satisfactorily explains the external cause which gives the first impulse to increased individual variability, and consequently to natural selection; nor that condition which, in connection with a certain advantage in the struggle for life, renders the new characteristic indispensable."

To us it is not easy to see what direct bearing this law has on the theory of natural selection, for it seems to be nothing but one of the many deductions of Lamarck's theory of the origin of species. It is evident that on that very ingenious but equally inefficient hypothesis, the removal of individuals from their homes to some other locality in which the temperature and food are different, would cause them to vary; and that if the so modified forms are allowed again to mix with those which have not altered their position, the induced peculiarities will disappear. But, though by artificial selection an apparently similar result may be attained, yet in a wild state this is hardly the sequence of events which the evolution hypothesis supposes. According to it, the forces which come into play affect large numbers, and being generally comparable in degree and gradual in their action, those individuals which escape change in one direction are almost certain to undergo some equally considerable modification in another; consequently there will at no time be left any of the original unmodified stock for the varieties to intermix with, as required in the theory under consideration, at the same time that the effect of simple change of locality in producing new and well-marked varieties has not been conclusively proved.

From the study of the breeds of horses and cattle, Prof. M. Wagner is convinced that the invariable result of intercrossing is uniformity, and that only in connection with isolation is natural selection able to come into play. This, as do many other remarks throughout this pamphlet, shows clearly that its author does not really recognise the point of Mr. Darwin's great theory, and that whilst under the idea that he is attempting to modify it, he is really discussing another, but distantly related, and much less important problem. Such being the case, it is not surprising that the author of the theory of Natural Selection should differ from the German professor; with whom we also cannot agree in thinking that "perhaps that generous British naturalist, who is always open to conviction, after calmly weighing his reasons and data, may yet be induced to modify his opinions."

A Practical Manual of Chemical Analysis and Assaying, as applied to the Manufacture of Iron from its Ores, and to Cast Iron, Wrought Iron, and Steel as found in Commerce. By L. L. de Koninck, Dr. Sc., and E. Dietz. Edited, with notes, by Robert Mallet, F.R.S., F.G.S., M.I.C.E., &c. (London: Chapman and Hall, 1872.)

THE above little work appeared at Liège in 1871, and as it was well arranged, succinct, and clear in its descriptions, Mr. Mallet considered it worthy of translation. The plan is similar to that of Fresenius's well-known quantitative analysis, the reagents being described first, then the apparatus and operations, and then the practical application to the special class of work to which the book is devoted. On the whole we cannot help thinking that too much space is given to matter with which every person ought to be thoroughly familiar before he attempts to make a practical application of his chemical knowledge. The supercession of the skilled chemist by the "tolerably intelligent man" mentioned by the editor in his preface is not, we think, a desirable reform. The editor's notes consist of some four and twenty pages of small print at the end of the book, and they are full of valuable suggestions. His remarks on the construction and arrangement of the laboratory of an iron-work are particularly worthy of attention. The book concludes with a table of atomic weights, one for the conversion of English weights and measures, with their metrical equivalents, and one of constants for calculating percentages of substances found. The book will no doubt prove very useful in its special field.

Verhandlungen der k.-k. Zoologisch-botanischen Gesellschaft in Wien. Jahrgang, 1872, 22er Band. (Leipzig Brockhaus.)

THE annual volume of "Transactions of the Zoological and Botanical Society of Vienna" contains, as usual, a number of interesting and valuable articles. The papers are almost entirely systematic and descriptive:—On the flora of Poland (the longest paper in the volume); on birds from the shores of China and Japan; on the lichens of the Tyrol; on a collection of birds from Australia; on the bees of Germany; on North American Micro-Lepidoptera; on the oak-galls of Central Europe; and others of a similar character. Physiological or anatomical contributions occupy but a small portion of the volume, which is illustrated by seven plates.

The Art of Grafting and Budding. By Charles Baltet. (London: W. Robinson, 1873.)

THE various modes of the reproduction of plants comprised under the designations grafting, budding, layering, &c., have been more scientifically studied and carried to greater perfection by gardeners in France than in England. Baltet's "L'Art de Greffer" is the text-book on this branch of horticulture, and of this little volume we have here a translation, although the omission to note this fact on the title-page might give unwary purchasers who have not dipped into the preface the impression that it is an original work. M. Baltet is so successful a fruit-grower, and his manual is so well and favourably known, that no apology was necessary in furnishing the English reader with a translation of it, which will be an indispensable companion to all engaged in horticulture. At the end of the volume is a useful list of the more commonly grown trees and shrubs, with instructions as to the best kind of stock on which to graft them, and the method to be pursued; though it is a pity that the translator did not

take the trouble to re-arrange them in some order more intelligible to the English reader than that of the alphabetical sequence of the common French names.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Dr. Bastian's Turnip-Cheese Experiments

FROM Dr. Bastian's letter in last week's NATURE I learn that my last communication has afforded him satisfaction. The gratification which I feel at this expression of his approval is mixed with some surprise; for however confirmatory my experiments may be of his, so far as relates to the bare fact that boiling is insufficient to destroy the germinating power of the turnip-cheese liquid, they certainly do not tell in favour of the inference which he is understood to draw from that fact.

The experiments which Dr. Bastian was kind enough to show me last December were regarded by him as unequivocal instances of spontaneous generation. He will remember that at that time I stated to him, both orally and in writing, that the significance of the results in their relation to the doctrine of heterogenesis, appeared to me to be doubtful, and that I thought it probable that they would be interpreted by different persons in opposite senses, according to their preconceived opinions. I expressed myself in a similar manner at a discussion which took place on the subject last winter at the Royal Society. It was for the purpose of clearing up this doubt that I made the experiments recorded in my last communication. I did not expect to prove that the production of Bacteria in Dr. Bastian's experiments was *not* spontaneous, but merely to determine whether the fact afforded any support to the opposite conclusion.

Having first shown that living organisms increase and multiply in the liquid in question, when boiled at the ordinary temperature, under circumstances which absolutely preclude the introduction of living matter from without, I prove that under otherwise similar conditions this result is not obtained when the liquid is subjected to ebullition at a slightly higher temperature. I show further that the liquid even when heated to 102°·5 C. suffers no impairment of its power of supporting the life of Bacteria, for by inoculating it with a drop of ordinary distilled water it at once becomes pregnant. Hence I conclude, not that spontaneous generation is impossible, but that the particular experiment in question is not an instance of it, and that no argument founded on it in favour of the doctrine is of the slightest value.

It is unnecessary for me to occupy your space by at any length adverting to the side questions raised by Dr. Bastian in the other paragraphs of his letter.

In examining the liquids within a few days after heating rather than later, I followed his own method.

I made no attempt to determine the temperature of ebullition in flasks with capillary orifices, because I know of no method by which it could be done accurately. Besides, it was not required for my purpose.

I employed the word "chance" in its ordinary sense. In the sentence to which Dr. Bastian refers I explained that, although there may be a limit of temperature at which a liquid, before possessing the power of breeding Bacteria, is deprived of that power, experiments such as mine are insufficient to define that limit. As regards the turnip-cheese liquid it has been shown that between the temperatures of 100° and 102° C., the probability of pregnancy diminishes rapidly as the temperature increases. It is not as yet possible to say at what point the probability vanishes.

University College, June 30 J. BURDON SANDERSON

The Zodiacal Light

CONTRARY to Mr. Hall's experience of astronomical books (see NATURE, vol. viii. p. 7), in neither Herschel's "Outlines of Astronomy," Humboldt's "Cosmos," nor Guillemin's "Heavens," can I find any hint of a permanent difference between the brightness of the zodiacal light east of the sun and west of it, though Arago's "Popular Astronomy" says that according to Cassini, "it is generally less lively and less extended in the morning than in the evening." But even if Cassini was correct, this is no positive proof of any difference between the two "branches" of the zodiacal light at the same time, seeing that he lived in the temperate zone, and probably did not observe it in both morning and evening at the same time of year. Mr. Hall's situation in Jamaica is favourable for investigating this point, and I should not wonder if he finds the fact different from what he supposes. But even the books that consider the zodiacal light to surround the sun in the shape of a lens, acknowledge that it may extend further one way than another, and further at one time than another. T. W. BACKHOUSE

Sunderland, June 7

AT about half-past one in the morning of June 5, the sky was clear, but the stars were not very brilliant, on account of the diffused light, and consequently the Eastern branch of the Zodiacal Light was very faint; as I was endeavouring to trace its course, a strong beam of light appeared so suddenly as to have quite a startling effect; it was not shot out like the rays of the Aurora Borealis, but gathered strength throughout its whole course, which lay through Aquarius, over the stars α and β Capricorni, through Sagittarius, across the Milky Way, and through Scorpio, passing to the N. of Antares; its visible length was therefore upwards of 100°, and as I was about to make accurate observations, it suddenly disappeared, having lasted somewhat less than one minute.

Its course was therefore nearly parallel to the Ecliptic, and about 6° to the N. of it; its breadth was from 3° to 4°; its brilliancy was equal to that of the brightest part of the Milky Way, through which it passed, and therefore allowed me to judge very accurately; and it had no colour.

Now Humboldt says in his "Cosmos," * "I have occasionally been astonished, in the tropical climates of South America, to observe the variable intensity of the Zodiacal Light," and he considered the variation to be due to atmospheric changes, as I myself have hitherto done; but in the case above no ordinary atmospheric changes could have produced the effect observed.

It occurred June 4d. 18h. 40m. Greenwich mean time, and it would be very interesting to know whether the magnetic instruments were affected at any part of the earth.

Jamaica, June 1873 MAXWELL HALL

* Otté's transl., vol. i. p. 131.

Meteorological Influence of Trap Rocks

THE thermometer in a mine, or coal-pit, rises, according to Herschel, 1° for every 90 feet of descent, or 58° per mile; and, according to Clerk Maxwell, the rate of increase in this country is 1° for every 50 feet of descent. These results are obtained in passing through a very small portion of the superficial crust of the earth; such, for example, as a part of the coal formation, which possesses a very low degree of conductivity. We can hardly, indeed, conceive a worse conductor than a crust consisting of alternating strata of freestone, shale, till, coal, limestone, &c. But these strata are very frequently perforated by comparatively homogeneous intrusions in the form of trap dykes, which not only possess greater conductivity, but which, from the analogy presented by volcanoes, very probably extend down to the molten matter subjacent to the external crust of the earth. Such trap dykes may be compared to an iron poker thrust through the superficial strata having its lower end in a state of fusion, and its upper end kept cool by radiation into the atmosphere. Through any continuous dyke, if this view be correct, there will therefore be a more rapid escape of heat; and when such igneous rocks occupy spaces of many square miles of the earth's surface, one would, at first sight, expect them to play a very important part in affecting the meteorological conditions of the district in which they are found. They might be expected, by the large amount of heat which they conducted freely to the earth's surface, to stimulate the growth of plants; and by the radiation of the liberated heat into the atmosphere, they ought to become—especially during night—the generators of storms, by causing a constant ascent of rarefied air. It is quite true, however, that the meteorological effects of such an agent must, as in the case of volcanoes, be observed by the far grander cycle of disturbances initiated by the solar heat; and that its agricultural efficiency may be, to a large extent, negatived by differences of chemical constitution, acidity, and exposure. Still, however, the influence is there, and ought, in one way or other, to make itself sensible.

Do any of your readers possess information bearing upon this question? Such, for example, as experiments on the conductivity of the different kinds of trap as compared with the stratified rocks, or observations of the temperature of the air, especially during night, above trap-rocks as compared with that

of the air above surrounding districts of the coal measures, or statistics of the fertility and periods of fructification of crops under similar differences of conditions. Of course the great difficulty affecting the last point is the difference in the chemical constitution of the soils produced by the decomposition of trap and stratified rocks. THOMAS STEVENSON

Edinburgh, June 21

Winters and Summers

A FRIEND writes to me :—"From my observations of climate here (Belfast) I should say that I never saw a severe winter followed by a really fine summer. The severest winters I remember were those of 1854-5, and 1859-60. The summer of 1855 was very wet, and that of 1860 deplorable. The finest summers I remember were those of 1842, 1857, and 1868; in every case the preceding winter was very mild."

I would add to this, that the severe winters of 1865 and 1870 were not followed by remarkably fine summers. The harvest weather of 1866 was unusually bad.

Can any of your readers throw light on this subject from carefully kept registers? JOSEPH JOHN MURPHY

Old Forge, Dunmurry, June 6

Cyclones

MR. MAURY's theory of Cyclones, as stated in NATURE of the 19th. is, in my opinion, true and valuable. I hope you will permit me to call the attention of your readers to my letter in NATURE, Vol. iv. p. 305, where it will appear that I had independently arrived at the conclusion stated by him, "that the origin of cyclones is found in the tendency of the south-east trade-winds to invade the north-east trades by sweeping over the equator into our hemispheres" Only the words "south-east" and "north-east" must exchange places, and "the opposite hemisphere," must be read, instead of "our hemisphere," if we are to apply the theory to the cyclones of the Southern Indian Ocean and of the Southern Pacific. On this latter subject, see Mr. Whitmee's letter in NATURE, vol vi. p. 121.

I wish, however, to call your attention to what I think an error in the diagram of the winds, which Mr. Maury reprints from Prof. Ferrel. It represents the winds at the surface of the earth in the Polar regions as blowing in nearly the same direction as the trade winds. This appears mechanically impossible, and I cannot think that Prof. Coffin's data are extensive enough as regards the Polar regions. As the late Capt. Maury remarks, the west winds of the higher and middle latitudes constitute "an everlasting cyclone on a great scale;" that is to say, a vast vortex whereof the pole is the centre. But it appears impossible that the direction of the motion of a vortex should be reversed at its centre. JOSEPH JOHN MURPHY

Old Forge, Dunmurry, June 24

A Mirage in the Fens

As the phenomenon called Mirage is not very common in this country, though more frequent in the Fens, perhaps, than elsewhere, I presume that a description of one which was seen on Thursday, May 29, last, will be interesting to the readers of NATURE.

Driving from Wisbech towards Thorney on the morning named, I stopped at Guyhirne, and my friend, Mr. S. B. J. Skertchley, of H. M. Geological Survey, who accompanied me, mounted the parapet of the bridge of the March and Spalding Railway, to view the Fens from that elevation, and then called my attention to what appeared a beautiful lake spread out a few miles distant. The illusory waters were of a bluish grey colour, and being apparently raised from the level, presented the perspective of a Mere of considerable breadth. But this was not a dull expanse; there were variously formed indentations—islands dotted here and there, pollard willows inverted, and the reflection of tall poplars and elms on the glassy surface. The use of my field-glass only brought these features more distinctly to the eye. As we stood on the bridge, we were looking from W. by S. to W. Whittlesea Church was eight miles distant, and Thorney Abbey seven miles. The mirage was stretched out from Eastern Fen over Prior's Fen to the west of Thorney, *i.e.* three or four miles. It was 11 o'clock. There was a fresh breeze from N.E.; the sky was not half obscured by cloud; the barometer stood high, being four degrees difference between the dry and wet bulb thermometers at 9 A.M. All these conditions were favourable to evaporation; there had been more than half an inch of rain the Monday previous. Mr. S. had witnessed a similar phenomenon from another point of view (see NATURE, vol. ii. p. 337) in 1870, when he saw it both E. and W. of his position, but on Thursday last there was not even a mist in any other part of the horizon. On both occasions the wind was N.E. It may be interesting to know whether these phenomena appear with a mild and moist S.W. or W. breeze.

Wisbech, June 5 SAML. H. MILLER

The Westerly Progress of Cities

REFERRING to Mr. W. F. Barrett's letter I would remark that there is a similar phrase, viz the westerly or north-westerly progress of nations, which is intimately connected with "the westerly progress of cities," and the former helps to explain the latter. As a rule the more westerly of two peoples inhabiting a country is there by compulsion, having been driven thither by the invader who, as a rule, makes the attack from the east. The remnants of the ancient Celtic race, inhabiting portions of the western shores and highlands of Spain, France, and the British Isles, are an evidence of this. We see the same process going on now in America: the aborigines being driven before the invader, to the west. There are insignificant exceptions, both in ancient and modern times, but they only prove the rule.

So much then for the westerly among the peoples of a land: they are in the west by violent compulsion. Among the inhabitants of a city the westerly are there also by compulsion—not a compulsion by violence, but by uncomfortable pressure; in which case it is the powerful or wealthy who retire before the weaker or poorer.

The very fact of the westerly progress of nations establishes the further fact that what becomes afterwards more or less the eastern part of the city is the older and that where the first habitations were erected. An exception would be such a case as a city built on a western coast without any adjacent country to the west. Here the wealthy in retiring before their less fortunate fellow-citizens must necessarily go more or less to the east. B. G. JENKINS

London, June 9

To the instances of "westing" adduced by Mr. W. F. Barrett as occurring in the large towns of the Old World it is desirable to add that a similar tendency prevails in the large towns of the New, excepting, of course, the cases in which physical barriers impede or prevent it.

It should be observed, also, that this westward current of progress in cities appears to be but the special manifestation of a principle much more general—the direction of great emigrations and of the advance of civilisation, apparently in pre-historic and certainly throughout historical times, having been uniformly towards the west. G. J. R.

How does the Cuckoo deposit her Eggs?

A FEW days ago while examining a reed bed in the fens of Lincolnshire, near Wainfleet, I found a Reed Warbler's nest, in which was deposited a Cuckoo's egg. From the *shape* of the nest, which was very narrow and deep, and from the *position* of the nest, which was built on slender reeds, on the outer edge of the bed, it was utterly impossible that the egg could have been laid, as, in the first place, the nest was far too small for so large a bird as the cuckoo to sit in; and in the second, the weight of the bird would have inevitably swamped the nest. Does not this fact go far, at any rate, to confirm the theory held by many ornithologists to be the correct one, that the female cuckoo drops her eggs into nests by means of her bill, as it is well known she is provided by Nature with an enlargement in the throat, in which the egg could be carried in safety during her flight in search of a suitable place in which to deposit it. I give here a quotation from Bewick on the subject:—

"Naturalists are not agreed as to whether the female cuckoo lays her egg at once in the nest of another bird, or whether she lays it first on the ground, and then, seizing it with her bill, conveys it in her throat (supposed to be enlarged for this purpose) to the nest which is to be its depository."

I should be glad if any of your correspondents will inform me if the male bird has a like enlargement in the throat, or is it only to be found in the hen? T. AUDAS

Regent's Terrace, Hull

THE LATE MR. ARCHIBALD SMITH

MR. ARCHIBALD SMITH was born at Glasgow in 1813; his father, Mr. James Smith, of Jordanhill, Lanarkshire, was well known as a geologist, and as the author of a learned and critical work on the Voyage and Shipwreck of St. Paul.

At the University of Glasgow Mr. Smith was a contemporary of the late Norman McLeod and of the present Archbishop of Canterbury, with both of whom he retained a friendship through life.

From Glasgow he went to Trinity College, Cambridge, where, while still an undergraduate, he commenced to contribute papers to the Mathematical journals; his first, a most important paper "On the Equation to Fresnel's Wave Surface," is an excellent example of the extreme neatness and elegance of his style; it was published under the signature A. S. in the Cambridge Phil. Trans. and in the Phil. Magazine.

He, however, as the result well showed, did not allow his amateur mathematics to interfere with the regular course of Tripos reading, and he also found time for a good share of athletic exercise. He pulled in the Trinity boat of which the late Lord Justice Selwyn was stroke; all the oars in that boat were reading men, and were familiarly known as "Peacock's examples" (Peacock being a well-known tutor of the day). It was no doubt owing to Mr. Smith's strong physical constitution which was thus well trained in early life, that he was able so long to sustain the great strain of mental effort and the want of rest to which he never scrupled to subject himself in after years when occasion required.

In 1836 he finished his undergraduate's career by taking the first place in the mathematical tripos as well as the first Smith's prize, and he was soon after elected a Fellow of his College. The second wrangler of his year was Bishop Colenso.

Having chosen the profession of the Chancery Bar, Mr. Smith became a pupil and a friend of Mr. James Parker, afterwards Vice-Chancellor, and is said to have acquired the sound legal learning and careful method which distinguished that judge. It was during the intervals of his laborious Chancery practice that he found time for the long series of magnetic investigations which has made him famous throughout Europe.

His connection with Magnetic Science arose from intimacy with Sir Edward Sabine, the late distinguished president of the Royal Society, and who was interested in the question of the Deviation of the Compass, first as member of a committee appointed by the Admiralty to consider the question, and afterwards as having undertaken the reduction and publication of the magnetic observations made by Sir James Ross in his Antarctic voyage.

In the years 1842 to 1847 Mr. Smith, at General (then Colonel) Sabine's request, deduced from Poisson's general equations, formulæ for the correction of the observations made on board ship. These were published in successive numbers of Sabine's "Contributions to Terrestrial Magnetism," in the Transactions of the Royal Society.

In 1851, at the request of Captain Johnson, the superintendent of the Compass Department of the Royal Navy, he deduced from the formulæ the convenient tabular forms, and computed the auxiliary tables for determining the co-efficients A, B, C, D, E, which have ever since been in use. These were published by the Admiralty in successive editions, but without the demonstrations or formulæ.

In 1859 Mr. Archibald Smith edited and published the voyage of Scoresby to Australia, which was undertaken chiefly for magnetic research; and in his introduction gave, for the first time, the *exact* formulæ for the effect of the iron of a ship on the compass, the former approximate formulæ being found insufficient.

In 1862 he, conjointly with Captain Evans, the present chief of the Compass department, prepared the Admiralty Compass Manual, a book which has since been translated into French, German, Russian, and Portuguese, and gone through three editions. The work is divided into four parts, the first of which contains practical rules to enable a seaman by the process of swinging his ship to obtain a table of the deviations of the compass on each point, and then to apply the tabular corrections to the courses steered. The second part is a description of "Napier's graphic method," the practical advantages of which are that it enables the navigator from observations of deviations made on any number of courses, whether equi-distant or not, to construct a curve in which the errors of observation are as far as possible mutually compensated, and which gives him the deviation as well on the compass courses as on the correct magnetic courses. Part III. contains the practical application to this subject of mathematical formulæ derived from the fundamental equations deduced by Poisson from Coulomb's theory of magnetism. Prior to this time it was considered sufficient to use approximate formulæ, going as far only as terms involving the first powers of the co-efficients of deviation; but the very large deviations found in iron-plated ships of war rendered it desirable to use in certain cases the exact instead of the approximate formulæ, and this part was therefore re-written. The fourth part of the "Manual" contains charts of the lines of equal variation, equal dip, and equal horizontal force over the globe; the first for the purpose of enabling the navigator at sea to determine the deviation by astronomical observations, the two latter to throw light on the changes which the deviations undergo in a lengthened voyage, and to enable the navigator to anticipate the changes which will take place on a change of geographical position.

All Mr. Smith's investigations were undertaken as labours of love; but we must not leave unnoticed some of the recognitions which he received.

In the year 1865 one of the Royal medals of the Royal Society was awarded to him, and he was elected a corresponding member of the Naval Scientific Committee of Russia; in the following year the Emperor of Russia, with a most complimentary letter, presented him with a gold compass emblazoned with the Imperial arms, and set with brilliants.

Recently, too, our own Government offered him a present of 2,000*l.*, and intimated the fact to him in a handsome letter from the First Lord of the Admiralty, begging his acceptance, not by way of recompense, but as a mark of the high appreciation which the Government had for the services he had rendered.

The history of Mr. Archibald Smith's legal life is soon told. He attained the reputation of being an eminently concise and perspicuous draughtsman, and made a practice at the bar which was above the average both in extent and importance.

When Sir James Parker was made Vice-Chancellor he appointed Mr. Smith his Secretary; but the early death of Sir James brought these duties to a close. Later, a Judgeship in Queensland was offered to him, which he declined. It is said that the important change which has substituted figures for words as to dates and sums occurring in bills in Chancery was made at the suggestion of Mr. Archibald Smith.

In 1868, when the Universities of Glasgow and Aberdeen were formed into a parliamentary constituency the liberal electors chose Mr. Smith as their candidate, and they did their best, though without avail, to bring him in for the new seat.

About two years ago he was compelled by ill-health to give up work; but he had greatly rallied; and the attack which ended fatally was totally unexpected, and of but a few hours' duration. In private life those who knew Mr. Smith best admired him most; he leaves unnumbered

friends to testify to the noble simplicity of his disposition, and to the true warmth of his heart, which was always open amongst his multifarious and engrossing work.

NEW EXPERIMENTS FOR THE DETERMINATION OF THE VELOCITY OF LIGHT BY M. ALFRED CORNU

AN exact value of the velocity of light is equally interesting to astronomers and physicists. It is interesting to astronomers, for it enables us to calculate an important and not exactly known number, namely, the distance from the sun to the earth, for which cause the learned world is looking forward with so much impatience to the passage of Venus on the disc of the sun, as the observation of this phenomenon, it is hoped, will fill up this chasm. It is interesting to physicists likewise, it is evident, but especially since the remarkable researches* of Prof. Clerk-Maxwell, who has found an unexpected relation between the theories of light and electricity.

M. Alfred Cornu's experiments, to which we now call attention, have for these reasons a great interest.

The first who busied himself with this difficult question was Rœmer, a Dane, at the Observatory of Paris, where Picart had called him; but the observation of the eclipses of Jupiter's satellites, although giving a pretty good value of the velocity of light, offers, notwithstanding, some causes of error, especially the difference of brightness of Jupiter's satellites at their maximum or minimum distance from the earth; and it requires moreover an exact value of the diameter of the terrestrial orbit.

M. Fizeau (1849) showed that it was not necessary to employ astronomical phenomena, and that it was possible on the surface of the earth to make use of relatively short distances, such as four or five English miles. This rather bold experiment was much spoken of. He operated between Montmartre and Suresnes, near Paris, at a distance of about five English miles and a half.

Léon Foucault, some time after, putting into execution a project of Arago, proposed another method founded on the revolving mirror of Sir Ch. Wheatstone. The value obtained by him, 189,000 miles (298,000 kilometres) was made use of by astronomers, who deduced for the parallax of the sun a number (8″. 86), that is in concordance with the best observations of the transit of Venus.

The number obtained at first by M. Fizeau was higher, but it was given by him, who dwelt upon all the difficulties of such a measurement, with hesitation.

M. Alfred Cornu left aside Foucault's method (viz., that of the revolving mirror) which is liable to serious objections, and employed that of M. Fizeau, although he had tried the two methods of experiment at the Polytechnic School, where many physicists were able to see them.

M. Fizeau's method is free from all objection. A ray of light is sent between the teeth of a cog-wheel, and it is reflected at a great distance, so as to bring it back to the point of departure. If the revolving motion given to the wheel is sufficiently rapid, the ray on its way back meets a tooth, instead of a free passage, and does not pass through; when the speed is double, the ray meets the following interval, and passes through again, and so forth alternately for increasing rates of revolution.

Thus the returning ray alternately presents a minimum (or an extinction) and a maximum; but the speed of rotation (in order to be measured) must be kept constant during several seconds in those moments; it is one of the greatest difficulties of the experiment, for that speed is enormous. Let us add the want of precision in the evolution of a maximum or a minimum.

M. Alfred Cornu has obviated all those difficulties:—

1. By giving a speed of rotation not constant but increasing or decreasing according to a regular law, which he registers by means of electricity; so that he easily knows the speed at every moment.

2. By registering in the same manner the exact time in which the ray of light disappears and appears again: and thus he does not observe the instant of maximum or minimum, but two instants which are equally distant from the moment that is to be determined.

The various results are traced by fine needles that run on a sheet of paper covered with lamp-black, and rolled round a revolving cylinder. If the needles remain motionless, they describe a helix on the black paper, which becomes a straight line when the cylinder is unrolled. But these points are extremities of armatures of electro-magnets, and are moved when the electricity passes through; and during all the time the current passes, the traced line is above the level of the normal line.

Copy of the Automatic Registrations.

The annexed sketch shows a part of an experiment made in the month of July 1872.

The line a on the right hand side represents the increasing speed of the wheel; each time a cog of the apparatus, in its movement of rotation, touched a certain wire, the electric current had passed through, and deviated the needle for the time the cog was passing (from A to B, from C to D). During the time, from the beginning of one deviation to the other (from A to C, from C to E, from E to G), 50,000 teeth had passed. We clearly see that these intervals are decreasing, because the speed increases.

The median line indicates seconds which are sent by an electric clock.

The third line has been obtained by the observer himself by means of a Morse-key; he made the electric current pass during the time the light was invisible; P Q and R S. The sketch thus shows two extinctions and two reappearances of light. It is the beginning of the experiment.

This method, moreover, obviates one of the greatest difficulties in physical experiments, namely the noting down of various numbers, that diverts the observer and complicates operations. Furthermore, there remains not only the remembrance of the experiment made, but an exact, real, and living drawing.

M. A. Cornu has, moreover, changed the rather large and expensive apparatus of M. Froment for another,

* Everyone knows that in one of the last meetings of the British Association Sir William Thomson has estimated them at their real value.

strong and small, for it is not bigger than the fists. He uses the works of a common clock, which do not cost more than a sovereign. He has only replaced the largest wheel of the scapement by another one, lighter and more finely toothed. Special experiments, not mentioned in his present memoir enabled him to choose the most proper diameter for that cog wheel. A strong spring drives the wheel 700 or 800 revolutions in a second.

A drag has been added, in order to check the speed. By a special arrangement, the rotation of the wheel can be reversed, in order to eliminate certain errors that might result from the apparatus itself.

In order to try the improvements of the apparatus, a first series of experiments was made between the Polytechnic School and a tower of the telegraph office, at a distance of about one mile and a half (2 kilometres and a half). The observer could perceive a window of this tower amid a forest of chimneys. The distance was too short: he prudently did not publish the result.

A second series was attempted by him between the Polytechnic School and the Valérien Hill, at a distance of about six miles and a half (10 kilometres 310 metres).

But a transparent atmosphere is seldom now to be obtained in misty Paris If we go up to the garret where the observer stands, we perceive a sea of roofs below; on the right Montmartre Hill, on the left the heights of Meudon, and in the front the Valérien fortress; in one of the rooms in the barracks the mirror and the collimator were established.

The apparatus that sends forth the ray of light (an instrument with a large aperture) was laid on a solid timberwork; in front of the eyepiece is the little machine; on the left side the source of light is established, a ray of which, reflected by a glass, is sent between two teeth of the wheel.

But the Mont Valérien is concealed by mist; the window of the barrack is hardly distinguishable, although the sky is cloudless. Paris is covered with a damp and dusty veil. The sun sets behind the fortress, and suddenly the mist disappears and the air becomes transparent. The ray of light between the teeth of the wheel is to be seen in the telescope as a faint star in the midst of the inverted image of the window; it is a star of the sixth magnitude, the intensity of which increases and becomes of the first magnitude with the transparency of the air. But it is necessary to make the experiments hastily, for that transparency will not last more than one hour.*

An obstacle nearly checked the observer; the image often scintillated, and was agitated in such a manner that it was impossible to pursue the experiment. It was the warm air of a chimney unluckily standing in the way of the ray of light, the kitchen chimney of the Lycée Louis le Grand. M. Cornu waited for the holidays, and the operations were at last worked out.

He thus made more than a thousand experiments, and calculated 690 of them.

In order to determine the distance between the two stations, he compared the measures previously determined, and made himself a triangulation; the average of those numbers gave him the number above cited, about six miles and a half (10 kilometres, 310 metres).

He did not at once take the average of the numbers of his experiments, but he gave a greater value to the numbers obtained under the best circumstances. It appears evident that the results deduced from the fifth disappearance of the light are superior to those deduced from the first one, because of the more exact value of the velocity of the wheel, and that the favourable atmospheric condition rendered the disappearance and reappearances of light more plain.

The average thus obtained gives for the velocity of light 189,300 miles in a second; by dividing the number by the refractive indices of the air (1·0003) we obtain the number 189,200 miles in a second in a vacuum; the possible error in this value is about $\frac{1}{300}$.

M. Fizeau had found about 194,000 miles (312,000 kil.); Foucault 189,000 miles (298,000 kil.). The physicists will wonder at the concordance between M. Cornu's number and that of Foucault, obtained by an entirely different method; and so will the astronomers; for this number of 189,000 miles gives by calculating the value of the parallax of the sun the number 8″.86; and it is exactly the one recently obtained by M. Leverrier as a consequence of three series of observations made on the movement of planets, particularly of Mars and Venus.

If experiments on the velocity of light were made again under good topographic and atmospheric conditions, and between two stations, the distance of which would be known by a geodetic calculation, a value of this velocity would be obtained with an error less than $\frac{1}{1000}$. Astronomical methods do not easily perhaps give such an approach.

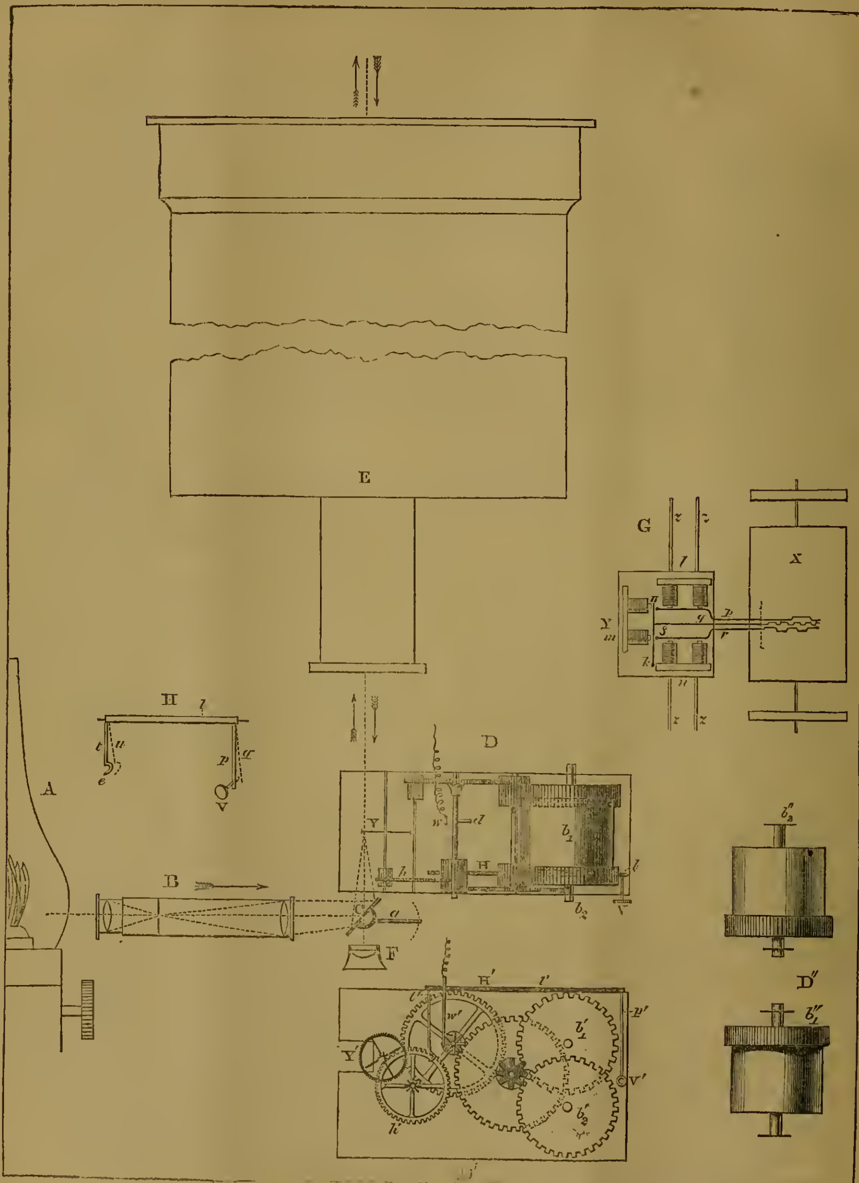
The author concludes his paper by saying: "It is to be desired for the honour of French science, that those great works relative to the velocity of light, begun by Rœmer at the observatory of Paris, pursued and simplified by some learned Frenchmen, should be finished in France with a precision worthy of their astronomical and physical importance." M. C.

Explanation of the Diagram (*see next page*).

A, Source of light; a petroleum lamp. B, a combination of lenses to direct and concentrate the light. C, D, E, F, are shown from above in order to show the direction of the ray of light:—C, glass plate, on the surface of which the light is reflected and sent into the telescope according to the direction of the arrows; *a* is a little handle which permits of small motions being given to the little plate in order to arrange it properly. D, works of a common clock drawn to the $\frac{1}{3}$ of its linear dimensions.—It is used to put in motion the cog wheel Y, between the teeth of which the ray of light is sent forth. *W*, wire touched by a cog *d* of the axis of the third wheel, at each revolution; it is united to the electro-magnet *n* (of the plate G), and thus the number of revolutions during a second is registered by *r*. b_1, b_2, two barrels that give revolving motions in a contrary direction, in order to eliminate certain errors that might result from the apparatus itself. *h*, a wheel on the side of which a drag H bears (H has been drawn apart for greater clearness); *l*, horizontal axis of rotation; V, screw; whenever by means of V the rod *p* is brought to *q*, in the same manner *l* is brought to *u*, and the extremity *e* does not rub on the side of the wheel. (Note.—A decreasing pressure is thus used, an increasing one is rendered impossible so as to prevent the delicate works from being broken.) D′, front view of the same work; the same things designed by the same letters primed. D″ shows the respective situation of the two barrels b_1 and b_2. E, telescope; the light is transmitted to a distance of six miles and a half, and comes back on the same path: the apparatus that reflects it back is a telescope like E, and performing the office of a collimator the eye-piece of which is replaced by a little mirror properly disposed. F, eye-piece of E, with which the ray of light is observed at its return; it is observed through the glass-plate C on which it has been reflected. G, apparatus by which the various data of the experiments are registered. X, lamp-blacked cylinder. Y, moveable system bearing the electro-magnets *l*, *m*, *n*. The cylinder revolves without changing its place with an uniform rotatory motion given by a special apparatus. The movable system slides by a uniform motion communicated by means of a stretching weight. The manner of giving this motion has not been represented; the relative motion is the same as if the system were immoveable, and the cylinder going forwards and revolving in the same time. *l*, *m*, *n*, electro-magnets; *p*, *q*, *r*, armatures; they terminate in needles and describe on the lamp-blacked paper the three lines drawn on the sketch. One extremity of the wire of the electro-magnets communicates with the earth, the other with a pole of a special pile; the other pole of the pile communicates also with the earth. On the way of the current that passes through from each particular pile to the three

* The source of light was Drummond's lime-light, or only a petroleum lamp. It was necessary sometimes, in the finest weathers, to moderate it, in order to have a disappearance of light more favourable to observations than a minimum of intensity.

electro-magnets *l m n*, is placed an interruptor different in each case. It registers: for *n* the law of rotation of the wheel *h* (it gives the speed of the wheel Y for each moment); for *m*, the seconds of time; they are sent by an electrical clock; for *l*, it



Cornu's Apparatus for ascertaining the Velocity of Light.

registers the time of appearances and disappearances of the light, by means of a Morse-key, on which the observer keeps his hand during the experiment. Each experiment with six, and even seven disappearances, lasts about two minutes.

ON THE FERTILISATION OF FLOWERS BY INSECTS AND ON THE RECIPROCAL ADAPTATIONS OF BOTH

DURING the last ten years, since, by his wonderful work on Orchids,* Darwin anew turned the attention of naturalists to the remarkable connection

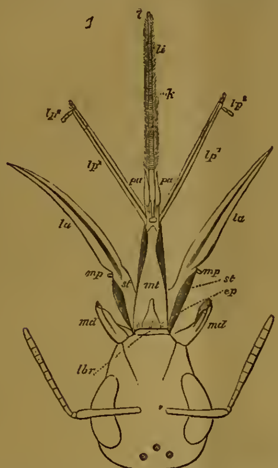


FIG. 1.—Head of a humble-bee (*Bombus muscorum* L. ♀) seen from above, with the oral apparatus stretched out to its fullest extent (5 : 1).

between the structure of flowers and the insects visiting

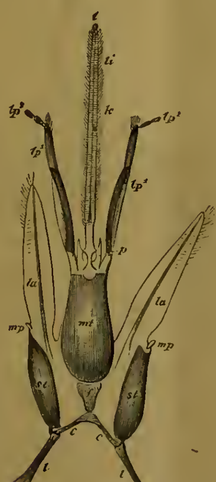

FIG. 2.—Sucking apparatus of a honey-bee seen from beneath (12 : 1)

and fertilising them, many essays on the contrivances of flowers as apparently affording facilities for intercrossing distinct individuals have been published; but there is no doubt that by far the greatest part of the work on this subject is still to be done. The most conspicuous flowers attracted, of course, in the first place, the attention of inquirers, and much greater pains was taken to show the possibility of their cross-fertilisation by insects than to observe whether self-fertilisation may possibly take place if not visited by insects. Another very obvious deficiency of observations indispensable to be made on the subject in question resulted,—the fertilisation of flowers by insects being studied by botanists but little acquainted with insects. From this cause, for the most part, when flowers were examined as to their intercrossing by insects, no complete observations were made as to the insects themselves which were supposed to visit and fertilise the flowers, and in many cases the agency of insects was over-estimated in consequence of not observing them directly.

Therefore, being myself acquainted with our flowers as well as with a great number of our insects, I thought it would be as agreeable as useful if I observed, as far as it was possible for me, the insects which really visit and fertilise our flowers, their adaptations to gain the honey

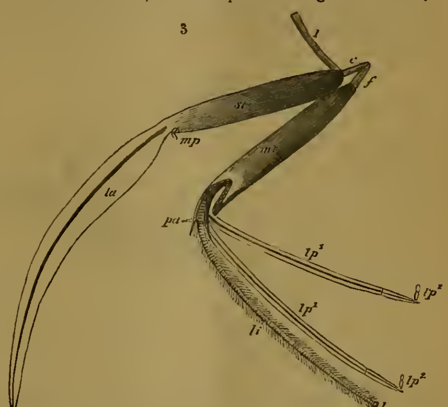

FIG. 3.—Lateral view of the sucking apparatus of a humble-bee (*Bombus silvarum* L.), representing all the four foldings partly commenced, partly imperfectly executed. A piece of the tubular mentum is broken away to show the folding of the base of the tongue (7 : 1).

and the pollen, and on the other hand, the adaptations of our flowers to the insects that visit them; and having during a series of years bestowed all my leisure upon observations of this kind, I put them together in a work which was published some months ago ("Die Befruchtung der Blumen durch Insecten und die gegenseitigen Anpassungen beider." Leipzig, 1873.) Supposing that this book is in the hands of only very few Englishmen, I think it may be of some interest for the readers of NATURE if I make them acquainted with the principal new facts contained in my work, adding some observations made since its publication.

1.—*In what manner the hive- and humble-bees obtain the honey of the flowers*

The first accurate description and drawing of the parts of the mouth of the hive-bee were given by Swammerdamm about two centuries ago, but he did not succeed in finding out the true function of the tongue; he described and drew it as perforated at the end,* and believed that it was a simple sucking pipe. His successors saw that the tongue

* "On the various Contrivances by which British and Foreign Orchids are fertilised by Insects, and on the good Effects of Intercrossing." London, 1862.

* "Joh. Swammerdamm, Bibel der Natur. Aus dem Hollandischen übersetzt." Leipzig, 1752. Taf. xvii.

of the bee is by no means perforated at the end, and that fluids, for that reason, cannot enter through its interior, but must be transported to the opening of the œsophagus by the outside of the tongue. Thus with Swammerdamm's error, that the tongue was perforated at the end, the view that it was a sucking organ was also rejected, and since then, even down to our own day, zoologists seem almost unanimously to have denied in general the sucking power of bees. Milne-Edwards calls the Hymenoptera licking insects ("Insectes lécheurs"), and says that the honey-bees nourish themselves not by sucking, but, as it were, by lapping, nearly in the same manner as a cat does ("Ainsi il n'est pas en pompant que l'Abeille se nourrit, mais pour ainsi dire en lapant à peu près comme le fait un chat"). In like manner Carl Vogt expresses his opinion on the same subject, with only the difference that he chooses for the comparison the dog instead of the cat. The bees make use of their tongue to lap, says Carl Vogt, in a somewhat similar manner as dogs apply their tongue to drink ("Sie gebrauchen ihre Zunge etwa in ähnlicher Weise zum Schlappen, wie die Hunde sich der ihrigen zum Saufen bedienen.") * Also Claus † calls the parts of the mouth of the Hymenoptera biting and licking ("beissend und leckend"), and Gerstaecker blames, in his annual report on the Progress of Entomology, Schenck for describing the tongue of the bees as serving to suck honey, whereas, according to Gerstaecker's opinion, it is only able to lick it. Hence, a good number of our best zoologists absolutely denying the sucking of bees, and our entomological works affording, indeed, very detailed descriptions of the single parts of the mouth of the bees, but not sufficiently accurate ones of the use of them, it may not be fruitless if I explain here, in some detail, the function of the oral apparatus of the bee.

If we stretch out to its fullest extent, as shown in Figs. 1 and 2, the complex machinery of the oral apparatus of a hive- or humble-bee, which, when at rest, is placed by different foldings in an excavation in the under-side of the head, so as to permit but little of it to be seen, the most prominent part we observe is the long vermicular annulated tongue (*ligula*, *li*), at the end of which a little membranous lobe is seen (*l*), the same which was erroneously thought by Swammerdamm to be perforated. The ligula is composed of a great number of rings, each of which is provided with a whorl of hairs; each whorl of hairs can be erected at will by the bee and pressed close to the ligula. The base of the ligula, which bears two appendages, the *paraglossæ* (*pa*), is inserted, together with them, in the tubular *mentum* (*mt*), and can be drawn back, as Fig. 3 shows, into the extremity of the tubular mentum, so that only the tips of the paraglossæ are

FIG. 4.—Lateral view of the suckiog apparatus of a humble-bee (*Bombus hortorum* L. ♀) in a middle sucking position (7 : 1).

visible. On both sides of the ligula we observe, also inserted in the mentum, the two four-jointed *labial palpi* (*lp*), the two first joints of which (*lp*¹), being flattened and very slender, with a central rib, form a sheath to the tongue, enclosing it from beneath, whilst the two minute joints at the tip of the labial palpi (*lp*²) serve as feelers.

When drawn back into the extremity of the tubular mentum, as is shown in Fig. 3, the tongue by no means overtops the labial palpi, but is wholly enclosed by them from beneath, whilst when pulled out as far as possible (as shown in Figs. 1, 2, and 4) it considerably overtops the labial palpi. The base of the mentum is inserted in a horny ridge, called by Kirby (in his "Monographia Apum Angliæ") the *fulcrum* (*f*). The fulcrum is placed at the conjunction of two diverging horny ridges, called by Kirby *cardines* (*c*), which connect the base of the fulcrum with the basal portion or *stipes* (*st*) of the maxillæ. The cardines can be turned round their food-points; when turned forwards, they also push forwards the fulcrum and the mentum, so as to overtop considerably the basal portion of the maxillæ (as shown Figs. 1, 2); when turned backwards, they also draw backwards the parts inserted in them, and the mentum is now enclosed by the basal portion of the maxillæ (as shown in Fig. 4). In this position the terminal portions of the two maxillæ, the *laminæ* (*la*) appearing as two flattened, lanceolate, horny pieces with a central rib, form a sheath to the tongue enclosing it from above, whilst at the same time the two first joints of the labial palpi enclose it from beneath. The *maxillary palpi* (*mp*) exist in the mouth of typical bees only as atrophied useless organs.

Besides the two foldings hitherto explained, two other foldings are to be mentioned. First, the whole apparatus hitherto described is inserted in the terminal points of two long, horny ridges enclosed in the excavation of the head and moveable round their food-points (*l*, *lora*, of Kirby). When turned forwards, the lora push forward to twice their own length the maxillæ and the mentum, with all their appendages; when turned backwards, they draw them backwards the same distance. Secondly, when all three withdrawals hitherto mentioned—(1) of the base of the tongue, (2) of the cardines, (3) of the lora—are effected, the mentum lies, defended on each side by the basal portion of the maxillæ (*st*), enclosed in the excavation of the under-side of the head; only the tongue sheathed by the laminæ and the labial palpi overtop the head, and prevent the jaws from being used; but all these overtopping parts are bent downwards and backward very easily; and now the jaws or *mandibulæ* (*md*) are not prevented from being employed.

* C. Vogt, Zool. Briefe i. p. 678.
† Grundzüge der Zoologie, 1866, p. 323.

The separate parts of the mouth of the bee and their power of moving having been considered, it remains to examine what use the bee makes of them in its different actions.

1. In order to empty the deepest honey tubes accessible to it, the bee stretches out all the moveable parts of its sucking apparatus (lora, cardines, laminæ, maxillar palpi, and tongue) in the same manner as is shown in Figs. 1 and 2, with the only difference that the two first joints of the labial palpi sheathe the tongue from beneath, and that the laminæ closely embrace the mentum and the basal part of the tongue from above. Then the terminal hairy whorls of the tongue, protruded as far as possible and advanced to the bottom of the honey-tube, being wetted with honey, the bee, turning backwards the cardines (*c*), withdraws the mentum, together with the tongue and the labial palpi, so far that the laminæ are no longer overtopped by the labial palpi, and that the laminæ and the labial palpi together, closely embracing the tongue, form a sucking-pipe, of which only the part *k-l* (Fig. 4) of the tongue is prominent. But almost at the same time the bee, folding the base of the tongue into the tubular extremity of the mentum, withdraws the terminal hairy whorls wetted with honey into the sucking-pipe, in which the honey is forthwith driven downwards to the oral opening by the erection of the whorls of hairs progressing quickly from the tip of the tongue towards its base, and simultaneously by the enlargement of the interior abdominal hollows connected with the œsophagus, which are visible from the outside by the swelling of the abdomen, and which must suck the honey towards the œsophagus.

Fig. 4 shows the head of a humble-bee in a medium sucking position. When from this position the base of the tongue is folded into the hollow extremity of the mentum (as illustrated by Fig. 3), the part *k-l* of the tongue wetted with honey is withdrawn into the sucking-pipe. Now when the lora (*l* in Fig. 4, directed downwards) are turned backwards round their food-points, the base of the sucking pipe (near *mp* Fig. 4) is withdrawn to the opening of the mouth (between the base of the two mandibulæ, *md* and the labrum, *lbr*, Fig. 4, below the epipharynx *ep*, Fig. 1), and the honey is, by pressing and sucking, driven to the œsophagus. When the lora (*l*) are again turned forwards, the whole sucking apparatus is pushed forward double the length of the lora; and now the cardines turning forward, the mentum with its appendages again advances double the length of the cardines, while the maxillæ remain at the same place, and the laminæ from this cause embrace only the mentum and the basal portion of the tongue; when at last the base of the tongue infolded in the tubular mentum is stretched out, the tongue is again protruded to its fullest extent, and the terminal whorls of hairs are again wetted with honey at the bottom of the honey-tube of the flower.

In a flower rich in honey, a humble bee may be observed executing four, five, and sometimes more, even eight or ten separate acts of suction, probably accompanied by as many protrusions of the tip of the tongue into the honey, and withdrawals of it and of the whole sucking-pipe.

I am fully convinced that the movements of the oral apparatus of the bees are as described; for by intoxicating honey- and humble-bees by chloroform, and immersing the tip of their tongue into a solution of sugar, I sometimes succeeded in seeing the movements described performed sufficiently slowly to discern each separate act very well. What occurred within the sheath of the tongue formed by the laminæ and the maxillary palpi, was of course not visible, but bending them aside after wetting the tip of the tongue with the solution of sugar, I sometimes saw the erection of the whorls of hairs progressing from the tip towards the base of the tongue.

Hence undoubtedly the statement of zoologists, who, absolutely denying the sucking power of bees, assert that they lick or lap the honey in a manner similar to a dog or a cat when drinking, must be essentially modified. The terminal whorls of hairs are filled with honey by adhesion; this honey withdrawn into the sheath of the tongue is driven towards the œsophagus by a double cause, first by the pressure of the erect whorls of hairs, and secondly by suction. HERMANN MÜLLER

(*To be continued*)

*ON SOME REMARKABLE FORMS OF ANIMAL LIFE FROM GREAT DEEPS OFF THE NORWEGIAN COAST**

THE name of George Ossian Sars is honourably connected with a very interesting chapter in the history of deep-sea research. As early as 1850, his illustrious father, Dr. Michael Sars, had challenged Edward Forbes's conclusions respecting the bathymetrical terminus of animal life. He remarked,† that at least in the Norwegian Seas, it appeared to extend much beyond the limit which the English naturalist had fixed for it. Forbes had not dredged below 230 fathoms, and at this depth he had only obtained two living Mollusca and a couple of Serpulæ; hence he was led to place the zero of animal life at 300 fathoms. Sars, on the contrary, even at the early period just mentioned, had obtained from a depth of 300 fathoms a number of animals, including a species of Coral, Molluscs, Polyzoa, &c.; and he sagaciously remarked that there was evidence of the existence of a *vigorous* animal life at this great depth, inasmuch as some of the species (*e.g. Terabratula septigera* and *Lima excavata*) were the largest known representatives of their respective genera. In confirmation of his opinion, he was able to offer, in 1864, a Catalogue of 92 animals, which had been obtained in depths varying from 200 to 300 fathoms. More recently his son has devoted himself with much energy and success to deep-sea investigation, and in 1868 had extended his dredgings to 450 fathoms, and added no less than 335 species to those already published. He says:—"I found to my great surprise at this enormous depth, not . . . a poor and oppressed Fauna, but on the contrary a richly developed and varied animal life. . . . And so far was I from observing any sign of diminished intensity in this animal life at increased depths that it seemed, on the contrary, as if there was just beginning to appear a rich and in many respects peculiar deep-sea fauna, of which only a very incomplete notion had previously existed." Amongst the new forms thus obtained was the famous *Rhizocrinus Lofotensis*, descended from Oolitic ancestry, which furnished, according to Dr. Carpenter, "a principal 'motive'" of the *Lightning* expedition. It is interesting to learn that these productive dredgings at the great depth of 200-450 fathoms were accomplished in an ordinary fishing-boat with a crew of three men.

In the important paper which forms the subject of the present notice, Mr. G. O. Sars has given us an account of some of the results of his dredgings in the "great deeps" off the Coast of Norway, founded partly on the posthumous manuscripts of the late Prof. Sars, and partly on his own investigations. Various new species of Mollusca, Annelids, Corals, and Sponges, all of them dwellers in depths varying from 100 to about 500 fathoms, are described, and illustrated by excellent figures. But that which gives a peculiar and distinctive interest to the work is the elaborate memoir on a remarkable Polyzoon, taken in the year 1866, from a depth of 120 fathoms, at Skraaven, in Lofoten. This unique animal is not only

* Partly from posthumous manuscripts of the late Prof. Dr. Michael Sars By George Ossian Sars.

† "Beretningom en i Sommerenn, 1849, foretagen Zoologisk Reise i Lofoten og Finmarken," p. 13.

generically distinct from all the forms that had been recognised at the time of its discovery, but must be referred to a new Order or Sub-class: it is chiefly interesting, however, to the biologist from the light which it throws on the history and affinities of the tribe to which it belongs. Its occurrence was first recorded in 1868 by the elder Sars, who gave it the name of *Halilophus mirabilis*, but did not at that time enter upon the details of its structure. In 1869 Allman described a new Polyzoon, under the name of *Rhabdopleura Normanni*, which had been dredged up from deep water in Shetland, and which presented some remarkable peculiarities. Its polypides (according to Allman) were of the Hippocrepian type, having the tentacles disposed in the form of a horse-shoe, instead of circularly, an arrangement which had only been noticed so far amongst the fresh-water division of the Polyzoa. Another anomalous character was the presence of a rigid, chitinous rod, extending throughout the creeping portions of the polyzoarium, to which the polypides were attached at intervals by means of a long flexible cord. It now appears that the Shetland Polyzoon belongs to the same genus as the Lofoten form just mentioned. Allman, however, having only access to specimens preserved in spirit, was unable to master all the details of the structure or to apprehend fully the significance of the organism as a whole. For a complete knowledge of *Rhabdopleura* we are indebted to the careful observations of the younger Sars, who studied the living animal; while to his father we owe a most interesting interpretation of the facts which the son had established.

Without entering into minutiæ, I shall endeavour to describe briefly the characteristics which mark out the *Rhabdopleura* as unique, and invest it with so high an interest, not only for the student of the Polyzoa, but also for the philosophical biologist. In the first place, it may be stated broadly that we find in this form the Polyzoan type in a rudimentary and half-developed condition. It clearly represents a very early stage in its evolution, if evolution be the method of Nature. The points which separate it most strikingly from its congeners are not the equivalent of the ordinary differences that occur amongst the members of the same class; they might rather be regarded as surviving features of another and very different type, from which it has diverged, and are strictly transitional in character. *Rhabdopleura* is a Polyzoon, and yet not *all* Polyzoon. A large portion of its structure, while clearly taking the Polyzoan direction, differs widely from that of all known Polyzoa. Some of the features which we should regard as most characteristic of this class are altogether wanting. And organs in which the Polyzoan type is most distinctly traceable, appear in a simpler and more rudimentary condition than in any other known form. In a word, two types of structure seem to blend in this remarkable animal, one, as it were, fading away, and the other dawning.

The polyzoarium in *Rhabdopleura* bears a striking resemblance to that of a Hydroid, and might belong to a *Coryne* or *Eudendrium*. It consists of a number of erect, chitinous tubes, distinctly annulated, which are united by a creeping, tubular stem. Each of the erect tubes (zoœcia) contains a polypide, and every polypide is attached by a contractile cord to a dark-coloured, cylindrical rod, which pervades the creeping portion of the polyzoary. The polypide differs from those of the normal Polyzoa in the following important particulars:—

1. It is without any sort of attachment to its cell, in which it lies quite free. In all other known Polyzoa a membrane (the endocyst) lines the cavity of the cell, and envelopes the polypide, to which it is attached above, at the base of the tentacular crown. When the animal retreats into its cell, it draws in with it the anterior portion of this membrane, which securely closes the aperture. Between the endocyst and the body of the polypide is a space (the perigastric cavity), in which the nutritive fluid is confined. But in *Rhabdopleura* the endocyst is altogether absent, or appears in a perfectly elementary condition, as a "thin, glassy skin," immediately surrounding the digestive apparatus. There is nothing to close the orifice of the cell, and the surrounding water passes freely into its interior. There is no perigastric cavity or fluid. The polypide is as free and unattached as a Hydroid in its calycle; and its only connection with the colony is through the contractile cord already referred to.

2. The digestive system is of the Polyzoan type, but of much lower grade than is found elsewhere. There is little specialisation of parts; the stomach and intestine consist of a simple tube, wider towards its upper extremity and narrowing off rapidly towards the posterior end, which is bent abruptly upon itself. The intestine is not separated from the true stomach by any valve, but is an immediate continuation of it, and passes off from its lower extremity in a straight line to the anal orifice.

In the normal Polyzoa, on the contrary, the stomach is divided into two well-defined regions; and the intestine, which is marked off by a distinct valve, takes the origin between the upper portion and the large, sub-globular sac, in which it terminates below. We have in *Rhabdopleura* the bent tube and the two orifices (oral and anal), but beyond this, perfect simplicity of structure.

3. The tentacular apparatus exhibits some remarkable features. It differs essentially from that of the marine, and also from that of the fresh-water Polyzoa, though it most nearly approaches the latter. It consists of two symmetrical lobes or arms, which extend out dorsally from the anterior part of the body, diverging to each side; and each of which bears a double row of ciliated tentacles. These lobes are very flexible, and exhibit great mobility, bending slowly in various directions; and in this respect they contrast strikingly with the unchanging lophophore of the fresh-water Polyzoa. The single tentacular crown, which belongs to all the other known members of the class has here disappeared; and instead of the circular verticil of the marine, and the crescentic but continuous series of the fresh-water species, we have here two series, borne on distinct flexible and movable appendages.

4. In *Rhabdopleura*, the complicated muscular system concerned in the protrusion and retraction of the polypide, which is so characteristic of the Polyzoa, and on which their lively and rapid movements depend, is suppressed along with the endocyst. *Retraction* is effected solely by means of the cord that passes from the body to the rod pervading the creeping stem. It is a very slow and sluggish process, the polypide exhibiting none of the sensitiveness and vivacity of its kindred. Under extreme provocation it retires very deliberately; an ordinary Polyzoon disappears with the speed of light, on the slightest alarm. This sluggishness, as our author remarks, is accounted for "by the want of special retractor-muscles, and by the slightly developed contractile elements, not distinguishable as evident muscular fibres, in the contractile cord."

Still more remarkable is the mode in which the protrusion of the polypide is effected. In the absence of the usual muscular appliances, it is difficult, at first sight, to imagine how the creature can raise itself from the lower extremity to the aperture of its tubular dwelling. It appears, however, that a special and most singular organ exists for the purpose, and that here also the *Rhabdopleura* departs altogether from the customs of its race. This organ consists of a large and prominent shield or disc, which projects from the anterior end of the body between the oral and anal orifices, and is thickly covered with cilia. It evidently corresponds with an anomalous structure (known as the *epistome*), which occurs only amongst the freshwater Polyzoa, and the function of

which has not hitherto been determined. Sars has observed that this ciliated disc is closely appressed to the wall of the cell, during the process of protrusion, and is in fact a kind of foot or creeping-organ, by means of which the polypide laboriously draws itself up towards the aperture of its tube. The Polyzoon, which, in its normal condition, is equipped with a powerful muscular apparatus, and remarkable for its vivacious habits, here literally crawls out of its cell.

5. It only remains to notice the dark-coloured cord, which runs throughout the creeping stem, and is a very marked feature of this curious form. It is described as a cylindrical tube, with firm, horny walls, inclosing a soft, transparent, cellular substance, from which branches are given off at intervals, and enter into the contractile cord of each polypide. This "axial cord" may no doubt be compared with the so-called nerve-trunk pervading the stem of other marine Polyzoa—the principal element of the supposed colonial nervous-system. Our author rightly regards the soft substance extending through the cord, as a sort of incompletely defined nervous trunk connecting all the individuals of the colony.

Of the development of *Rhabdopleura* little can be said at present. Both Sars and Allman, indeed, have recorded observations made on the formation of buds; but they disagree in their interpretation of several important points; and we must wait for further information before we can master this portion of the history.

From the foregoing account it is evident, as stated at first, that in *Rhabdopleura* we have the polyzoan structure in a very rudimentary condition, and half disguised by features that are alien to it as it now exists; some of its principal elements are fully established, though in a simpler form than we find them elsewhere; some are altogether wanting; while one important class of functions (the various movements of the polypide) is provided for by means which have no parallel whatever amongst other members of the tribe, and in part by an organ, which survives, reduced in size and with a different office, in one section only, as the so-called *epistome* of the fresh-water species.

Allman's examination of the Shetland *Rhabdopleura*, as preserved in spirits, led him to regard the Polyzoa as connected with the Mollusca, through the Lamellibranchiata, rather than the Brachiopods. Prof. Sars, relying on his son's investigations, takes a very different view of their affinities. He regards the *Rhabdopleura* as an organism "which stands as it were in the middle between the Hydrozoa and the Polyzoa," and forms a transition from one to the other. It is undoubtedly, he says, "like many other animals which at present inhabit the greater depths of the sea, . . . *a very old form*, which in its organisation has still retained several features from the time when the animal type that we call Polyzoa first developed itself from a lower type." He considers it to prove that the Polyzoa "are most closely related to the type of the *Cœlenterates*, and especially to the class *Hydrozoa*," from which they are probably derived.

It is my present object merely to report results, and not to offer any criticism upon them; but it may safely be said that the paper, a portion of which I have summarised, is one of the most interesting and important contributions to biological literature, that have lately appeared.

It is right to add that the author, considering "one of the great universal languages" preferable to his mother-tongue, as the vehicle of scientific research; and as a graceful acknowledgment of the services rendered by our countrymen in recent times to zoological science, has courageously, and to the relief of many of his readers, written his memoir in English.

THOMAS HINCKS

NOTES

AT the Midsummer Commencements, held last week in Trinity College, Dublin, the honorary degree of LL.D. was conferred by the University of Dublin on Dr. Andrews, of Belfast, and Professor Wright, of Cambridge.

DR. JAMES MURIE, Professor of Anatomy in the Edinburgh Veterinary College, has been elected to the newly-founded lectureship of Animal Physiology in the Edinburgh School of Arts.

ARCHÆOLOGISTS will be interested, and no doubt pleased, to hear, that Sir John Lubbock has just bought Silbury Hill, the grandest tumulus in Great Britain, if not in Europe.

WE have a number of earthquakes to chronicle this week; that in India, it will be noticed, preceded only by a day those of Italy. The earthquakes in Chili, on the 15th May, were of a very serious character. They affected Valparaiso, Santiago, Quillota, La Ligua, Canquenes, and Salvados. At Chillan, Concepcion, and Talchuano, in the south, so far as we can understand, it was slight. At Valparaiso, it commenced at 12.32 P.M., and lasted forty-two seconds, with a vertical motion, so that the ground danced under foot. Two churches and many buildings were damaged. Gas branches were wrenched from the ceilings, and books thrown from the shelves. In Salvados, in Central America, the earthquakes had ceased in May. At 2 P.M. on the 28th June, Asseerghur Fort was visited by an earthquake which lasted for about three or four seconds, direction from north-west to south-east. On the morning of June 29, about five o'clock, an earthquake visited several parts of Italy. At Verona, Treviso, and Venice, though the shocks were severe, little damage was done; but at Feletto, north of Piane, and near Conegliano, the church fell in and thirty-eight people are reported to have been killed. At Belluno four persons were killed and several wounded. At Picve del Alpago several persons were injured. Two persons were killed at Torres, four at Curago, eleven at Puos, two at Visione, and one at Cavessago.

WE regret to hear that difficulties have arisen in the management of the Brighton Aquarium, which are likely to lead to the resignation of Mr. Saville Kent, who lately vacated a post in the British Museum for that of Curator and Resident Naturalist to the Aquarium. Of the nature of the dispute we are not informed, but it seems unfortunate if some means may not still be found by which an amicable arrangement may be arrived at between Mr. Kent and his colleagues by which his services may be retained to the institution.

THE female Octopus at the Brighton Aquarium still continues to guard her clusters of ova with the greatest vigilance, refreshing them at short intervals by turning upon them a powerful stream by means of her tubular funnel; no increase to the number deposited having taken place since last week, the usual complement produced may be presumed to have been excluded. The truncate "*Hectocotylus*" arm of the male, in this instance the third on the left side, is fast recovering its normal condition, a new slender filamentous process has sprung from the ruptured extremity, resembling, in detail, the reproduced arm of an *Ophiocoma* or Brittle Starfish. Mr. Saville Kent is of the opinion that the *Octopus tuberculatus* of D'Orbigny will prove on closer investigation to be the mate of *O. vulgaris*; the difference in appearance between individuals of the same species but the opposite sex being most marked when once recognised; the general surface of the integument in the female is comparatively smooth, while numerous rugosities and elevated papillæ adorn that of the male, more particularly in the neighbourhood of the head.

It has been announced by cable from America that a new planet (No. 132) was discovered by Prof. Henry on June 13.

The just published lecture, delivered in April last by Prof. Flower at the Royal Institution, on "Palæontological Evidence of Gradual Modification of Animal Forms," is accompanied by an excellent and very ingeniously-constructed diagram of the affinities of the different members of the class Ungulata, including all the fossil as well as the recent forms. Each genus is represented by a circle, the comparative size of which indicates the number of species included in it. The existing genera are left white, and those which have fossil representatives are surrounded by rings, which are so shaded as to make it easy by referring to an accompanying table, to find in which stratum the form first appears; the extinct genera appear as shaded circles. Consequently the Peccary and Babirussa are represented by unsurrounded white circles, while *Coryphodon* and *Lophiodon* are all shaded; *Antilope* is a large white circle surrounded by a late Miocene ring; *Accraterium* has a central late Miocene circle and an early Miocene ring, indicating its range in time. Such a method applied to all the classes of animals, if equally thorough and accurate, would be an invaluable acquisition to Zoological Science.

The following telegram dated Alexandria, June 30, 1873, 1 P.M., has been received at the Foreign Office, from the Hon. H. C. Vivian, Her Majesty's Acting Agent and Consul-General in Egypt:—"Telegram just received from Sir Samuel Baker, dated Khartoum, yesterday, reports his safe arrival there in good health, with all the other Europeans. The country as far as Equator annexed to Egyptian dominion. All rebellions, intrigues, and slave trade completely put down. Country orderly. Government perfectly organised, and road open as far as Zanzibar. El Zaraf navigable. Victory on June 8 with only 105 men, over army of Onioso. This mission completely successful."

M. de Lesseps is a candidate for the place in the French Academy vacant by the death of the late M. de Verneuil.

The name *Drepanephorus* having been recently used by Sir Philip Egerton for a species of fossil fishes, Mr. Sclater proposes to change the generic name which he gave to the Paradise Bird discovered by the Italian naturalist D'Albertis, to *Drepanornis*. We shall shortly have the opportunity of offering to our readers a description of this bird from the hand of Mr. Sclater, together with a drawing illustrating its peculiarities.

Some years ago, in connection with the Berlin Geographical Society, an Association, joined in by all the chief European powers except France and England, was formed for the purpose of determining a standard European metre, to be based on the exact determination of the meridian between Christiana and Palermo. The work has developed itself into the ascertainment of the dimensions of the globe, and the Association has been now joined by France, England thus being the only power which holds itself aloof from taking part in the highly valuable work. The result will be the union of the triangulation of the whole of Europe.

At the recent D.Sc. examination of the University of London Mr. Richard Wormell, M.A., passed in Electricity, and Mr. Augustus C. Maybury in Geology.

Attention has been lately given by the American Ethnologists to the fossil skeleton of Guadeloupe, and they support the suggestion that it belongs to the Carib race. This admission still allows of considerable antiquity.

Doctor Don Ricardo de la Parra, died at Envijado, in Antiouquia, U.S. of Colombia, on May 9. He was about to publish a work on Elephantiasis, which had been a special study.

The volcano of Puraca, in the western state of Cauca, in the U.S. of Colombia, has been in convulsion for three years, and is now causing great alarm. It gives rise to frequent storms.

The forthcoming number of Petermann's *Mittheilungen* will contain a very interesting article by Carl Dambeck on the Geographical Distribution of Sea-fish, in which the author divides the ocean into eleven regions, and gives lists of the principal fishes to be found in each region.

Mr. Lamont's fine yacht *Diana*, which was chartered by Mr. Leigh Smith, and which recently left Dundee on a Polar Expedition, is reported by the whaler *Eclipse*, which arrived at Peterhead on Sunday. The letters which have been received announce that the party were on June 1 last in latitude 77·40, being among the floating ice, which reached northward to Spitzbergen. At that time all connected with the expedition were well, and notwithstanding that very severe weather had prevailed since leaving Scotland, no accident had happened. The arrangements had been slightly interfered with in consequence of the tempestuous weather, and the island of Jan Mayen had not been reached. The *Diana* was to proceed along the outside of the ice towards the north-west corner of Spitzbergen, where she will meet a storeship which preceded her.

Much gratification is felt in Peru at the discovery of a new coal deposit near Pisco, which is said to be one of the best and richest on the Pacific coast, and the locomotives on the Ica and Pisco Railway are using it with great success. The mine is situated close to the sea, and near a perfectly safe harbour, and the coal is said to be finer in quality than any in Chili, and of great extent, and, if so, must prove to be of very great economical value.

A general meeting of the members of the Aëronautical Society of Great Britain was held on Monday evening in the theatre of the Society of Arts, under the presidency of Mr. Glaisher. A number of models prepared for the occasion were exhibited by persons actively interested in the advancement of the great scheme of aërial navigation. The chairman, in his opening remarks, expressed his satisfaction at having to record several marks of progress made during the past year in the science in which they were all so interested. These marks were certainly slight, but they were nevertheless decided steps in the right direction. Very many experiments of the highest importance to the furtherance of aërial navigation had been carried out in many cases with what might be considered tolerably satisfactory results. The Society had, he added, expended a sum of 1,200*l*. in the construction of a balloon the motive power of which was to be brought about by a small steam-engine, now in preparation, of a merely nominal weight, and giving, for its size, an exceedingly high pressure of steam. A model of this was exhibited in operation by Messrs. Thomas Moy and R. E. Shill. Papers were read during the evening by several gentlemen, including Mr. Bennett and Mr. D. S. Brown.

The French "Society of the Friends of Science," an association for succouring the widows and orphans of men of science, has distributed during the last three years, in spite of the misfortunes of the country, 88,439 fr.

The scarcity of rags has, it is well known, recently induced paper manufacturers to look out for new textures as substitutes for those formerly used. In France hop-stalks have been successfully utilised for this purpose, and in this country an attempt has been made to utilise jute for newspapers. A copy of the *Warrington Guardian*, printed on jute paper, has been sent us, and it appears to us quite satisfactory.

A Society for the Promotion of Scientific Industry has recently been established in Manchester. Its object is the increase of the

technical knowledge and skill of those engaged in the various industries, the improvement and advancement of manufactures and the industrial arts and sciences, and the general progress, extension, and well-being of industry and trade. The society is sending out artisans to Vienna to profit by the Exhibition now being held there, as was done by the Society of Arts on the occasion of the Paris Exhibition, and it proposes to hold in the autumn an exhibition of designs in textile fabrics and of fuel economisers.

A PAPER entitled "Contributions to a Knowledge of North American Moths," by Aug. R. Grote, was read on June 6 before the Buffalo (U.S.) Society of Natural Sciences, in which it was stated that three new genera (Litognatha, Meghypena, Phæcasiophora), and nineteen hitherto undescribed species (Acronycta, 4; Agrotis, 1; Cloantha, 2; Litognatha, 2; Meghypena, 2; Botis, 1; Phæcasiophora, 1; Eurycreon, 1; Peuthina, 3; Grapholitha, 1; Oeta, 1) occur in the North American insect fauna. At the same time a paper entitled "Descriptions of New Species of Fungi," by Chas. H. Peck, was read, in which it was stated that 142 hitherto undescribed species of fungi (Hymenomycetis, 96; Gasteromycetes, 11; Coniomycetes, 18; Hyphomycetes, 6; Ascomycetes, 11) occur in the flora of the United States.

IN connection with the Social Science Congress, to be held at Norwich, from the 1st to the 8th of October next, there will be an Exhibition of Educational, Sanitary, and Domestic Appliances, based on the experiment which proved so successful at Leeds in 1871. The object of the exhibition is to bring under the notice of the public generally, and particularly those who are interested in social, sanitary, and educational questions, the latest scientific appliances for improving the public health and promoting education. The exhibition will be open to exhibitors from all parts, and the management will be under the superintendence of a committee.

A VALUABLE paper in the May number of the *Canadian Journal* is a contribution to a Fauna Canadensis, by Prof. H. Alleyne Nicholson, being an account of the animals dredged in Lake Ontario in 1872. The dredgings were all carried on within a radius of ten miles from Toronto, and Prof. Nicholson describes the nature of the bottom, and forty-three species of animals taken up in the dredge, belonging to Annelida, Crustacea, Arachnida, Insecta, Mollusca, and Vertebrata. The paper possesses several points of interest.

WE have received Nos. 3 and 4 of the *School Laboratory of Physical Science*, a small quarterly journal edited by Prof. Hinrichs, Director of the Laboratory of the Iowa State University. The longest paper is entitled "Science in Schools," and gives a comparative view of the place occupied by Physical Science in the Classical Courses of the American Colleges, the palm in this respect being given to Harvard. Prof. Hinrichs thinks, notwithstanding the comparatively great importance attached to physical science in America, the place allotted to it in her universities is still far from satisfactory. Under the head of "Laboratory Notes," Prof. Hinrichs gives a method of determining the Velocity of Sound in the Atmosphere.

MR. T. LOGIN, C.E., Superintending Engineer, 2nd Circle, Punjab, has sent us a small pamphlet, entitled "Practical Notes on the Egyptian Mode of Cotton Cultivation," containing a series of well-arranged directions on this subject, founded on Mr. Login's own experiments, which appear to have been unusually successful.

WE have received from Messrs. Asher and Co., Nos. 378, 379, 380, of Kirchoff and Wigand's (of Leipzig) "Antiquarisches Bücherlager," containing long lists of very valuable works in Mathematical, Physical, and Mechanical Sciences.

ACCORDING to the *American Artisan*, the new educational system in Japan embraces the organisation of 8 colleges, 256 high schools, and over 50,000 public schools, at which the attendance is to be compulsory for all children above six years of age.

A SUPPLEMENT to the Fifth Annual Report of the United States Geological Survey of 1871, contains an enumeration with descriptions by Mr. Leo Lesquereux, of some tertiary fossil plants, from specimens procured in the explorations of Dr. F. V. Hayden, in 1870. Another small pamphlet connected with the same survey contains carefully compiled and very valuable lists of elevations and distances in that portion of the United States west of the Mississippi, collated and arranged by Prof. C. Thomas.

THE "Report of the Entomological Society of Ontario," for 1872, contains papers on Insects injurious to the Grape, the Strawberry, the Hop, the Maple, the Peach, the Potato, on some innoxious insects, and on beneficial insects.

WE have received the "Report of Progress" of the Geological Survey of Canada for 1871-72, containing detailed and well-compiled accounts from the various parties who are carrying on the work.

WE learn that there has been erected a small observatory on the Columbia (U.S.) College campus for educational and, we hope, also for scientific purposes. The observatory is furnished with an equatorial, accompanied by a seven-prism spectroscope, by Clark, and a position micrometer, besides an altazimuth and a zenith telescope.

WE take the following from a paragraph entitled "Prof. Agassiz on Natural History in Schools," in the *University Monthly* (New York):—"I am satisfied that there are branches of knowledge which are better taught without books than with them; and there are some cases so obvious, that I wonder why it is that teachers always resort to books when they would teach some new branch in their schools. When we would study natural history, instead of books let us take specimens—stones, minerals, crystals. When we would study plants, let us go to the plants themselves, and not to books describing them. When we would study animals, let us observe animals."

ADDITIONS to the Brighton Aquarium during the past week; 2 Bass (*Labrax lupus*); 14 Black Bream (*Cantharus lineatus*); 1 Ballan Wrasse (*Labrus maculatus*); 1 three-bearded Rockling (*Motella vulgaris*); 6 Sea Crayfish (*Palinurus vulgaris*); 1 Toad Crab (*Dromia vulgaris*), 1 Octopus (*Octopus vulgaris*), presented by Mr. C. J. Small, of Hastings; 1 Sea-hare (*Aplysia punctata*); Oysters (*Ostrea edulis*); Mussels (*Mytilus edulis*); Zoophytes (*Tealia crassicornis*, *Alcyonium digitatum*).

THE additions to the Zoological Society's Gardens, during the last week, include an Erxleben's Monkey (*Cercopithecus erxlebeni*); a Moustache Monkey (*C. cephus*); a banded Ichneumon (*Herpestes fasciatus*) and two bronze Spotted Doves (*Chalcopelia chalcospilos*), from West Africa, presented by Mr. J. J. Monteiro; a greater Sulphur Crested Cockatoo (*Cacatua galerita*), from Australia, presented by Mrs. Thomas; a Hyacinth Porphyrio (*Porphyrio hyacinthinus*), from West Africa, presented by Lady Cust; a grey Ichneumon (*Herpestes griseus*), from India, presented by Mr. W. Walker; an Argus Pheasant (*Argus giganteus*), from Malacca; two Rufous-tailed Pheasants (*Ceriornis erythrophthalmus*), from India; a white-handed Gibbon (*Hylobates lar*), from the Malay Peninsula; a Puma (*Felis concolor*), from Bogota; two Lanner Falcons (*Falco lanarius*), from E. Europe, deposited.

SCIENTIFIC SERIALS

Der Naturforscher, May.—This serial, containing little that is original, furnishes a weekly supply of well-selected and adapted matter from various sources. In the present number attention may be called to an academical address delivered by Herr Streng at Giessen, on the "circle-course" of substances in nature, treating chiefly of geological phenomena; to an account of Herr Janettaz's recent careful researches on the conduction of heat in crystals (some 44 mineral species having been examined); to a theoretical investigation by Herr Handl (Vienna Academy) of the conditions of saturated and supersaturated solutions, and to several papers of meteorological experiment: on moisture in forests and in the open, on the temperature of rain, and on the velocity of winds as measured on various heights on Antwerp Cathedral.—Some observations of M. Du Breuil on the partial decortication of horse-chestnuts, are worthy of notice. He found about twenty of these trees in the park at Compiègne, the bark of which had been eaten off twenty-four years previously, by rabbits, to a height of 30 or 40 centimetres. From several experiments he concluded that the chestnuts could live thus long without communication with the soil, and that the elements necessary to their growth were obtained partly from the atmosphere, partly through endosmose from the woody tissue formed before decortication.—Among several French Academy papers are those by M. Jamin on the laws of the normal magnet, and M. Faye on circulation of hydrogen in the sun.—English and American science is also represented.—A curious fact is stated in the "Kleinere Mittheilungen": Herr Eimer has recently found, on a precipitous rock near the island of Capri, a new species of lizard. It is blue all over, with dark spots on the back; while the lizards in Capri are of a bright green, with only a little blue at the extremities. Now the rock (which is frequented by birds of prey) has little or no vegetation, and its natural colour is a bluish grey, or dark blue in the shaded parts. The lizard, when at rest, can hardly be detected by sight, its colour is so like that of the rock. Herr Eimer finds indications that the rock was once connected with the land, and supposes green lizards to have gone over and been gradually transformed to blue, through natural selection.

THE *American Journal of Science and Arts* for June commences with a biographical notice of Dr. John Torrey, the botanist, who died in March last, in the 77th year of his age.—Mr. G. J. Brush contributes a paper on the analysis of an Anglesite from Arizona, worked out in the Sheffield Laboratory of Yale College.—Prof. Dana discusses some results of the earth's contraction from cooling, including the origin of mountains and the nature of the earth's interior.—Prof. J. H. Eaton has a paper on the relations of the sandstone, conglomerates, and limestone of Sauk County, Wisconsin, to each other and to the Azoic.—Prof. Le Conte replies to Mr. T. S. Hunt's criticisms on his paper on the formation of the great features of the earth's surface.—Mr. Verrill remarks on Mr. Jeffrey's article on "The Mollusca of Europe compared with those of Eastern North America," in which, while differing from that author, who thinks that most of the New World forms are derived from the old, he considers the reverse is the case.—Prof. Young proposes the use of diffraction "gratings" as a substitute for the trains of prisms in a solar spectroscope; and he considers that they might well supersede prisms on account of their lightness and ease in management. Prof. Marsh gives further notices of Tertiary mammals, describing two new genera, *Tillotherium* and *Brontotherium*, allied respectively to *Anchippodus* and *Titanotherium*.

Bulletin Mensuel de la Société d'Acclimatation de Paris.—The April number of this serial has only just come to hand. It gives details of all the prizes in the gift of the Society for papers or works on matters in which it is specially interested, or for success in carrying out its objects in the acclimatisation or improvement of various animals or plants. No less than 88 prizes, of the money value of more than 75,000 fr. (3,000*l*.), remain to be competed for, besides 31 medals. By this means the Society does much to popularise the work it has in hand, and to make known the experience gained by those who have interested themselves in it. The system of lending specimens, on condition of receiving, for further distribution, a certain part of the produce, is explained in a paper by M. Passy, the vice-president. It appears that Algeria and Madeira, Guadeloupe and Martinique, besides Switzerland, Russia, Italy, Austria, and some other European countries, are brought within the field of the Society by means of branches, or affiliated societies of a similar nature.—A paper entitled "Le Jardin de mon Grandpère," by Edmond About, the George Augustus Sala of French literature, gives some idea of the benefits conferred by careful cultivation. "To increase the resources given by Nature to man is a task at once too noble and too useful not to induce the sympathy and earnest assistance of people in all parts of the world." Such is the aim of the Society. The last year has had good results. Foreign countries have all been made to give their quota towards increasing the material wealth of France and the knowledge of those interested in the Society. "China, hitherto so unknown, will soon have no secrets from us. A work on the ichthyology of the Celestial Land has given details as to the modes of pisciculture in that country." The financial position of the Society is satisfactory, the balance-sheet for 1872 showing receipts 54,944 fr. (2,200*l*.), and expenditure 45,704 fr. (1,828*l*.).

SOCIETIES AND ACADEMIES

LONDON

Royal Society, May 15.—On a Periodicity of Rainfall in connection with the Sun-spot Periodicity, by C. Meldrum, Director of the Meteorological Observatory, Mauritius. Communicated by Sir Edward Sabine.

Assuming that there is a sun-spot periodicity, in the course of which the sun undergoes a variation with respect to heat, or some other form of energy, we should expect to find a corresponding variation in the state of our atmosphere.

With this idea, it was some time ago determined to discuss the cyclones that had occurred during the last twenty-five years in the Southern Indian Ocean, and it was found, what had been often surmised, that they were more frequent and more violent in the maxima than in the minima sun-spot years.

It is well known that the cyclones of the Indian Ocean are attended with much rain, which is not confined to the body of the storm, but extends over wide areas. Years remarkable for cyclones, therefore, should be also years remarkable for rain; but to test this inference, with regard to the Indian Ocean, we had no rainfall statistics, except eighteen years' observations at Mauritius; and these were in every respect favourable, the rainiest years having been those in which cyclones were most abundant. In the absence of other data, the Brisbane and Adelaide rainfalls were consulted, and it was found that, like Mauritius rainfall, they indicated a periodicity. It was then surmised that there might be a rainfall periodicity generally; and that, if such was the case, both it and the cyclone-periodicity were concomitant effects of one and the same cause. This supposition having been strengthened by the results of an examination of the rainfall of England, it was resolved to examine all the rainfall tables (containing one or more sun-spot periods) that could be obtained. By comparison of an extensive series of weather statistics kept at a large number of places all over the world, the decided conclusion is that, with scarcely an exception, all the years of maxima and minima rainfall are within a fraction of the corresponding maximum and minimum sun-spot year.

Chemical Society, June 19.—Dr. Odling, F.R.S., president, in the chair.—Nine communications were read, of which the following are the titles:—1. "Researches on the Action of the Copper Zinc Couple on Organic Bodies III. on Normal and iso-propyl iodide," by J. H. Gladstone, F.R.S., and A. Tribe, being a continuation, in the propyl series, of the author's previous researches. 2. "On the Influence of Pressure on Fermentation, Part 4. The influence of reduced atmospheric pressure on the alcoholic fermentation," by Horace T. Brown, in which he finds that, under diminished pressure, the progress of the alcoholic fermentation is retarded in a remarkable way. 3. "On Cymene from different Sources, optically considered," by J. H. Gladstone, F.R.S. 4. "Note on the Action of Bromine on Alizarine," by W. H. Perkin, F.R.S. This reaction gives rise to *Bromalizarine*, an orange-coloured crystalline substance, possessing feebler dyeing properties than pure alizarine, the colouring principle of madder. 5. "On some Oxidation and Decomposition Products of Morphine Derivatives," by G. L. Mayer and C. R. A. Wright, D. Sc. 6. "On the Decomposition of Tricalcic Phosphate by Water," by R. Warrington. 7. "Communications from the Laboratory of the London Institution, No. XII.": "On the Nature and on some Derivatives of Coal-tar Cresol," by Dr. H. E. Armstrong and C. L. Field,

8. "On a new Tellurium Mineral, with Notes on a Systematic Mineralogical Nomenclature," by J. B. Hannay. 9. "Note on the Relation among the atomic Weights," by J. A. R. Newlands. The president, in adjourning the meeting until after the recess, congratulated the members on the number and importance of the papers that had been read during the session.

Zoological Society, June 17.—The Viscount Walden, F.R.S., president, in the chair.—Mr. Sclater laid before the meeting the first sheets of a catalogue of the birds of the Neotropical Region, prepared by himself and Mr. Osbert Salvin, and shortly to be published under the title "Nomenclator Avium Neotropicalium." The number of species included in it, as known to the authors, was 3,565.—Mr. Sclater exhibited and made remarks on a collection of birds recently made in New Guinea by Signor D'Albertis. The most remarkable of them was a new Paradise bird belonging to the Epimachine Section, but peculiar for its long incurved bill, which was proposed to be called *Drepanephorus albertisi*, after its discoverer.—Mr. J. W. Clark exhibited the skull of a Seal from the Northern Pacific, which appeared to be *Halicyon richardsi*, of Gray, and explained his reasons for regarding it as indistinguishable from *Phoca vitulina* of the North Atlantic.—A communication was read from Lord Walsingham, giving particulars as to the distribution of the different species of Deer and other Ruminants of Oregon and Northern California.—Dr. A. Leith Adams read a memoir on the osteology of the Maltese Fossil Elephants, in which was given the description of a large collection of remains discovered by him in Malta in the years 1860–1866. Dr. Adams referred these remains to two distinct species—a larger *Elephas mnaidriensis*, and a smaller—the *E. melitensis* of Falconer, and assigned *E. falconeri* of Busk to a smaller form of the latter species.—Mr. H. J. Elwes read a paper on the geographical distribution of Asiatic birds, in which he entered into the question of the best subdivision of the Indo-Malayan Region.—A communication was read from Mr. W. S. Atkinson, of Darjeeling, containing the description of a new genus and species of *Papilionidæ* from the South Eastern Himalayas, proposed to be called *Bhutanitis lidderdalii*.—Mr. R. B. Sharpe contributed the fourth of a series of papers on African birds. The present memoir dealt with the African Cuckoos, which were fully described and their geographical distribution pointed out.—Mr. R. B. Sharpe read a second communication, describing three new species of birds, proposed to be called *Macrodipteryx spekingi* from the Bay of Malimba, West Africa, *Chamætylas princei* from the Gold Coast, and *Baza erythrothorax* from Celebes.—Mr. Sclater read a paper on the Curassows, based mainly upon specimens now or lately living in the Society's Gardens, and gave details on their geographical distribution and on the variations of sex of the known species.—A communication was read from Mr. R. Swinhoe on Chinese Deer, with notices of two new species proposed to be called *Cervus kopschi* and *C. euopis*.—Mr. Sclater read a note on the genus *Ornithion* of Hautlaub, and the synonymy of the four known species.—Mr. A. H. Garrod read a memoir on certain muscles of the thigh of birds and their value in classification, founded principally upon the examination of a large number of specimens that had lived in the Society's collection. This meeting closes the Scientific Session 1872–73.

Anthropological Institute, June 17.—Prof. Busk, F.R.S., president, in the chair.—Mr. J. G. Waller exhibited a series of bronze implements discovered on the site of an ancient camp near Hythe, Kent; and Mr. J. E. Price exhibited pottery and bones of *Bos* found at New Southgate.—Lieut. C. S. Holland read a paper on "The Ainos." The following papers were also read:—Account of an interview with a tribe of Bushmans in South Africa, by G. W. Stow, F.G.S.—Specimens of native Australian languages, by A. Mackenzie.—A brief account of three microcephales, by Dr. John Shortt.—On a patoo-patoo from New Zealand, by Sir Duncan Gibb, Bart.—The healing art in the North of Scotland in the olden time, by Rev. Walter Gregor, M.A.—On a hypogeum at Valaquil, Isle of Uist, by A. Carmichael.—Heathen ceremonies still practised in Livonia, by the Baron de Bogouschefsky.—The westerly drifting of nomads from the 15th to the 19th century, Part XI.—The Bulgarians, by H. H. Howorth.

Entomological Society, June 2.—Sir Sidney S. Saunders, V.P., in the chair.—Mr. Müller exhibited a remarkable *Psyche* case, sent by Mr. Rothney from Calcutta. It was composed of thorns, all of equal length (about 1½ inches), arranged with the points all in one direction, so as effectually to guard the entrance against an enemy.—Sir Sidney Saunders exhibited a series of living Hymenopterous larvæ and pupæ in briar stems lately received from Albania. These stems having been split, showed the occupants in their natural cells. Specimens of the perfect insects reared from the larvæ were also exhibited.—Mr. Müller communicated some notes on the discovery by Dr. Joly, of Toulouse, of a nymph belonging to the genus *Oligoneuria*, the immature state of which had been hitherto quite unknown. Drawings of the upper and under sides of the nymph accompanied the notes.—Mr. Wollaston communicated a valuable paper "On the genera of the Cossonidæ." It comprised (1) a catalogue of the several groups, arranged systematically and tabulated; (2) full generic diagnoses, taken seriatim; (3) Observations (diagnostic and geographical) on each separate genus; (4) brief characters of 139 species not hitherto recorded; (5) a complete list of the particular members of the family (amounting in all to 253).—The Secretary read a letter he had received from Mr. Roland Trimen, of Cape Town, containing some remarks on the Rev. R. P. Murray's "Notes on Variations of Neuration observed in certain Papilionidæ," published in the Proceedings of the Society in November last, and referring certain cases of variation to reversion to ancestral characters, pointing to a remote community of origin between the Papilionidæ and the higher Heterocera.

BERLIN

Geographical Society, June 7.—Baron Richthofen, president, in the chair.—Dr. Neumayer spoke on methods of measuring the temperature of the water of the sea at great depth, and a new instrument for that purpose, invented by himself. The discovery of the fact that the bulb of an ordinary mercurial thermometer does not indicate correctly the temperature when subjected to the pressure of many atmospheres such as prevails at great depth, and that the errors of any single reading may react as much as 12 degrees of Fahrenheit, first led to the improved method of surrounding the bulb with a larger one filled with alcohol. The thermometrical errors, so far as they relate to the working of the instrument itself, are thereby nearly abolished. The difficulty, however, remains of ascertaining the point in the scale which the column of mercury reaches at any required depth of water. The various methods devised for overcoming it are chiefly directed towards the introduction of means for indicating the maximum and minimum points. No one of them fully answers this purpose. Any further improvement must therefore have for its object the reading of the thermometer while under water. A step in this direction was made by Mr. N. Siemens, but it was argued that the results arrived at by this method are not satisfactory, although it may eventually be improved. Dr. Neumayer's new principle is based upon the plan of devising a self-registering thermometer which may be lowered into the sea, and his first object was to find out a kind of light which should be able to do photographic work and yet not create errors by producing heat. The Geissler tubes answer these conditions, chiefly those filled with nitrogen, which emit a bright light and do not affect the temperature in any measurable degree. The new apparatus, which was exhibited and experimented with, consists of a large vessel of brass containing (1) two vertical thermometers, which perforate the bottom and protrude into an open compartment underneath, free to the access of water; (2) a galvanic battery, with two Geissler tubes inserted, running in front of, and close to, the thermometers; (3) two rolls of Talbot paper standing upright and immediately back of the thermometers, and revolving by means of a clockwork. As soon as the batteries are closed and the clockwork wound up, the luminous columns of the nitrogen cause the picture of the column of mercury to be reproduced on the photographic paper behind, together with all the lines marking the partition of the scale. The vessel is shut hermetically and lowered into the sea to any required depth. When raised again, the record of the temperature which the surrounding water had at any minute, and therefore at the particular depth to which the apparatus was then lowered, is read distinctly on the paper. An additional improvement was made by attaching on the top of the instrument a compass-card turning freely around its axis, and on the outside of the vessel a sort of wing, which will be directed by the current when the ship is in a slight motion By an ingenious contrivance the deviation of the direction of the wing from the north and south line of the card is indicated by the same photographic means. It is believed that the direction of the current at various depths will thus be determined.—Mr. Siemens

proposed to use chased copper in the place of brass in constructing the vessel, on account of its offering greater resistance to pressure, and believed to have already found satisfactory means for improving the instrument invented by himself and his brother.—Dr. Marthe gave an account of Khiwa based on the study of Russian literature on the subject, winding up with the suggestion, that the withdrawing of a large body of the water from the Amu for the irrigation of the oasis, deprived the lake Aral of so large a supply, that to this circumstance might be due the diminution its surface has suffered, and the fact of its present isolation. The water which before took its way through lake Aral to the Caspian, now evaporates from the rice-fields of Khiwa.

Geological Society, June 4.—Dr. J. Ewald in the chair.—Baron Richthofen drew attention to the activity recently displayed, according to newspaper reports, by several volcanoes of Japan, some of which have not been active for a long time, and gave an account of the distribution of volcanoes in Japan. The west and east portion of the aggregate body of the Japanese islands (leaving out of consideration the small inland passages), is in every way the direct continuation of the mountain system which occupies the south-eastern portion of China, the axial chain of which extends from the frontier of Annam to the island of Chusan, in the direction of W. 30° S.; E. 30° N. It is accompanied on either side by a number of parallel chains. The prolongation of the main portion of this group of linear chains passes through the island of Kiushiu to the great bend of Japan; and in that entire region of country, the structure of the hills, the rocks of which they are made up (chiefly Silurian and Devonian strata accompanied by granite), and the lines of strike are the same which were observed in south-eastern China. This first system is intersected, at either end, by another which runs SS.W., NN.E. On the west, it commences in Kiushiu, and extends southward in the direction of the Liu-Kiu islands, while on the east it constitutes the northern branch of the main island, and, with a slight deviation in its course, continues through the islands of Yesso and Saghalin. A third system, which does not properly belong to Japan, is indicated by the S.W. and N.E. line of the Kuril islands. The first system, where it occupies the breadth of the country for itself alone, is as free from volcanoes or any accumulation of volcanic rocks as it is in south-eastern China. The second is accompanied by volcanoes. But the greatest accumulation of volcanic rocks, as well as of extinct volcanoes, is found in the places of interference, or those regions where the lines of the two systems cross each other; and besides, in that region where the third system branches off from the second. To the same three regions of interference those volcanoes are confined which have been active in historical times. Some details were then given regarding the structure of Kiushiu. This island, although having its longer axis directed from north to south, is intersected, as it were, by several solid bars made up of very ancient rocks, and following the strike of W. 30° S., E. 30° N. They form high mountain barriers, the most central of which (south of the provinces of Higo and Bungo) rises to over 7,000 feet, and is extremely wild and rugged. Among the details regarding the volcanoes of Satsuma, particular attention was drawn to the fact that the various families of volcanic rocks have arrived there at the surface in exactly the same order of succession as is the case in Hungary, Mexico, the Great Basin, and many other volcanic regions, namely, 1st, Propylite, or trachytic greenstone; 2nd, Andesite; 3rd, Trachyte and Rhyolite; and 4th, the basaltic rocks. There is the greatest accumulation of mountain masses in Japan, one of the several chains rising to upwards of 11,000 feet in its summits. Among them are situated several gigantic volcanoes, such as Fusi-yama, the highest of all, Yatsunga-Jake, a series of elevated cones with extinct craters, and several others partly active and partly extinct. Those of the third group were not visited by Richthofen.—Prof. E. Weiss exhibited some curious octahedral crystals of Hausmannite, remarkable on account of certain re-entering angles and the striated aspect of the faces, and proved that the lines which caused this appearance were due to a kind of twin formation not hitherto observed.

PARIS

Academy of Sciences, June 23.—M. de Quatrefages, president, in the chair.—The following papers were read:—Second note on guano, by M. Chevreul.—New researches on the silent electric discharge, by MM. P. and A. Thenard.—Researches on chlorine and its compounds, by M. Berthelot. The author dealt with the compounds of chlorine with water and the protosalts.—A new series of observations on the solar protuberances; new remarks on the relations between protuberances and spots, by Father Secchi. The Rev. Father presented his observations for the last quarter, and then, in his letter, criticised Respighi's late remarks on the absence of the chromosphere over spots, which he maintains is not the case. He then gave an account of some experiments on sodium vapour, which, however, contained nothing new, and then proceeded to state that the line D_3 appears to him to coincide with one of the components of the D group which appears when the sun is near the horizon. He has also found a bright iron line between b_2 and b_3, and having examined the spectrum of iron with a battery of 50 cells, has seen 480 lines, but could not find 1474 Kirchhoff; he hopes to repeat this experiment, and if the results are same, he considers that the absence of Fe from the corona will be proved. With magnesium in the lamp, he finds the same nebulosity as is exhibited by the sodium lines, but it is accompanied by a banded spectrum of MgO; he thinks that if the nebulosity is also due to the oxide, that the occurrence of oxidation in the sun will be proved.—On the influence of atmospheric refraction as it affects the time of contact in a transit of Venus, by M. E. Dubois.—On the coloration and greening of *Neottia Nidus-avis*, by M. E. Prillieux.—On semi-diurnal barometric variations, by M. Broun.—On hot-air warming apparatus, by M. Ducrot.—A letter was received from M. de Lesseps praying the Academy to include his name among those of the candidates for the vacant seat of Académicien libre, vacant by M. de Verneuil's death.—On the constitution of the sun and the theory of the spots, by M. E. Vicaire.—On the production of methylic alcohol by the distillation of calcic formate, by MM. C. Friedel and R. D. Silva. The authors believe that formic aldehyde is first formed by the reaction $(CHO_2)_2Ca = CO_2Ca$? + H_2O + CH_2O, and that the aldehyde is converted into alcohol by the action of nascent hydrogen.—On terebene, by M. J. Ribau.—On the production of the rotatory power in the neutral derivatives of mannite, by M. G. Bouchardat.—An answer to a late note, by M. du Moncel, on the resistance maxima of induction coils, by M. Raynaud.

DIARY

FRIDAY, July 4.

Geologists' Association, at 8.
Archæological Institute, at 4.

THE ENDOWMENT OF RESEARCH

II.

IN a recent number attention was drawn to the public importance of original research in the Sciences, and it was insisted that certain funds which lie ready to the hand should be devoted towards the maintenance of those who undertake the national duty of extending the bounds of scientific knowledge.

In this article it is proposed to strengthen those positions by a reference to the already published evidence of the Royal Commission at present inquiring into "Scientific Instruction and the Advancement of Science." The object of the labours of the Commission is twofold, but concerning the former part nothing need now be said, except that regulated activity in independent investigation is the main condition upon which depends successful teaching alike in the individual professor, and the scientific schools of the nation.

The Commission was especially directed to ascertain how far the endowments of the Universities and Colleges might be directed to aid the needs of Science. On this point much valuable evidence was given by several distinguished members of our two wealthy Universities, and there was a general agreement of opinion that so far as Instruction and Examination are concerned, the Universities are showing a praiseworthy disposition to encourage their scientific students. On the other hand, it was universally admitted that the Oxford Science-school, despite the excellent teaching of its professors, is not progressing so well as might be expected, and that the University is lamentably deficient in that part of its functions which is concerned with the promotion of knowledge for its own sake.

Among the Oxford witnesses Sir B. Brodie, who was at the time that he gave his evidence Waynflete Professor of Chemistry, is conspicuous as well for the precision with which he pointed out the causes of the present defects, as for the definiteness of the scheme by which he proposed to remedy them. According to him, "Universities are Institutions of which the object is, in the first place, to promote scientific education and to diffuse scientific knowledge, and in the second place to preserve and to extend scientific knowledge." He was of opinion that "the latter of these duties is at present not sufficiently kept in view, whereas in old days the case had been different." His suggestions were that "the University should establish, on a larger scale than now, museums and scientific collections, for the present ones are organised too much with a purely educational object; and secondly (a point to which he attached by far the most importance), that the means of existence and of scientific study should be provided for certain professors or individuals, by whatever name they may be called, whose chief function should be scientific investigation and the representation and advancement of their various special Sciences."

He further went on to suggest that "these professors should be, to a great extent, separate from the ordinary teaching staff of the University, professors of the Science itself, rather than professors of the teaching of the Science:" that "in their lectures they should give to the public what they have attained for themselves, and have under them a limited number of pupils as assistants in their own original researches." The case of Liebig at Giessen will naturally suggest itself to our readers as an apt illustration of the particular mode of advancing Science here advocated; and from the evidence of Sir W. Thompson before the Commission it may be learnt that both at Glasgow and at Owens College a somewhat similar plan is being energetically carried out.

Sir B. Brodie, however, would appear with characteristic zeal to go even one step beyond this, for he instances as "a capital example of such a foundation as he would desire the Radcliffe Observatory at Oxford, where the observer gives no lectures at all, is not even attached to the University, but solely put there to do astronomical work. The Board of Curators, themselves not necessarily members of the University, having large funds at their disposal, give to the observer whatever he wants, whilst he on his part, as the sole evidence of his industry, makes an annual report on the condition of the observatory and the work done, and publishes certain tables." Here we also think that we have found, so far as the theory of the institution goes, an admirable model of the manner in which the cultivation of Science for its own sake may be endowed with great advantage to the country and without any manifest risk of sinecurism. In the language of the Dean of Christ Church, "we should very much like to see eminent men residing at Oxford only partially employed in teaching, but employing a great part of their time in scientific research."

With reference to the endowment of research here advocated it is necessary that a warning should be explicitly given against dangers which threaten from two different sides. On the one hand it is most important, in England more than in other countries, that the simple pursuit of Science as knowledge should not be confounded with the practical application of scientific truth to the numberless arts of modern civilisation. Applied Science is a profession which promises to become of a highly remunerative character. The analyst, the engineer, and the electrician may require pecuniary help and regulation from the Central Government for their technical schools, but they emphatically do not require to be themselves supported by national endowments. On the other hand, the ordinary scientific teacher at the universities, where not the poor but the rich as a rule are taught, should not in our opinion be regarded *quâ* teacher as the proper recipient of the funds of an endowment. It may very well be that while education in Science is struggling towards recognition, the teachers may claim some sort of aid to put them on a level with those branches of instruction which have the advantage of ancient prestige; it may also be thought advantageous that certain teachers should receive endowments, not for the tuition they give, but for the investigations they are carrying on independently of their other work; yet it must be granted that either of these cases is of an exceptional character.

On all hands are to be seen the disastrous consequences of endowing teaching proper, and of compelling original research to take its chance at the hands of the

amateur. It must happen that the professor (so called) will be constrained to give up the whole of his time to the duty which is most expected of him, and that original research will suffer both in quantity and in quality. The most general principles of political economy are sufficient to show that in a wealthy and moderately enlightened country the remuneration of teaching had better be regulated by the equitable standard which impartial competition will not fail to establish. It is for those subjects which, though of essential importance to the welfare of the country, are in themselves naturally unremunerative, that the old endowments for the promotion of education and knowledge, whatever may have been the particular means by which these ends were originally to be attained, are now required. Among these subjects disinterested application to pure Science is manifestly the chief.

In a subsequent article we propose to show that the funds of the Colleges cannot be more consistently applied than to this purpose, and that the progressive well-being of the Universities mainly depends upon the degree to which they are concerned in the advancement of knowledge. C.

THOME'S LEHRBUCH DER ZOOLOGIE

Lehrbuch der Zoologie. Von Dr. Otto Wilhelm Thómé; Pp. 416. (Brunswick: 1872.)

IF Germans wonder, not without reason, who buy our manuals of microscopic mounting, Englishmen may equally wonder for whom such books as Dr. Thomé's are written. We have technical treatises on special branches of zoology, and we have popular natural history books, but a manual like this would find a poor sale in England. It is a school manual, and its existence is explained by the introduction of zoology to some extent into the curriculum of the German gymnasia and much more into that of the Realschule, which more or less correspond to the "modern side" of our public schools, or may be described as answering in intention, though of course immeasurably superior in performance, to English "commercial schools." Whether zoology ought to form a regular part of school work, even where room is made by giving up Greek altogether and Latin more or less, is an important question. As a part of *education* in the proper sense of the word, it is so inferior in exactness, in conciseness, in facility of demonstration, and convenience for observation and experiment to such rivals as botany, physics, and even chemistry, that its claims may practically be ignored. Moreover, looking at school work from another point of view, it is obvious that any scheme of utilitarian *instruction* which is good for much must include ignorance of the greater part of human knowledge, in order to provide for acquaintance with the rest; and the first addition to the indispensable elements of reading, writing, and arithmetic would probably be claimed for geography, political economy, or the rudiments of hygiene, as more useful branches of knowledge than zoology. A boy with a bent for natural history would gain far more good from reading the bits of zoology in such books as the "Voyage of the *Beagle*," the "Malay Archipelago," or "Kosmos," and by collecting bird's eggs or butterflies, than he would by painfully wading through the details of Dr. Thomé's closely printed pages. And when zoology is taken up as a serious study by older students, most teachers will agree that the best plan is for them to begin by a careful study of a particular branch of the subject, with the help of such a handbook as Flowers' "Osteology of the Mammalia."

Looking to the object of the book, the reader will find Dr. Thomé's work fairly done. The first hundred pages are devoted to a popular sketch of human anatomy and physiology, from which all notice of generation and development is excluded. Otherwise it is as complete as the space will allow. The remainder of the book describes the several classes of animals, beginning with Mammalia and following the arrangement into seven types—Vertebrata, Mollusca, Arthropoda, Vermes, Echinodermata, Cœlenterata and Protozoa—which is now generally accepted among German naturalists. A diagram of these types is given, which might serve for a genealogical tree; but no hint of this intention is given. The sub-division into classes and orders is not particularly good. Thus among Mammalia the Sirenia are confounded with the Cetacea, Ray's obsolete distribution into Ungulata and Unguiculata is preserved, and the orders Ruminantia and Pachydermata appear, as if nothing had been done to clear up the real affinities of these groups since Cuvier published the "Regne Animal." The classification of birds is not more unsatisfactory than that of other writers; and in the class of fishes Müller's orders are commendably followed. Tunicata and Bryozoa are of course excluded from Mollusca, and help to fill the lumber-room of Vermes. A very large share is, as usual, given to the account of insects, while marine zoology and the Protozoa receive comparatively little attention.

Three hundred and fifty-eight woodcuts make an important feature of the work. Most of these are good in themselves and well printed. Those illustrating human anatomy and histology are the best, and almost all borrowed from Henle. No indication of this or any other source is given, but it is easy to recognise that some of the figures have been taken from the admirable cuts in Bell's "British Reptiles," others from Forbes, Milne-Edwards, and other well-known works; while some of the Mammalia appear to have been drawn from children's toys. Fig. 350, of a sponge, is a curiously modified reproduction of the original drawing in Grant's "Outlines of Comparative Anatomy" (p. 312). Of the thirty-one figures of birds, twenty-seven represent European species, and of these all but four are copied from Yarrell's British Birds. One excellent addition to each figure is a note of the relation it bears to the actual size of the animal represented, or of the average length of the latter. There are not many figures of anatomical details, but almost all are good, some being taken from Gegenbaur's "Vergleichende Anatomie."

To compare Dr. Thome's book as a whole with serious scientific treatises even of the second class, like that of Claus, would be unfair: but even as a "cram-book" it is inferior to Nicholson's Zoology: and it gives far too little space to descriptions of the habits and character of well-known groups like mammals, birds, and insects, to be really popular. Such books as Knight's "Museum of Animated Nature" are much more interesting and quite as scientific. P. S.

VALENTIN'S QUALITATIVE ANALYSIS

A Course of Qualitative Chemical Analysis. By William George Valentin, F.C.S., Principal Demonstrator of Practical Chemistry in the Royal School of Mines and Science Training Schools, South Kensington. (London: J. and A. Churchill. 1873.)

IT is a good sign of the present activity of scientific study in this country that there should have already been a call for a second edition of a work which only appeared two years back, in the early part of 1871.

The author has, in the second edition, separated the second part of his orignal work, and this, treating entirely of qualitative analysis, forms the volume now before us. The elements which occur in the main as bases are divided into five groups, and the first portion of the book is devoted to a careful study of each element of each group beginning with group V., a method the advantages of which will be seen by a very short study. The first 103 pages are devoted to this matter, and the attention of the student is then devoted to the study of the reactions of the acids. No particular grouping is here attempted, the acids being simply taken under the head of the principal element of each, *e.g.* sulphuric acid is followed by sulphurous acid, and that by hyposulphurous and hydrosulphuric acids. We remark here, by the way, that the polythionic acids are dismissed with the notice that they must be reserved for a more extensive course of study. A few of the more common organic acids are then referred to, and the whole matter treated of is shown in the condensed form as tables. In these we notice no important alterations from those of the edition of 1871, and of them we can, after considerable experience, speak in the highest terms, students soon learning to use them with great accuracy and despatch.

Mr. Valentin has stated in his preface that he purposely omits considering the rarer elements in his tables. In this we cordially agree with him as regards the tables intended for students, but we cannot help wishing that Mr. Valentin had put in the appendix some analytical information with regard to these bodies in a tabular form; as we feel sure that his great experience in the analysis of every possible kind of body would have enabled him to give valuable information to many who are compelled occasionally to make diligent search for elements which are not always met with. Many old students of the College of Chemistry will recognise an old friend on pp. 50 and 51 in the alternative table for group IIIA., it being no other than the old table used there up to the time of the introduction of the newer methods given at the end of the book.

We notice with pleasure that the analytical tables are published in a separate form, printed on De La Rue's parchment paper; this is certainly very good news for chemical students who have to use them. Who does not know the gradual process of obliteration and destruction by acids and alkalies which gradually, but surely, rendered his most carefully prepared and written analytical tables useless. It would be a great boon to all compelled to use books in the laboratory, if some modification of this material could be used for binding them. In conclusion we can strongly recommend the book to anyone desiring either to get or to give a thorough grounding in analytical chemistry; and the only fault we can find with it is that rather too profuse use is made of symbolical formulæ, for they are scarcely required in a book on analytical subjects only, and the first volume gives quite a sufficient amount of information on their use and nature. We hope that Mr. Valentin will some day give us a quantitative analysis.

R. J. F.

OUR BOOK SHELF

Celestial Objects for Common Telescopes. By the Rev. T. W. Webb, M.A., F.R.A.S. Third edition, revised and enlarged. (London: Longmans, Green, and Co, 1873.)

POSSESSORS of what Mr. Webb calls "common telescopes," will be pleased to have another edition of this most useful adjunct to their instruments, with corrections and additions up to the present time. Now that silvered glass reflectors are so cheap, and apertures little below six inches not uncommon in the hands of amateur astronomers, the author's definition of a common telescope is probably too limited, but these limits are extended as we proceed with the book and find mention of objects barely visible with nine inches. The advice on the use of telescopes, and the mode of observation is sound and good, and too much stress cannot be laid on the necessity of a good solid stand; a good telescope will be absolutely useless with an unsteady mounting. The description of the various phenomena to be viewed in the members of the Solar system may lead possessors of small telescopes to expect too much, the separation of Saturn's rings, the markings on Jupiter's satellites, to wit, although mention is made of the apertures required to view the features mentioned; but this may also make the book useful for work with larger instruments. We must take objection to the great contrast of light and shade, as is often the case in other works, in the cuts of Venus and Jupiter's moons, the dark markings on Venus being infinitely too black, they in reality being only just visible, with first-rate instruments, to a practised astronomer. Drawings of this kind only represent position and shape, but it must be remembered that an amateur expects to see through the telescope exactly what he sees in a drawing. One-third of the book is taken up with a selection of double stars and nebula, as in the former editions, with measures of position and distance up to later dates. Altogether the book will be found most useful to every incipient astronomer, but perhaps there may be too strong a tendency to star-gazing induced by it, and we should have been more gratified to have seen directions to readers having telescopes of certain sizes how to make their observations of real use and not a mere pastime. For instance, double image micrometers can be used on less apertures than 6-in. without clockwork; and some instructions in the use of them, and in reducing their observations so as to show the motions of binaries, would be of great service in teaching amateurs to do useful work; a hint, also, on drawing the ever-changing belts of Jupiter, any extraordinary spots on the sun, the larger nebulæ, and last, not least, the star clusters. As soon as amateurs have seen the planets and a few double stars, they should begin to make themselves useful, otherwise they soon get tired of the mere star-gazing and the telescope becomes to them a thing of the past.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Dr. Sanderson's Experiments and Archebiosis

IN last week's NATURE Dr. Sanderson expresses some sur prise that I was gratified by the facts recorded in his previou.

letter. My reasons were these. Dr. Sanderson's experiments in the eight successive cases in which he employed the temperature of 100° C. for twenty minutes were entirely confirmatory of my own, and were, moreover, so conducted as to refute the objections which have been urged by Dr. Wm. Roberts and others.

As to the bearing of Dr. Sanderson's experiments with higher temperatures and more prolonged periods of exposure to heat upon the general question of the independent origin of living matter, I wholly dissent from his now expressed conclusions, for the following reasons:—

In the first place his fluids were not kept sufficiently long before they were submitted to microscopical examination. Dr. Sanderson is quite mistaken in supposing that in examining his liquids within 3–6 days after their preparation he was following my method—more especially in cases such as these where the fluids have been exposed to temperatures higher than usual, or to 100° C. for upwards of twenty minutes. Three to six weeks have often elapsed before I thought it judicious to open my flasks (*See* "Beginnings of Life," vol. i. p. 355, p. 441, and Append. C.). In opening all his flasks at the end of 3–6 days, Dr. Sanderson lost the opportunity of watching the changes which might have ensued later in many of his experimental fluids—and hence lost his right to draw any conclusions from these abortive trials.

Secondly these experiments are open to another objection. Dr. Sanderson concludes from them that exposure to a temperature of 101° C. almost always arrests the tendency to fermentation in his experimental fluids. This conclusion I believe to be erroneous, because in the former series of experiments which I performed in his presence, and of which he recorded the results in your pages (NATURE, vol. vii. p. 180), fermentation occurred in the majority of cases in fluids which I have very good reasons for believing to have been raised to a temperature of 103·33° C.* The method recently employed by Dr. Sanderson for superheating his flasks was needlessly complicated, and the exact temperature to which they had been exposed was known only by inference—never by direct thermometric observation.

Leaving now the discussion of the experimental facts I come to the examination of Dr. Sanderson's inferences, which seem still more open to objection.

Dr. Sanderson, in common with most others, had up to the date of his witnessing my experiments, admitted that Bacteria and their germs were killed in all fluids with which he had experimented at the temperature of 100° C. (see "Thirteenth Report of Medical Officer of Privy Council, 1871.") It was, indeed, this conviction which inspired himself, and many others, with a strong disbelief in the results which I obtained with previously boiled infusions.

What remains, then, for Dr. Sanderson to do, prior to drawing inferences such as he now expresses, is to ascertain, by direct examination, whether the temperature of 100° C. is or is not fatal to the life of Bacteria. It is upon this that the interpretation of my results can alone depend. I have already contributed my share to the inquiry by several long series of experiments, each of which has led me to the same conclusion, viz., that Bacteria and their germs, when in the moist state, are killed at a temperature of 60° C. (See "Beginnings of Life," vol. i. p. 325-333; "Proceedings of Royal Society," No. 143, 1873; and another paper about to appear in the next number of the "Proceedings.") It is for Dr. Sanderson, or any competent observers who are sufficiently interested, to examine my experiments and results on this part of the subject, or else to devise others for themselves having a similar bearing.

If I am right in believing that 60° C. is the thermal death-point o Bac eria in the moist state, the conclusion which must be drawn from the now admitted results occurring in fluids which have been heated to 100° C. suffice for my argument as to the reality of Archebiosis. The further investigation of the results of raising fluids to higher temperatures for protracted periods is of great interest, but does not at all affect the question of the reality of Archebiosis; and Dr. Sanderson's present experiments have, therefore, none of the significance in the argument which he strangely enough appears to claim for them.

Briefly, having admitted that Bacteria arise in fluids which have been submitted to a temperature of 100° C., it is for Dr. Sanderson to show that they are not killed in fluids at 60° C., as I maintain that they are, before he can attempt with any effect to draw inferences of his own, or to criticise those which I have drawn on the subject of the independent origin of living matter.

H. CHARLTON BASTIAN

University College, July 7

* Dr. Sanderson was not aware of this fact, and says he does not know any means by which the temperature of a fluid boiling briskly in a vessel from which the steam escapes only through a capillary orifice, could be accurately estimated. The method which I adopted some months ago seems to possess this merit. I had a small maximum thermometer made for the purpose, 2½ in. in length, and graduated from 95°–115° C. Having straightened the neck of one of my retorts (capable of holding about two fluid ounces), it was filled with some hay infusion and the thermometer was introduced in such a way that its bulb remained in the midst of the fluid, about three quarters of an inch away from the glass. The long neck of the retort having then been drawn out and broken off (so as to leave the usual capillary orifice) the fluid was boiled for five minutes before the vessel was sealed. The thermometer was found to stand at 103·33° C. The retorts employed in my previous experiments with Dr. Sanderson were of the same size, and their contained fluids were boiled under precisely similar conditions. If larger flasks, containing more fluid, were employed the temperature would doubtless rise to a still higher degree owiog to a corresponding increase in internal pressure.

Dr. Bastian's Experiments

REGARDING Dr. Bastian's letter in NATURE of June 26, I am happy to be able to make a note of an experiment which is of interest and importance. I sealed a tube on to a flask of about 100 cc. capacity at right angles to the neck, and drew out the end so as to form a capillary orifice. About 30 cc. of water were put into the flask, and a thermometer in an india-rubber cork was wired into the neck. On boiling the water the steam had not issued during more than half-a-minute, before the temperature was 102° C., and in less than ten minutes it had reached 118° C.; fearing the safety of the apparatus, I did not proceed further, nor indeed did I wish to do more. The joint experiments of Drs. Sanderson and Bastian, then newly published in your paper, led me to this. My view being that Pasteur's experiments on milk, mixed with carbonate of lime, and the liquid known as "Pasteur's solution" mixed with carbonate of lime, conclusively show that liquids which ordinarily develop *Bacteria*, will, if they remain neutral after boiling at 100° C. also develop these organisms: raise the temperature to 110° C. and the *Bacteria* no longer show themselves.

Thus believing, I concluded that the absence of *Bacteria* in some of Drs. Sanderson and Bastian's flasks in which were placed neutral or only slightly alkaline infusions, was probably due to the liquids being heated above 100° C., by boiling in vessels with capillary orifices. That my supposition was correct is more than likely; in fact experiments with infusions confirmed it. That an aqueous solution may so easily be raised to 118° C. is a point in chemical manipulation which will be turned to advantage in the laboratory.

King's College, June 30 WALTER NOEL HARTLEY

Temperature and Pressure

THE climate of the island of Jamaica is remarkably uniform, not only at the sea-level, but also at places having the same elevation, so that the connection between temperature and elevation, or barometrical pressure due to that elevation, is easily obtained; and since the surface of the island is broken up by innumerable radiating and intersecting mountain ranges, among or upon which the houses are scattered, this connection becomes one of the most important features in its meteorology; but what renders it especially interesting, however, is the fact that the rate of the decrease of temperature in ascending the hills in this tropical climate is equal to the average rate of decrease found by balloon ascents made in England, as far as the irregularities of the results obtained from those ascents will allow us to judge.

In order to show that this is the case, let t_0 be the temperature at any place where the pressure is p_0, the temperature being expressed in degrees of Fahrenheit's scale, and the pressure in inches of mercury at 32°; let t and p be the corresponding quantities at any other place above the former; then if λ be constant and equal to 3°·23, the equation

$$t_0 - t = \lambda(p_0 - p)$$

will represent the connection between temperature and pressure; or in words, for every inch the barometer may fall, the thermometer will fall 3°·23.

If we take mean annual values, at Kingston $t_0 = 78°\cdot8$, $p_0 = 29\cdot97$in.; and at Newcastle, the garrison of the white troops, $t = 67°\cdot0$, $p = 26\cdot31$in.; so that $\lambda\,(p_0 - p) = 11°\cdot8$, which is exactly equal to the observed difference of temperature.

Again at Craigton, the residence of his Excellency the

Governor, which is between the two former places with respect to both position and elevation, $t = 70^\circ \cdot 5$, $p = 27 \cdot 41$ in., from observations kindly made for me by Captain Lanyon, A.D.C.; so that the calculated difference of temperature between Kingston and Craigton is $8^\circ \cdot 3$, the observed difference; and the calculated difference between Craigton and Newcastle is $3^\circ \cdot 55$, which is only $0^\circ \cdot 05$ too large. And since the equation has been found to hold good under different circumstances at lower elevation, we may suppose that it is strictly true for Jamaica.

With regard to balloon ascents, I have before me two tables, one compiled by Sir John Herschel, and the other by Prof. Loomis, from more recent observations, and these are brought into the same form in the following table in order to compare them; the first column contains the fall of the barometer in inches, the second contains the corresponding fall of temperature from Herschel's Meteorology, the third from Loomis's Meteorology, and the fourth contains the mean of the numbers in the second and third, which we shall consider to be the average results obtained from balloon ascents.

1	2	3	4	5	6
$p_0 - p$	H	L	$t_0 - t$	Calc.	Diff.
In.	°	°	°	°	°
2	3·0	10·1	6·6	6·3	+ 0·3
4	6·8	17·3	12·1	12·6	− 0·5
6	11·3	23·2	17·3	18·9	− 1·6
8	16·9	29·0	23·0	25·2	− 2·2
10	23·6	34·7	29·2	31·5	− 2·3
12	31·4	40·5	36·0	37·8	− 1·8
14	40·8	46·3	43·6	44·1	− 0·5
16	51·8	51·7	51·8	50·4	+ 1·4
18	63·7	56·1	59·9	56·7	+ 3·2

Now if we take $t_0 - t = \quad (p_0 - p)$, we shall get nine equations of condition for finding λ; the most probable value of this quantity is $3^\circ \cdot 15$, which hardly differs from the value found in Jamaica. Again, if we calculate $t_0 - t$ and employ this value of λ, we get the fifth column, and it will be noticed that the differences in the last column between the observed and calculated quantities are very small when we consider the great differences between the second and third column.

Therefore the equation $t_0 - t = \lambda\,(p_0 - p)$ holds good for about two-thirds of the whole atmosphere, and if it holds good for the remaining third, by putting $p = 0$, we shall obtain the difference between the temperatures at the lowest and highest strata of the atmosphere; this difference is about 94°, so when the temperature at the surface of the earth is 50°, the temperature at the superior limit of the atmosphere must be −44°.

Since the temperature falls $3^\circ \cdot 15$ for every inch the barometer may fall, or for every 945 ft. we may ascend (when that temperature is about 50° and the elevation low), the temperature in England will fall 1° for every 300 ft.; this has been always acknowledged, and we now see that it is a consequence of the more general law which connects temperature and pressure throughout the atmosphere.

Now though we may suppose that λ has this value for all insular climates, yet it cannot have the same value for continental climates, on account of the higher temperature of the land; but still there is every reason for supposing that, at any given instant of time, λ is constant for all points in the same vertical line; and when it has been determined from the observed temperatures and pressures at any two points in that vertical, our equation becomes especially adapted for the barometrical measurement of the distance between them.

It only remains for me to say that I have already used the equation when making a series of observations among the hills in the north of England, and always found it true when the weather was settled, and sufficient time and care taken in obtaining the mean temperatures of the different strata of air.

Jamaica MAXWELL HALL

Larvæ of Membracis serving as Milk-cattle to a Brazilian Species of Honey-bees

THE connection between the ants and the Aphides has long since been generally known; in the proper season we always find ants very busy on those trees and plants on which the Aphides abound, and if we examine more closely we discover that their object in thus attending upon them is to obtain the saccharine fluid which they secrete from two setiform tubes placed one on each side just above the end of the abdomen, and which may well be denominated their milk (Kirby and Spence, "Introduction to Entomology," 7th edition, p. 335). It has also long been observed and described, that not only do the Aphides yield this repast to the ants, but also the Cocci, and that in the tropical regions of India and Brazil, where no Aphides occur, the ants milk the larvæ of several species of Cercopis and Membracis (Kirby and Spence, p. 336; Westwood, "Modern Classification of Insects," II. p. 434). Recently Prof. F. Delpino, of Vallombrosa, near Florence, observed the same connection

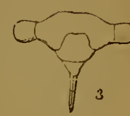

Fig. 1.—Lateral view of larva. Fig. 3.—Front view of head of imago.

between *Formica pubescens* and *Tettigometra virescens* ("Bolletino Entomologico," anno IV. Settembre 1872). But, as far as I know, it has never been observed hitherto that honey-bees also nourish themselves by the secretion of certain hemipterous insects. Hence the following observation, made some months ago by my brother, Fritz Müller (Itajahy, Prov. St. Catherina, Brazil) may be worth publishing.

Among the great number of species of Melipona and Trigona which, in the tropical and subtropical regions of America, as is known, occupy the place of our hive-bee, there is one small species of Trigona which has only once been found by my brother on flowers (of *Sicyos angulata*), and which seems to nourish itself in a very strange manner. He once found a multitude of them spread over the body, already strongly putrifying, of a large toad; the interior of the large open mouth of the toad was filled with these bees, probably sucking the putrid juice of the dead body. On another occasion he saw a great

FIG. 2.—Lateral view of imago.

number of the same species of bees in the putrifying intestines of a hen. Repeatedly he saw them sucking the juice flowing out of trees.

In consequence of other observations this same species of Trigona is supposed by my brother to suck the secretion of the larvæ of a certain hemipterous insect belonging to the genus Membracis, or to a closely allied one. As I do not precisely know the name of this supposed milk-cow, I here give the illustration of its larvæ and imago, drawn from specimens sent me by my brother.

He found the pedunculi of the flowers of *Cassia multijuga* pretty frequently occupied by societies of larvæ of this species closely crowded together. Amongst these larvæ there was present a great number of the above-mentioned Trigona, marching all the day long amongst and upon them. When taken between the fingers, the larvæ of Membracis immediately emitted a little drop of a limpid fluid from the upward bent tip of their abdomen—probably a sweet fluid, for the sucking of which the larvæ are visited by the Trigona.

Unfortunately the specimens of this Trigona, enclosed in a letter sent me by brother, arrived here quite broken, so as not

to be determinable; but in a future number of this journal I hope to be able accurately to name both the supposed milker and the supposed milk-cow.

Lippstadt HERMANN MÜLLER

Free-Standing Dolmens

MR. LUKIS, in a paper recently read before the Society of Antiquaries, nominally "On certain Erroneous Views respecting the Construction of French Chambered Barrows," but really a method of criticising severely Mr. Fergusson's work on the "Rude Stone Monuments," states that it is an "*error*" to suppose that the Dolmens of that country were ever free-standing; in other words, he lays down the "rule," "there were no free-standing dolmens in France." The announcement that, with regard to monuments of whose fashioners we know absolutely nothing, a universal negative of this kind can be safely laid down as a law, would be startling, did it not come from one who is backed by such extensive inductive evidence as is Mr. Lukis. His "rule" was "established by the extreme rarity of the instances." This being the case, he calls those "in error" who would, from these instances, form a small class, or species of dolmen. As, in an essay on the Cornish sepulchral monuments, which you recently most kindly reviewed at length, I am committed to this latter view—one, by the way, which I had struck out for myself before the appearance of the "Rude Stone Monuments,"—will you kindly permit me to call your attention to one structure which I have ventured to place, and shall still venture to place, in the discarded class? I do so as a protest against the dictum of Mr. Lukis being extended to our British examples, before a careful scrutiny has been made of *every* monument of the kind from one corner of our islands to the other. On this single instance, such as it is, it must be clearly understood that I build no theory; it will be for others to judge whether it does not afford some evidence of the difference in construction and use of the dolmen or table-stone proper, and the kist-vaen cromlech; one thing only I will add, that, limited as my experience is to the monuments of Britain, I shall not be exposed to the temptation of explaining away any observed fact in order to reconcile a doubtful comparison. Without feeling that I am guilty of "dabbling in archæology," or of setting forth "any dogmatic expositions of hypotheses" (!!), or of "establishing my proposition from second-hand information," or in short of being the victim of any very "erroneous view" (all which faults Mr. Lukis finds in those who differ from him), I consider that the following facts justify my statement that the monument I am about to describe always was, as it is now, a free-standing dolmen.

At Lanyon, in the parish of Madron, Cornwall, stands a tripod dolmen, or cromlech, consisting of three slim pillars of unhewn granite supporting on their summits a horizontal stone over 40 ft. in circumference and averaging 20 in. thick. In 1815 it fell; but previous to its fall a man on horseback could sit upright underneath the cap-stone. In 1824 it was again set up; but two drawings had been made of it in its pristine condition, one by Canon Rogers in 1797, and the other by no less accurate a draughtsman, half a century before, namely, by my ancestor, Dr. Borlase. Both these drawings agree in representing the extreme slimness of the pillars; their distance apart; and the great height of the monument; features which render it not unlike a gigantic three-legged milking stool. Then, as now, there was no mound about it, as there is in the case of each and all of the kist-vaen cromlechs. It stood on a low bank of earth, and the area had been often disturbed by treasure seekers. No houses are near it which could have received the stones of a denuded mound. Added to this, it is difficult to see how a kist-vaen, or *septum* of any kind, could have been formed beneath the cap-stone. Had a wall of *small* stones been built up from pillar to pillar the weight of the superincumbent mound must have forced them inwards, a catastrophe which the "dolmen-builders" were always most careful to avoid. Secondly, had *large* stones placed on edge formed the walls of the kist, how is it they are *all* removed, while every other cromlech in the district retains them? But, laying aside this evidence, my strongest proof is yet to come. The interment in this instance was *not in the kist at all*. A grave had received the body six feet under the natural surface of the surrounding soil, and within the area described by the structure. This being the case, of what use could an enclosed kist have been; or why should the cenotaph be covered in at all? Add to this again, that on the southern side of the structure, and so near it that a mound over the monument must inevitably have covered it up, stands a little circular ring cairn of the ordinary type, in the centre of which I found the remains of an inner ring, which, though now rifled, had doubtless contained an interment. Must I then explain away in deference to superior experience or received opinion each and all of the above facts, in order to reconcile this monument with those which seem to be totally different structures, viz., the kist-vaens?* Should I not by so doing be sacrificing a fact to an hypothesis, and is not that hypothesis of such a nature that even a single instance well established must shake it to its foundation? Should I not incur a charge of erroneousness equal to, if not greater, than that which Mr. Lukis brings to bear on all who differ from him?

No one can wish more than I do to see errors expunged, and the truth in these matters arrived at; but I must confess that I cannot see how this will be brought about by confronting one hypothesis with another equally dogmatic, and more universally inclusive. WILLIAM C. BORLASE

Castle Horneck, near Penzance

Fertilisation of the Pansy

I AM glad to be able to confirm, to some extent, from observation, Mr. Bennett's theory of the fertilisation of the Pansy, given in NATURE, vol. viii. p. 49. I watched a considerable number of specimens of *Viola tricolor* on a grassy hill-top where the smaller insects were very numerous and busy, and twice saw them entered by a minute fly. In the first case the insect was dusty with pollen when it arrived. It settled on the lower petal and walked up one of the black lines to the gap in the ring of anthers, through which it entered with some difficulty—leaving some of the foreign pollen on the stigma as it passed. When it came out it had still more pollen on it than when it went in, and again in passing the stigma it left some on it. It paused a moment on the lower petal to clean itself, and left a little ball of pollen on the hairs on one side of the stigma. In the second case, the insect alighted first on one of the upper unmasked petals, turned round and round as though seeking the guiding lines, and flew off to the lower petal, where, without hesitation, it followed the guiding lines as the other had done. After it had passed the stigma there was no pollen visible on its surface; but after it had come out, almost the whole of the lower half was covered. In each case the passage through the ring of anthers seemed rather a struggle. There were many bees about, but I did not see any of them visit the Violæ, although they were almost the only flower near. A. T. MYERS

Penrith, June 30

European Weeds and Insects in America

A CANADIAN friend writes to me:—"I have heard or seen it mentioned as a fact that European weeds and insects introduced into America flourish for a while, but after fifty or sixty years gradually disappear: for instance, that the Hessian fly (so called from having been brought over by the Hessian troops in their hay in the war of independence) has died out or ceased to give trouble, though at one time it totally destroyed the wheat crops of New England. I do not know how far the facts have been tested, or how far they are owing to improved agriculture."

This statement, if true, is obviously of great importance. Can any of your correspondents confirm or disprove it?

JOSEPH JOHN MURPHY

Old Forge, Dunmurry, July 4

CHLOROPHYLL COLOURING-MATTERS †

IT would be impossible for me not to look upon the appearance of such a work as the one recently published by Dr. Gregor Kraus with much satisfaction, since the chief object of the author is to call the attention of his countrymen to the value of the spectrum-microscope in studying the colouring-matters of plants. He commences with a description of the instrument, and says that, though originally designed for the examination of microscopical objects, it is not only as useful as any

* The only other tripod dolmen in Cornwall, viz., that at Caerwynen, is also a free standing one (within the memory of man, at least), whereas the *kist-vaens* are *one and all* partially covered by their envelope.

† "On the Chlorophyll Colouring-Matters." ("Zur Kenntniss der Chlorophyllfarbstoffe und ihrer Verwandten"). By Dr. Gregor Kraus. (Stuttgart, 1872.)

larger spectroscope for the study of the absorption of solutions, but indeed in many cases preferable. He describes two different kinds of eye-piece, viz., a simple form made by Merz, and the far more complete Sorby-Browning, with the method of measurement proposed by Mr. Browning, and expresses his regret that the value of such instruments has been almost altogether overlooked by German botanists. In treating on the application of the apparatus, the author very justly points out the great advantage of having a bright illumination, without too much dispersion, and the importance of being able to examine the spectrum of a leaf or any other object in its natural state, in order to ascertain whether the colouring matters dissolved out from a plant by any solvent do really occur in it, or are products of decomposition. I would also myself add that in some cases the difference between the spectrum of a substance in a free state and when dissolved is so considerable that care must be taken not to conclude that there has been actual decomposition, until the character of the spectrum of the solid substance, in a free state, has been ascertained; and even when the spectra are very nearly the same, the position of the absorption-bands may differ sufficiently to make it possible to determine whether a colouring-matter naturally exists in a free state or dissolved in water, or in an oil, according as it is or is not soluble in water. The fact of being thus dissolved or not is in some cases, probably, a question of considerable physiological importance, since the existence of solid particles along with, or even actually surrounded by, a liquid capable of dissolving them, points to a very different origin and relation to structure to those of a substance merely dissolved in the juices of a plant or an animal. The solution of such a colouring-matter is sometimes one of the first changes that occur in decomposition, as if set free from minute cells.

Having explained the general methods employed, and given a list of the chief publications connected with the subject, the author proceeds to the consideration of various colouring-matters found in plants. If I had written this review immediately after the work was published, I should have expressed my agreement with the greater part of the author's conclusions; for they are those to which a most careful experimenter would be led by employing the methods generally known at that time; but during the last year I have devoted myself exclusively to this particular subject and have been led to employ almost entirely new methods of investigation, and the result is that I must now point out a number of particulars in which I think the author's conclusions are not altogether correct. These new methods consist chiefly in the more or less perfect separation of the different substances by means of bisulphide of carbon, alcohol, and water, used in varying proportions, and in a somewhat peculiar manner; in the employment of what I have named *photo-chemical analysis*, or the use of light as a reagent, so as to destroy some constituents, and leave others, which perhaps could not be separated by chemical methods; and in studying and comparing together all classes of plants, especially the lower cryptogamia, when growing in various conditions; and not only in examining them qualitatively but also in determining the relative amount of the different colouring-matters by a method of comparative quantitative analysis. I will not now enter into detail, but refer to a paper recently communicated to the Royal Society, on comparative vegetable chromatology, in which I have given a complete general description of the methods I have used, of the facts I have observed, and of the conclusions drawn from them, which have a very direct bearing on some of the most important questions in biology, and enable us to examine them from a new point of view.

One great value of the author's work consists in its giving a very complete account of the researches of previous investigators, which I have myself found extremely useful; since so much that has been written is difficult of access. At the same time, since the methods employed were often altogether unsuitable, and most of the experiments are now known to have been made with mixtures, many of the results are of very little more than historical interest. The work also contains three excellent lithographed plates of the spectra of the various colouring-matters in a natural or altered condition. The whole subject is treated in an admirable manner, and I trust that no one will think that I wish in any way to detract from the author's merit in taking this opportunity to illustrate the application of the methods which I think should be employed in such researches.

The coloured solutions obtained from leaves are very complicated mixtures. It is not at all unusual for them to contain as many as ten different coloured substances. The progress of our knowledge has to a great extent depended upon the application of improved methods, which have made it possible to distinguish the various constituents of these mixtures. The author has himself pointed this out, and shown that what was at one time called chlorophyll, and looked upon as a single substance, consists of a mixture of a bluer-green substance with a yellow substance. This kind of analysis had however previously been considerably extended. In a very short paper,* containing no description of the methods of experiment, or of the separate colouring-matters, Stokes said that his researches had led him to conclude that the chlorophyll of land plants is a mixture of four substances, two green and two yellow, and in my late paper I have shown that by the newer and improved methods it is easy to prove that there are not only these two green substances, one a blue-green and the other a yellow-green, having perfectly distinct and characteristic properties, though confounded together by nearly all other experimenters, but also four or even five perfectly distinct yellow substances. These various colouring-matters I have named *blue chlorophyll*, *yellow chlorophyll*, *orange xanthophyll*, *xanthophyll*, *yellow xanthophyll*, *orange lichnoxanthine*, and *lichnoxanthine*. They are all insoluble in water, and soluble in bisulphide of carbon, and besides one or two products of decomposition, they must all have been present in what has sometimes been called chlorophyll, and looked upon as a single compound. Now, almost the only points in which I feel compelled to differ from the author are those cases in which the new methods of examination prove that what he regarded as a single colouring matter is in reality a mixture of two or even more, which can be separated, and do occur separately in particular plants. Thus, for example, in Plate II. Fig. 1, he gives a drawing of the spectrum of the blue-green colouring matter of *Deutzia scabra*, showing six absorption-bands. Now, I feel persuaded that this colouring-matter must have been a mixture of three different substances, viz. my blue chlorophyll, my yellow chlorophyll, and the product of the action of acids on blue chlorophyll. The bands numbered 1, 2, 3, and 6 are mainly due to blue chlorophyll. Part of No. 1 and No. 5 are due to yellow chlorophyll, and the band No. 4 clearly indicates the presence of a small quantity of the product of the action of acids on blue chlorophyll. This is almost always present when the preparation is made in the manner adopted by the author, but by neutralising the acid of the juice by carbonate of ammonia, or still better by employing a plant that has an almost perfectly neutral juice, chlorophyll may be obtained which gives a spectrum almost absolutely free from any such band.

In the spectrum shown by Plate III. Fig. 1 of the blue-green colouring-matter of an *Oscillatoria*, the bands of yellow chlorophyll are absent, for it does not exist in such *Algæ*, but the broad band shown at about 500 of the author's scale, not seen in the spectrum of the chlorophyll of *Deutzia*, must have been mainly due to orange xantho-

* Proceedings of the Royal Society, 1864, xiii. p. 144.

phyll, which occurs in considerable quantity in *Oscillatoriæ*, but is relatively almost absent in green leaves, and would not be separated by the method employed by the author in making the preparation. Comparatively pure blue chlorophyll, prepared from olive *Algæ* by the method described in my late paper, gives a spectrum free from absorption over the whole of the green and a considerable part of the adjoining blue. The close resemblance, and yet decided difference, between the spectra of the blue-green colouring matter obtained from the two above-named sources, did not escape the author's notice, but the methods employed were inadequate to prove that both contained the same principal blue-green substance, mixed in one case with one, and in the other case with another colouring matter. I may here say that the relative amount of blue and yellow chlorophyll differs very much in different classes of plants, and even in the same plant, when in different conditions, and the study of this variation leads to results of great interest in connection with vegetable physiology; since, amongst other things, it proves that leaves normally very yellow are quite unlike those that have turned yellow in autumn, but analogous to those which are abnormally yellow owing to absence of light, as though the deficiency of chlorophyll were in both cases due to weak constructive energy; and the comparative absence of yellow chlorophyll in such abnormally weak plants, belonging to the highest classes, causes their colouring to approximate much more closely to that of those of much lower organisation.

I must say that I object to the term chlorophyll being applied, as by the author, to a mixture of the various yellow substances belonging to the xanthophyll group, with one or both of the above-named green substances. The green colour of leaves is due to them, and they are both actually green, one a blue-green and the other a yellow-green, so that the terms blue chlorophyll and yellow chlorophyll appear to me very appropriate. It would be better and extremely convenient to adopt some such word as *endochrome*, to express any mixture of coloured substances contained in the cells of plants, which has no reference to any particular tint of colour.

The very materially different position of the chief absorption-band of chlorophyll when in the leaves of plants and when in solution has been noticed by the author, and likewise the difference in its position when the chlorophyll is dissolved in different liquids. He attributes this entirely to the difference in the density of the liquid, and concludes that in the leaves the chlorophyll may be combined with or dissolved in some dense substance. The difference in the position of the bands of chlorophyll is very small compared with the difference seen in the case of some other colouring-matters, and by carefully studying the question I have come to the conclusion that the position of the bands does not vary directly with the density of the solvent, or with any other general property, but is so independent that it is desirable to look upon it as a special property, and to call it the *absorption-band-raising* power. The extent to which the bands are raised varies much according to the substance; but, as an apparent rule, if the position is altered, they lie nearer to the blue end when the substance is dissolved than when in a free state. In accordance with this view of the subject, it appears as though in the living plants chlorophyll and various other colouring-matters exist in a free state, not combined with or dissolved in any wax, fat, or oil, with which, however, they often combine when the plant is boiled in water, and with which they are combined when a solution is evaporated to dryness, so that the spectrum of such a dried-up material may, and often does, differ most materially from that of the endochrome in the living plants. As an illustration of the opposite case, I may refer to the spectra of yellow flowers, which often show that the endochrome is combined with, or dissolved in, a fat or oil. When not thus combined, the spectra are so different that the colouring-matter might be, and sometimes has been, looked upon as distinct, before the true cause of the difference was known. The microscope alone could not decide this question, since visible granules might not be the free colouring-matter, and, on the contrary, it might be free, and the particles too small to be separately visible.

H. C. SORBY

(*To be continued.*)

RECENT RESEARCHES ON THE PHYSIOLOGICAL ACTION OF LIGHT

THE arrangements by which the mind is brought into relation with the outer world are—(1) a terminal organ, such as the retina, or the intricate structures of the internal ear, or the touch corpuscles of Wagner, for the reception of impressions from without; (2) a nerve, endowed with a special sensibility peculiar to the sense for the conveyance of influences from the terminal organ to the brain; and (3) a sensorium or brain in which, on receiving these influences, changes occur which give rise to the phenomena of consciousness.

Nerves act, therefore, as conductors from the terminal organs to the brain. These terminal organs are specially fitted for the reception of specific stimuli, such as the vibrations of the ether, which, when received by the retina, induce a change which is transmitted to the brain, and gives rise to the sensation of light, or the condensations and rarefactions of the air which cause sound. But though specially fitted for these stimuli, the terminal organs may be affected in other ways. For example, mechanical pressure on the retina produces a sensation of light, and many diseases affecting the auditory apparatus by compression, cause agonising sensations of sound. The nerves in connection with the sense organs are termed nerves of special sense, because they are supposed only to convey influences which are derived from the special terminal organs with which they are connected. These nerves are, however, themselves not affected only by the special stimulus which affects their respective terminal organ. As is well known, the optic nerve is not affected by light—a fact easily demonstrated by Marriot's experiment showing that the retina at the entrance of the optic nerve is insensible to light.

The nature of the specific change produced on the terminal organs by the action of external stimuli has not hitherto been experimentally examined. Let us take the case of the eye. Numerous hypotheses have been advanced. The action of light on the retina has been conjectured to be a mere communication of vibrations, an intermittent motion of portions of the optic nerve, an electrical effect, a heating effect, or a photographic effect like that produced by light on a sensitive surface, but up to this time there has been no experimental evidence in support of either of these views.

The result of investigations made by Mr. Dewar and Dr. McKendrick, of Edinburgh, communicated to the Royal Society of Edinburgh, has been to show that the specific effect of light on the retina and optic nerve is a change in the electro-motive force of these organs. They have been able to demonstrate this by the following arrangements:—The eye of a frog rapidly killed by pithing is dissected out of the orbit, so as to leave the sclerotic entirely free from muscle, and a portion of optic nerve intact. This preparation is placed on the cushions of the well-known arrangement of Du Bois-Raymond for collecting electric currents from animal structures, consisting of two zinc troughs, carefully amalgamated on the inner surface, and containing pads of Swedish filter-paper moistened with a solution of pure neutral sulphate of zinc. To protect the eye from the irritating action of the sulphate of zinc, thin films of sculptors' clay, mixed with a weak solution of chloride of

sodium, each worked out to a point, are placed on the pads of filter paper. From each of the troughs a wire passes to a key so as to enable the experimenter to stop the current at pleasure, and from thence the current passes to the galvanometer. They then lay the eye on a glass support between the cushions, and carefully adjust the clay-points so that the one touches the cornea and the other the transverse section of the optic nerve, or the one may touch the surface of the nerve and the other its transverse section. On opening the key, a deflection of the galvanometer needle is at once obtained to the extent of about 600° of the galvanometer scale, placed at a distance from the mirror of the galvanometer of about 26 inches. This deflection is a measure of the natural electro-motive force of the eye. The troughs are now covered over with an apparatus consisting of a double shell made of glass, and containing between the walls one inch of water so as to absorb all heat rays, and lastly a wooden box is placed over the whole, having a draw-shutter so as to enable the experimenter to admit light at pleasure. A gas flame is placed before the shutter. The arrangement is now complete. After observing that the deflection indicating the electro-motive force in the dark is constant, the shutter is now withdrawn so as to admit light. At that instant, that is, on the impact of light, a change is perceived in the electro-motive force. There is at first an increase, then a diminution, and on the removal of light there is another increase of the electro-motive force. Occasionally, in consequence of the dying of the nerve, there is only a slight increase, then a diminution, but the rise on the removal of light is always constant. The amount of change in the electro-motive force by the action of light is about 3 per cent. of the total. There has been no difficulty in demonstrating the effect in the eyes of the following animals, after removal from the body: *Reptiles*, Snake; *Amphibia*, Frog, Toad, Newt; *Fishes*, Gold Fish, Stickleback, Rockling; *Crustacea*, Crab, Swimming Crab, Spider Crab, Lobster, Hermit Crab. The greatest effect was observed in the case of the lobster, in the eye of which Messrs. Dewar and McKendrick found a modification in the electro-motive force by the action of light to the extent of about ten per cent. With the eyes of birds and mammals they had great difficulty. It is well known that in these animals the great source of nervous power is an abundant supply of healthy blood. Without this, nervous action is soon arrested. This law, of course, holds good for the retina and optic nerve. When, therefore, they removed the eye-ball with nerve attached, from the orbit of a cat or rabbit recently killed, and placed it in connection with the clay points, they found a large deflection which quickly diminished, but all sensitiveness to light disappeared within one or two minutes after the eye had been removed from the animal. This fact of itself shows that what has been observed is a change depending on the vital sensibility of the parts. It was therefore necessary to perform the experiment on the living animal under chloroform. By so fixing the head that it could not move, and by removing the outer wall of the orbit so as to permit the clay points to be applied to the cornea and nerve, the same results have been obtained in the case of the cat, rabbit, pigeon, and owl.

Without going into minute detail, which the space allowed for this short article will not admit of, the results of this inquiry have been as follows:—

1. That the specific effect of light on the eye is to change the electro-motive force of the retina and optic nerve.

2. That this last applies to both the simple and to the compound eye.

3. That the change is not at all proportional to the amount of light in lights of different intensities, but to the logarithm of the quotient, thus agreeing with the psycho-physical law of Fechner.

4. That those rays, such as the yellow, which appear to our consciousness to be the most luminous, affect the electro-motive force most, and that those, such as the violet, which are least luminous, affect it least.

5. That this change is essentially dependent on the retina, because if this structure is removed, while the other structure of the eye lives, though there is still an electro-motive force, there is no sensitiveness to light.

6. That this change may be followed into the optic lobes.

7. That the so-called psycho-physical law of Fechner does not depend on consciousness or perception in the brain, but is really dependent on the anatomical structure and physiological properties of the terminal organ itself, inasmuch as the same results as to the effect of light are obtained by the action of the retina and nerve without the presence of brain.

The method of investigation pursued by Messrs. McKendrick and Dewar is applicable to the other senses, and opens up a new field of physiological research. The specific action of sound, of the contact of substances with the terminal organs of taste, and of smell, may all be examined in the same manner; and we are in hopes of soon seeing results from such investigations.

ON THE FERTILISATION OF FLOWERS BY INSECTS AND ON THE RECIPROCAL ADAPTATIONS OF BOTH

II.

In what manner the hive- and humble-bees obtain the honey of the flowers

IN the last number the use the bee makes of its complex sucking machinery, when emptying the deepest honey-tubes or spurs accessible to it, was stated in detail; we have now to show the different movements and positions the separate parts of the mouth undergo, when the bee is obtaining honey less deeply placed, or when it is about to collect the pollen of flowers, or when it folds together the whole sucking apparatus into the cavity of the head in order to employ its jaws or to rest.

(2) In order to obtain the honey out of tubes or spurs of less depth the bee need not turn the cardines forward; these remain at rest in their backward position, the tongue remains consequently embraced by the maxillæ and labial palpi, and only the base of the tongue is alternately protruded and withdrawn, by which motion the terminal whorls of hairs are alternately immersed into the honey and withdrawn into the sucking-pipe.

(3) While the bee, in order to suck honey, flies from flower to flower, it carries its sucking apparatus stretched forward so as to be able to put it directly into the opening of the honey-tube, but its tongue is perfectly enclosed between the labial palpi and the maxillæ; the delicate whorls of hairs are protected by that from any injury they might receive, when introduced into the flowers, and the terminal joints of the labial palpi are not prevented from serving as feelers. Consequently during the flying from flower to flower the base of the tongue is folded into the extremity of the tubular mentum, the cardines are turned backwards, whilst the lora can be directed downwards (Fig. 4), forwards (Fig. 2) or backwards, in proportion as the bee is about to obtain the honey from shorter or longer tubes.

(4) The parts of the mouth must be held in the very same position when the bee wishes to pierce tender cellular textures by means of the tips of its maxillæ. It executes this sort of process, sometimes in order to obtain the fluids of juicy flowers which do not secrete nectar, as for instance *Hyacinthus orientalis*, *Orchis mascula*, *morio* and *latifolia*, sometimes in order to break open honey-tubes which are too deep to be emptied by the bee in the

regular way. Thus, for instance, *Bombus terrestris*, having of all our humble-bees the shortest tongue, forcibly opens the honey-tubes of *Aquilegia*, *Trifolium pratense*, *Pedicularis sylvatica*, and many other flowers; sometimes by piercing the corolla by the tips of its maxillæ, sometimes by biting through the corolla by means of its jaws, and then steals the honey by guiding its proboscis into the honey-tube through the self-made opening.

(5) When collecting the pollen of flowers the hive- and humble-bees moisten, as is well known, the pollen with honey before stripping it off with the brushes of their feet from the anthers and amassing it on the outside of the posterior tibiæ. During this process the maxillæ and the labium are commonly bent beneath the breast, as in

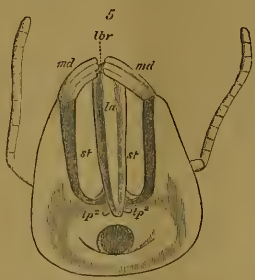

Fig. 5.—The sucking apparatus of a humble-bee (*Bombus hortorum*, L. ♀) placed in the hollow underside of the head, seen from beneath (7 : 1).

inaction, almost as shown in Figs. 5 and 6, the jaws are opened, the labrum is raised, the opening of the mouth is brought near the pollen to be collected, and a drop of honey is spit out upon this pollen; often also the bee before moistening the pollen with honey frees it while still enclosed in the anthers by chewing the anthers with its jaws.

In quite a different manner I saw the hive-bee proceed when collecting the loose, dry pollen of *Plantago lanceolata*, so easily shaken out. By vehement movements of its wings the bee maintains itself, steadily humming, at the same place in the air, close before the anthers, the pollen which it is about to collect; in this position it has its sucking-apparatus stretched forward, but the tongue quite enclosed between the laminæ and labial palpi, and spits out of the sucking-pipe formed by these parts a drop of honey upon the anthers. Then it grasps very hastily, with the brushes of its anterior legs, amongst

Fig. 6.—Lateral view of the same head.

the anthers, and strips off the moistened pollen from them, while the dry pollen of the neighbouring anthers also shaken out, is disseminated, forming a little cloud of dust. Consequently, also in this case the bee carries the base of its tongue folded into the mentum, and the cardines turned backward, precisely in the same manner as when flying from flower to flower, or when piercing honey-tubes by the tips of the laminæ.

Plantago lanceolata and other plants with equally loose, dry pollen, scattered by the wind, are honeyless; on the other hand the pollen of all honey-flowers is collected by the hive- and humble-bees when holding their sucking organs retracted, whilst the honey of these flowers is obtained by their sucking-organs stretched forward; hence it follows that hive-bees, humble-bees, and all the bees which are in the habit of moistening the pollen before collecting it, can never suck honey and collect pollen at the same time, but are obliged to perform alternately these two actions after having commenced with sucking honey, of which they are in need for moistening the pollen to be collected, whereas all the bees which collect the pollen without moistening it, as, for instance, the Andrena, Osmia, and Megachile, are often observed sucking honey and collecting pollen at the same time.

(6) When the bee is about to employ its jaws, or when it wishes to rest, it rests the whole sucking apparatus in the hollow in the under-side of the head, by

Fig. 7.—Two whorls of scales of the terminal portion of the tongue of a blue Brazilian Euglossa (or Chrysantheda); the scales of each whorl alternating with those of the following one (80 : 1).

effecting all the four foldings above described, and bends beneath the breast those parts which do not find any room in this excavation, viz., the tongue, and the labial palpi and laminæ enclosing it, as shown in Figs. 5 and 6.

Everyone who has observed in nature the activity of the hive- and humble-bees will be surprised by the ease with which the numerous movements just described are effected by them. Nevertheless, when sucking honey out of tubes or spurs, they experience a sensible loss of time by so repeatedly protruding and retracting the tongue. This loss of time seems to be avoided by a very singular contrivance lately discovered in some Brazilian bees by my brother, Fritz Müller. In these bees all the rings of the terminal portion of the tongue, from the tip to the sheath, formed by the labial palpi and laminæ, are provided, as shown in Fig. 7, with whorls of narrow-stalked, broad scales instead of hairs, and these scales, lying closely upon one another, form together a tube around the prominent

Fig. 8.—Gradations between hairs and scales.

portion of the tongue which probably enables the bee to suck the honey out of the longest flower-tubes accessible to it without needing to retract the tongue.

The first scale-bearing rings within the sheath of the tongue, offering numerous gradations by which hairs and scales graduate into each other, as shown in Fig. 8, indicate precisely the degrees of variability by which natural selection arrived at the broad narrow-stalked scales clothing the prominent portion of the tongue.

Hermann Müller

ON THE ORIGIN AND METAMORPHOSES OF INSECTS*

VIII.

FOR the next descending stage we must, I think, look among the Infusoria, through some such genus as Chætonotus or Ichthydium. Other forms of the Rotatoria, such for instance as Rattulus, and still more the very remarkable form discovered last year by Mr. Hudson,† and described under the name of *Pedalion mira*,

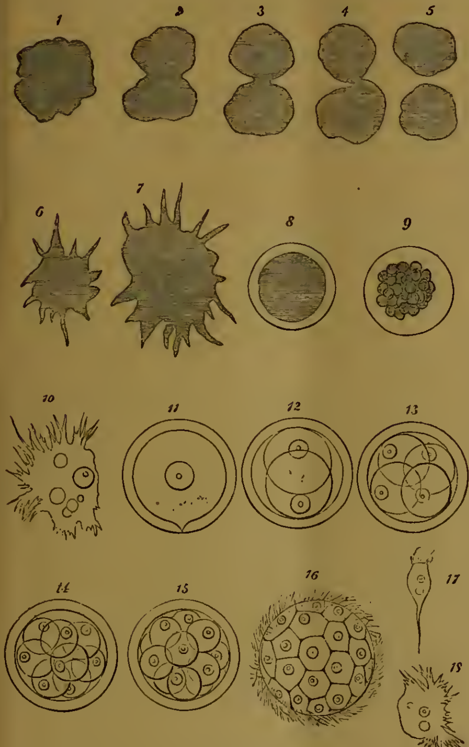

PLATE 5.

Plate 5.—Figs. 1—5, Protamœba. 6—9, Protamyxa Aurautiaca. Haeckel Beit. zur Monog. der Moneren, Pl. 1. 10—18, Magosphœra planula Haeckel lc., P.l. 5.

seem to lead to the Crustacea through the Nauplius form. Dr. Cobbold tells me that he regards the Gordii as the lowest of the Scolecida; Mr. E. Ray Lankester considers some of the Turbellaria, such genera for instance as Mesostomum, Vortex, &c., to be the lowest of existing worms; that is to say, if we exclude the parasitic groups. Haeckel ‡ also regards the Turbellaria as forming the nearest approach to the Infusoria. The true worms seem, however, to constitute a separate branch of the animal kingdom.

We may take the genus Prorhynchus,§ for instance, as an illustration of such a low type (Fig. 59), which consists of a hollow cylindrical body $1\frac{1}{2}$ to 2″′ long, containing a straight simple tube, the digestive organ.

But however simple such creatures as these may be, there are others which are far less complex, far less differentiated; which therefore on Mr. Darwin's principles may be considered still more closely to represent the primæval ancestor from which these more highly developed types have been derived, and which, in spite of their great antiquity, in spite of, or perhaps in consequence of their simplicity, still maintain themselves almost unaltered.

Thus the form which Haeckel has described * under the name of *Protamœba primitiva*, Pl. 5, Fig. 1—5, consists of an entirely homogeneous and structureless substance, which continually alters its form; putting out, and drawing in again, more or less elongated processes, and creeping about like a true Amœba, from which, however, Protamœba differs in the absence of a nucleus. It seems impossible to imagine anything simpler; indeed, as described, it appears to be an illustration of properties without structure. It takes into itself any suitable particle with which it comes in contact, absorbs that which is nutritious, and rejects the rest. From time to time a constriction appears at the centre (Pl. 5, Fig. 2), the form approximates more and more to that of an hour-glass (Pl. 5, Fig. 3), and at length the two halves separate, and each commences an independent existence (Pl. 5, Fig. 5).

In the true Amœbas, on the contrary, we find a differentiation between the exterior and the interior: the body being more or less distinctly divisible into an outer layer and an inner parenchym. In the Amœbas, as in Protamœba, multiplication takes place by self-division, and nothing corresponding to sexual reproduction has yet been discovered.

Somewhat more advanced, but yet of great simplicity, is the *Protomyxa aurantiaca*, discovered by Haeckel † on dead shells of Spirula, where it appears as a minute orange speck, which shows well against the clear white of the Spirula. Examined with a microscope the speck is seen to be a spherical mass of orange-coloured, homogeneous, albuminous, matter, surrounded by a delicate, structureless, membrane (Pl. 5, Fig. 8). It is obvious from this description that these bodies closely resemble eggs, for which indeed Haeckel at first mistook them. Gradually however the yellow sphere broke itself up into smaller spherules (Pl. 5, Fig. 9), after which the containing membrane burst, and the separate spherules, losing their globular form, crept out as small Amœbæ (Pl. 5, Fig. 6), or amœboid bodies. These little bodies moved about, assimilated the minute particles of organic matter, with which they came in contact, and gradually increased in size (Pl. 5, Fig. 7) with more or less rapidity according to the amount of nourishment they were able to obtain. They threw out arms in various directions, and if divided each section maintained its individual existence. After a while their movements ceased, they contracted into a ball, and again secreted round themselves a clear structureless envelope.

This completes their life-history as observed by Haeckel, who found it easy to retain them in his glasses in perfect health, and who watched them closely. It also coincides very closely with that of the Gregarinæ, another group of singularly egg-like organisms.

As another illustration I may take the *Magosphæra planula*, discovered by Haeckel on the coast of Norway.

In one stage of its existence (Pl. 5, Fig. 10) it is a minute mass of gelatinous matter, which continually alters its form, moves about, feeds, and in fact behaves altogether like the Amœba just described. It does not however remain always in this condition. After a while it contracts into a spherical form (Pl 5, Fig. 11). and secretes round itself a structureless envelope, which, with the nucleus, gives it a very close resemblance to a minute egg.

* Continued from p. 167.

* Monographie der Moneren, p. 43.
† Monographie der Moneren, p. 10.

Gradually the nucleus divides itself, and the protoplasm also separates into two spherules (Pl. 5, Fig. 12); these two subdivide into four (Pl. 5, Fig. 13), and so on (Pl. 5, Fig. 14), until at length thirty-two are present, compressed into a more or less polygonal form (Pl. 5, Fig. 15). Here this process ends. The separate spherules now begin to lose their smooth outline, to throw out processes, and to show amœboid movements like those of the creatures just described. The processes or pseudopods grow gradually longer, thinner, and more pointed. Their movements become more active, until at length they take the form of ciliæ. The spherical Magosphœra, the upper surface of which has thus become covered with ciliæ, now begins to rotate within the cyst or envelope, which at length gives way and sets free the contained sphere, which then swims about freely in the water (Pl. 5, Fig. 16), thus closely resembling Synura, or one of the Volvocineæ. After swimming about in this condition for a certain time the sphere breaks up into the separate cells of which it is composed (Pl. 5, Fig. 17). As long as the individual cells had remained together they had undergone no changes of form, but they now show considerable contractility, and gradually alter their form, until they become undistinguishable from true Amœbæ (Pl. 5, Fig. 18). Finally, according to Haeckel, these amœboid bodies, after living for a certain time in this condition, return to a state of rest, again contract into a spherical form, and secrete round themselves a structureless envelope.

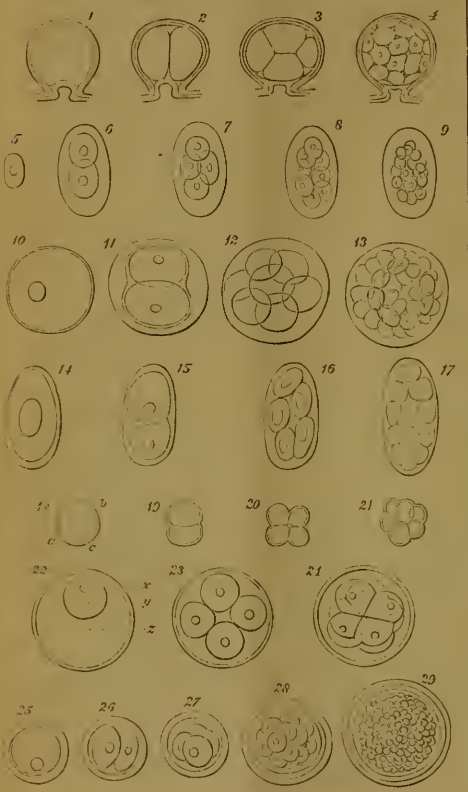

PLATE 6.

Plate 6.—Figs. 1—4, Yolk-segmentation in Laomedea; 5—9, in Filaria; 10—13, in Echinus; 14—17, in Lacinularia; 18—21, in Purpura; 22—24, Amphioxus; 25—29, Vertebrata.

It may be said, and said truly, that the difference between such beings as these and the Campodea, or Tardigrade, is immense. But if it be considered incredible that even during the long lapse of geological time such great changes should have taken place as are implied in the belief that there is any genetic connection between insects and these lower groups, let us consider what happens under our eyes in the development of each one of these little creatures, in the proverbially short space of their individual life.

I will take for instance the first stages, and for the sake of brevity only the first stages, of the life history of a Tardigrade.* As shown in Fig. 60, the egg is at first a round body, with a clear central cell—the germinal vesicle; it increases in size, and after a while the yolk and the germinal vesicle divide into two (Fig. 61), then again into four (Fig. 62), and so on, just as we have seen to be the case in Magosphœra. From the minute cells (Fig. 63) arising through this process of yolk-segmentation, the body of the Tardigrade is then built up.

It is true that among the Insecta generally, normal yolk-segmentation does not occur, though the first stages of development in Platygaster, as figured by Ganin (ante Figs.), closely resemble those of the Tardigrada.

Though I will not now attempt to point out the full bearing of these facts on the study of embryology generally, yet I cannot resist calling attention to the similarity of the development of Magosphœra with the first stages of development of other animals, because it appears to me to possess a significance, the importance of which it would be difficult to over-estimate.

Among the Zoophytes Prof. Allman thus describes † the process in Laomedea, as representing the Hydroids (Pl. 6, Fig. 1, represents the young egg):—"The first step observable in the segmentation-process is the cleavage of the yolk into two segments (Pl. 6, Fig. 2), immediately followed by the cleavage of these into other two, so that the vitellus is now composed of four cleavage spheres (Pl. 6, Fig. 3)." These spheres again divide (Pl. 6, Fig. 4) and subdivide, thus at length forming minute cells, of which, as in the previous cases, the body of the embryo is built up.

In Pl. 6, Figs. 5—9 represent the corresponding stages in the development of a small parasitic worm—the *Filaria mustelarum*—as given by Van Beneden.‡ The first process is that within the egg, which represents, so to say, the encysted condition of Magosphœra, ; the yolk divides itself inte two balls (Pl. 6, Fig. 6), then into four (Pl. 6, Fig. 7), eight, and so on, the cells thus constituted finally forming the young worm. I have myself observed the same stages in the eggs of the very remarkable and abnormal *Sphærularia bombi*.§

Among the Echinoderms M. Derbès thus describes the first stages (Pl. 6, Figs. 10—13) in the development of the egg of an Echinus (*Echinus esculentus*):—"Le jaune, commence à se segmenter, d'abord en deux, puis en quatre et ainsi de suite, chacune des nouvelles cellules se partageant à son tour en deux."|| Sars has observed the same thing in the starfish.¶

* See, for instance, Kauffmann, Uber die Entwickelung und systematische stellung der Tardigraden. Zeits. f. Wiss. Zool. 1851, p. 220.

§ Natural History Review, 1861, p. 44.

|| Derbès, Ann. des Sci. Nat. 1847, p. 90.

¶ Fauna Littoralis Norvegiæ, pl. viii.

In the Rotatoria, as shown by Huxley in Lacinularia,* and by Williamson in Melicerta,† the yolk is at first a single globular mass, the first changes which take place in it being as follows :—"The central nucleus becomes drawn out and subdivides into two, this division being followed by a corresponding segmentation of the yolk. The same process is repeated again and again, until at length the entire yolk is converted into a mass of minute cells." Among the Crustacea the total segmentation of the yolk occcurs among the Copepoda, the Rhizocephala, and Cirripedia. Sars has described the same process in one of the nudibranchiate mollusca ‡ (Tritonia), Muller in Entochocha,§ Haeckel in Ascidia,‖ Lacaze Duthiers in Dentalium.¶ Figures 18 to 21, Pl. 6, are taken from Koren and Danielssen's ** memoir on the development of *Purpura lapillus.*

Figs. 22-24 show the same stages in a fish (Amphioxus) as given by Haeckel, and it is unnecessary to point out the great similarity.

Lastly, figures 25 to 29, Pl. 6, are given by Dr. Allen Thomson,†† as illustrating the first stages in the development of the vertebrata.

I might have given many other examples, but the above are probably sufficient, and show that the processes which constitute the life-history of the lowest organised beings, very closely resemble the first stages in the development of more advanced groups; that, as Allen Thomson has truly observed,‡‡ "the occurrence of segmentation and the regularity of its phenomena are so constant that we may regard it as one of the best established series of facts in organic nature."

It is true that yolk segmentation is not universal in the animal kingdom; that there are great groups in which the yolk does not divide in this manner,—perhaps owing to some difference in its relation to the germinal vesicle, or perhaps because it has become one of these suppressed stages in embryological development, many instances of which might be given, not only in zoology, but, as I may state on the authority of Dr. Hooker, in botany also. But however this may be, it is surely not uninteresting, nor without significance, to find that changes which constitute the life-history of the lowest creatures, form the initial stages even of the highest.

Returning to the immediate subject of this work, I have pointed out that many beetles and other insects are derived from larvæ closely resembling Campodea, that other insects come from larvæ more or less like Lindia, and it has been shown over and over again that in many circumstances the embryo of the more specialised forms resembles the full-grown representatives of lower types. I conclude, therefore, that the Insecta generally are descended from ancestors resembling the existing genus Campodea, and that these again have arisen from others belonging to a type represented more or less closely by the existing genus Lindia.

Of course it may be argued that these facts have not really the significance which they seem to me to possess. It may be said that when Divine power created insects, they were created with these remarkable developmental processes. By such arguments the conclusions of geologists were long disputed. When God made the rocks, it was tersely said, he made the fossils in them. No one, I suppose, would now be found to maintain such a theory, and I believe the time will come when it will be generally admitted that the structure of the egg, and its developmental changes, teach us as truly the course of organic development in ancient times, as the contents of rocks teach us the past history of the earth itself.

NOTES

SIR CHARLES WHEATSTONE has been elected a Foreign Associate of the French Academy of Sciences in place of the late Baron Liebig.

MR. COLE's retirement from public service is now completed, and the Treasury have awarded him the full pension usually granted to officers who have completed fifty years of public service. Although Mr. Cole quits the South Kensington Museum, he will continue to assist in promoting the diffusion of Science and Art applied to productive industry as the Acting Commissioner for the estate purchased out of the surplus funds of the Exhibition of 1851. This estate at present comprehends the Horticultural Gardens, the buildings of the Annual International Exhibitions, and the Royal Albert Hall. Measures are in progress for forthwith commencing the National Training School for Music. A meeting of those interested in the Testimonial which it is proposed to present to Mr. Cole, will be held in Willis's Rooms to morrow at 3 o'clock. Those who know best how much Mr. Cole has done for the encouragement and advance of Science, will, we are sure, be the most ready to take part in this well-deserved testimony to the value of his services to the public.

AFTER the alarming rumours that have recently found their way into the newspapers, it is a great relief to receive what appears to be really authentic news of the safety of Sir Samuel and Lady Baker. It appears, from the message received by the *Daily Telegraph*, that they arrived at Khartoum on the 29th of June. It is stated that the party had been as far south as a place called Mosindi, near the chief village of Kamrasi, the King of Unyoro, which would be in about 1°·45′ N. lat., and about 80 miles to the east of the shores of the Albert Nyanza. Here Sir Samuel is said to have been attacked by a chief named Kabriki, and, on his retreat, by a party of slave-hunters. He seems to have established another Egyptian station at a place called Fatiko, somewhere to the south of Gondokoro. The story about the Albert Nyanza and Lake Tanganyika being one, which forms part of the news published by the *Daily Telegraph*, is certainly very startling news, and must at present be received with great caution, though the *Telegraph* correspondent declares he received it direct from the lips of the Emancipator of Central Africa himself.

MR. AUBERON HERBERT'S Select Committee on the Wild Birds Protection Act has met three times, and examined a good many witnesses. It would not be fair to take the report, published in the *Field*, of what passed at those meetings as strictly correct, but if it be at all true, the doubt, before expressed in these pages (NATURE, May 1, 1873), as to any real good resulting from the inquiry, can hardly be otherwise than justified. The questions put by the chairman indicate, as far as we perceive, that he has a very hazy idea of the bearings of the whole subject, and no one of the other members appears to have sufficient knowledge of any part of it to follow home by cross-examination any of the evidence offered in reply. By many of the witnesses birds are regarded as divisible into two groups—the useful and the noxious—a simple classification which will be amusing to naturalists. Such witnesses also think that the destruction of the latter should be encouraged and the former protected—being quite innocent of the fact that no laws in the world will make most "useful" birds more numerous than they already are. It seems to us that the only way in which an inquiry of this kind could be satisfactorily conducted would be by a Royal Commission, in which the scientific element, so

unhappily lacking in a Parliamentary Committee, should be adequately represented. The birds which suffer a perfectly preventible persecution to such an extent that their extermination may shortly be expected, appear to be thought hardly worthy of the Committee's consideration, though it was to save them that the British Association's efforts were chiefly directed.

THE Highland and Agricultural Society of Scotland have taken a praiseworthy step in memorialising Government to do what is undoubtedly their duty to the country, appoint a Commission of competent scientific men to inquire into the causes of the ever-recurring potato-disease, a disease which is a national calamity. How far advanced is the American Government in matters concerning the national welfare is well shown by the memorialists, and even Portugal is far enough ahead of us to appoint a Government Commission to inquire into the vine-disease.

THE Executive Committee of the Fund for erecting a memorial to the late John Stuart Mill have resolved that a portion of the funds raised be devoted to erecting a bronze statue of Mr. Mill in some public situation in the City of Westminster, which he for a time represented in Parliament, the remainder to the foundation of Scholarships, open to the competition of candidates of both sexes, in Mental Science and Political Economy; subscribers to the fund being invited to say to which of these purposes they wish their subscriptions to be devoted.

THE Council of University College, London, has determined to throw open to women next session another of its ordinary classes, that of jurisprudence, conducted by Prof. Sheldon Amos.

WE are glad to see from a circular which has been sent us, and which we would recommend to the attention of all teachers, and to all interested in science-teaching in schools, that the Charterhouse School of Science has met with signal success during the past, its first, session. There is an excellent staff of scientific lecturers, which we are glad to see is to be increased, the training is thorough and practical, and a large and well-fitted chemical laboratory, besides other scientific apparatus, is to be added to the School. The School is in connection with the Science and Art Department, and we hope that during next session, which commences on September 20, the attendance will be as satisfactory as during the past. Attached to the circular is a form to be filled up by intending students, and accompanying it is a well-drawn up time-table. The fees are remarkably low.

AT a meeting of the Council of the Royal School of Mines, held on Saturday, July 5, the following gentlemen received the diploma of Associate of the Royal School of Mines:—Mining and metallurgical division—E. Jackson, J. A. Griffiths, C. Law. Mining division—A. G. Phillips. Metallurgical division—J. W. Westmorland, S. W. Davies, J. C. Jefferson, H. S. Bell. Geological division—G. Smith. The following Scholarships and Prizes were also awarded:—The two Royal Scholarships of 15*l.* each, for first year's students, to Mr. H. Carter and Mr. A. J. Meeze. To second year's students: H.R.H. the Duke of Cornwall's scholarship of 30*l.* for two years, to Mr. C. Lloyd Morgan, and the Royal Scholarship of 25*l.* to Mr. S. A. Hill. The Edward Forbes' medal and prize of books, for Natural History, to Mr. G. Smith. The De la Beche medal and prize of books, for mining, to Mr. Edgar Jackson. The Murchison medal and prize of books, for geology, to Mr. C. Lloyd Morgan.

SIGNOR AUGUSTO RIGHI, Demonstrator of Physics in the University of Bologna, has just published an elaborate memoir "On the Composition of Vibratory Motions" (*Tipi Gamberini e Parmeggiani, Bologna*). The memoir is of a high order, and is worthy the attention of all physicists specially interested in acoustics. The subject is mathematically treated, and is illustrated by twenty-one admirable plates.

MR. W. CARRUTHERS has just issued his official Report for 1872, of the Department of Botany in the British Museum. The additions to the Herbarium during the year are spoken of as large and important, rendering more and more pressing the necessity of increasing accommodation for the arranged Herbaria. The species included under several of the natural orders, both in the General and in the British Herbarium, have been entirely re-arranged during the year; and much use has been made of the Herbarium by botanists preparing monographs for a number of different publications. Numerous interesting additions have also been made to the Structural Series, both in the Fruit, the Fossil, and the General Collection.

WE have received "Lecture Extra, No. 8" of the *New York Tribune*, containing twelve lectures by Prof. Louis Agassiz, on various important subjects connected with animal life; besides a lecture on "Vestiges of Antiquity," by Dr. A. Le Plongeon, "The Art of Dyeing," by Prof. Chandler, a long article on the Fossil Man of Mentone, and a detailed account of Prof. Marsh's discoveries in the Rocky Mountains. All these lectures and articles are copiously illustrated and well printed, and the whole is a marvellous pennyworth. The *Tribune* deserves the greatest praise for the important part allotted to science in its programme.

IN the just published number of the *Journal of Anatomy and Physiology* there is a valuable paper by Prof. Rutherford, of King's College, on the cause of the retardation of the pulse which follows closure of the nostrils in the rabbit, in which he shows that this retardation is not the direct effect of reflex action, as previously supposed, but is due to the arrest of respiration which necessarily attends the blockage in the air-passage; for the retardation does not commence directly the nostrils are closed, but is delayed for about four seconds, and if the trachea is kept open it does not occur at all. Ammonia applied to the nose produces similar effect, because the animal ceases to breathe for a time, as it closes the nostrils in order to prevent the entrance of the irritating fumes. Prof. Rutherford finds that after the vagi have been divided, the arrest of respiration does not cause the pulse to become slower, which is in favour of the supposition that the retardation which normally occurs is produced by the action of the impure blood on the cardio-inhibitory centres in the medulla oblongata.

THE *Journal of Botany* records the death of two British botanists of reputation, Mr. James Ward, of Richmond, Yorkshire, one of the most active and experienced botanists of the North of England, and Mr. James Irvine, of Chelsea, who wrote a "London Flora" in 1838, and was one of the editors of the old *Phytologist*.

A FLORA of Cheshire is shortly to appear under the superintendence of the Hon. J. L. Warren.

WE have to record the following earthquakes this week:—THE Imperial Meteorological Observatory of Constantinople reports that on June 20 there were several smart shocks of earthquake at Bagdad at night, and again on the 21st at noon. A strong shock of earthquake was felt at Alpago, Italy on July 3. A volcanic eruption, accompanied by discharges of hot cinders, is stated to have commenced at Farra. The waters of the Lake Santa Croce, a few miles south-east of Belluno, were boiling. Three shocks of earthquake were felt at Buffalo, U.S., on the morning of July 6, causing the buildings and shipping to rock.

THE Synopsis of Laboratory Work in Practical Organic Chemistry at the Teachers' Training Class at South Kensington for July, contains seventy practical problems in chemistry, with directions for their solution.

A GREAT International Exhibition is to be held at Philadelphia in 1876.

IN the *Weekly Salt Lake Tribune* of June 7, a lecture is reported on the Sandwich Islands by Dr. Winslow, who resided there for several years. The light in which he represents the natives of Hawaii to regard the death of Captain Cook will be new to many of our readers. "The natives were astonished and distressed at their own barbarity, and they treated the remains of Cook as they did those of their highest chiefs and as if he had been a god. They dissected the big bones from his legs and arms, as a mark of the highest honour they could confer on their own beloved dead. They exposed the rest of his remains before their great idol in the temple, and sacrificed hogs and dogs to his memory and to appease the gods for his and their own sins. His entrails had been placed carefully in a calabash and left aside, in order for burning in some subsequent ceremony, when a boy (an intelligent old man of some 75 or 80 years in 1845, with whom the Doctor had conversed), supposing them to be the entrails of a hog, cut off a piece and roasted it on coals and ate it. When the officers of the ships, in their subsequent intercourse with the natives to recover the remains of Captain Cook, earned that nothing was left of them but the big bones, which were delivered up to them, they fancied his flesh had been devoured by the savages, and a howl went up from the British public and the Christian world that the newly-discovered Hawaiians were natives and cannibals. Such was not the case at first, and has never been the case. Their first experience with a Christian people was a bitter one, and the cup for them has been bitter from that time to this. The facts attending Captain Cook's death, and the treatment of his remains, the Doctor received from the mouth of an honest old native named Keha, on the island of Maui, a clear-minded man, and one of the hereditary historians of the Kings or Chiefs. The natives always regretted Cook's death."

THE German Arctic Navigation Society of Hamburg city has received a telegram from Tromsöe, dated July 6, according to which eighteen Norwegians who had passed the winter in Spitzbergen, have been found dead by the society's schooner *Tromsöe*, Captain Mack. They have been buried by the latter's direction.

THE latest novelty in literature is a farthing daily paper, in the shape of *The Penny-a-Week County Daily Newspaper*, a single copy of which may be had for a farthing, but which, by a little arrangement, will be supplied to any subscriber for a penny a week. It is intended as an organ for sowing broadcast the principles of the Conservative party, who, if they really have the welfare of their country at heart, ought to make use of this splendid opportunity for elevating the classes whom they want to influence, by serving up a daily modicum of useful knowledge methodically arranged,—*i.e.* Science.

WE have received from A. Ernst his careful paper on the Meteorology of the Carácas, based on three years' observations by Señor Agustin Aveledo.

THE "Transactions of the Royal Society of Arts and Sciences of Mauritius" for 1871, which has just reached us, shows that that body is in excellent working order, and is quite alive to the interests of Science in that hybrid colony, especially in the department of Natural History. The curious mixture of French and English in the volume is significant of the history of the island and the mixed nationality of the colonists. The longest, and one of the most valuable and interesting papers in the volume, is Colonel Pike's account (in English) of a visit he paid to the Seychelle Islands, containing important details on the natural history of this remote and little-known group. The Society has been the means of successfully introducing into the Mauritius the cultivation of the silkworm, and an association has been formed for the manufacture of textile fabrics from native plants, especially from the *Agave*.

THE "Fourth Annual Report of the State Board of Health of Massachusetts," deserves the attention of all who are interested in the public welfare so far as sanitary matters are concerned. Detailed reports on all subjects connected with public health are given, and some humiliating and curious revelations made as to adulteration of food and drink, which seems to be nearly as universal in Massachusetts as in our own enlightened and very moral country; as is also ignorance of the use and preparation of food. Reports such as these show how lamentable and wide-spread is ignorance of the science of living, and with what a host of adverse influences in the way of adulteration, bad drainage, and such like, civilised man is surrounded.

WE have received Memoirs, by Prof. Asa Gray, of the late Mr. John Torrey and Mr. W. S. Sullivant, written for the American Academy of Arts and Sciences.

PART I. of vol. ix. of "The Journal of the Royal Agricultural Society of England and Wales," contains many statistics and papers of great value connected with the subject of Agriculture. Besides a variety of statistics as to grain, Cattle, Sheep, Pigs, Dairy Produce, Prices, &c., the Journal contains the following papers: On the Characters of Pure and Mixed Linseed-Cakes, by Dr. Augustus Voelcker, F.R.S.; Report of the Judges on the Trials of Portable Steam-Engines at Cardiff; Report of Experiments on the Growth of Barley for Twenty Years in succession on the same Land, by J. B. Lawes, F.R.S., and J. H. Gilbert, F.R.S.; Record of Rainfall at Rothamsted (parish of Harpenden) and Harpenden Village, near St. Alban's, Herts, in 1872 and the 19 preceding years; Report on the Trade in Animals, and its Influence on the spread of Foot-and-Mouth and other Contagious or Infectious Diseases which affect the Live Stock of the Farm, by H. M. Jenkins, F.G.S., Secretary of the Royal Agricultural Society; Further Report by the Judges on the Competition for Prizes for Plans of Labourers' Cottages in connection with the Cardiff Meeting, 1872; The Potato Disease, by William Carruthers, F.R.S., Consulting Botanist to the Society; On Dodder, by W. Carruthers, F.R.S.; Annual Report of the Consulting Chemist for 1871; Quarterly Report of the Chemical Committee, December, 1872; Quarterly Report of the Principal of the Royal Veterinary College.

THE death of Mr. J. A. Gordon, Superintendent of the Crystal Palace Gardens, is announced. Mr. Gordon was in part trained under Sir Joseph Paxton, and was well known as a contributor to the *Gardener's Magazine*.

MR. J. L. HADDEN, C.E., superintended the electric light arrangements on the occasion of the late *fêtes* at Constantinople for the Sultan's accession. The next morning on awaking he found himself quite blind. The medical men had hopes of his restoration to sight.

THE additions to the Zoological Society's Gardens during the past week include a Rock-hopper Penguin (*Eudyptes chrysocoma*), from the Falkland Islands, presented by Mr. J. M. Dean; a tuberculated Lizard (*Iguana tuberculata*), from the West Indies, presented by Mr. J. B. Spence; a Greater Sulphur-crested Cockatoo (*Cacatua galerita*), from Australia, presented by Mr. R. Dean; four black-necked Swans (*Cygnus nigricollis*) hatched in the Gardens; a Beaver (*Castor canadensis*), born in the Gardens; two crimson-faced Waxbills (*Pytelia melba*), from Africa; a Tawny Eagle (*Aquila naevioides*), purchased; a black-tailed Antelope (*Nanotragus nigricaudatus*), an Ariel Toucan (*Ramphastos ariel*), and a West India Rail (*Aramides Cayennensis*), deposited.

ON THE GERM THEORY OF PUTREFACTION AND OTHER FERMENTATIVE CHANGES.*

AFTER some introductory remarks referring to the various other theories which had been entertained on this subject, viz., the oxygen theory, the theory of spontaneous generation, and that of chemical ferments, the author stated that the researches of Pasteur had long since made him a convert to the germ theory, which attributes the alteration experienced by exposed organic substances to the development within them of minute organisms springing, like larger living beings, from parents like themselves; and that this belief had been since continually strengthened by the results of the antiseptic system of treatment in surgery, which he had founded on that theory as a basis.

But his attention had been afresh directed to the subject about a year and a half ago by a remarkable paper by Dr. Burdon-Sanderson,† in which experiments were recorded, leading to the conclusion that Bacteria, unlike the spores of fungi, are deprived of vitality by mere desiccation at a moderate temperature, so that while a drop of water from ordinary sources or the contact of a moist surface is sure to lead to Bacteric development and consequent putrefaction in an organic substance susceptible of that change, the access of dust from exposure to the atmosphere induces merely the growth of fungi and comparatively insignificant chemical alteration.

If this were true it would be needless to provide an antiseptic atmosphere in carrying out the antiseptic system of treatment; and all that would be requisite in the performance of a surgical operation would be to have the skin of the part about to be operated on treated once for all with an efficient antiseptic, while the hands of the surgeon and his assistants and also the instruments were similarly purified; a dressing being afterwards used to guard against the subsequent access of septic material. Thus the use of the spray might be dispensed with, and no one would rejoice more than himself in getting rid of that complication.

Such being the practical importance of the conclusion referred to, he determined to subject it to a searching experimental test.

The material first employed was urine, not boiled, as it had commonly been in previous investigations, but obtained, by a very simple antiseptic process, perfectly uncontaminated in its natural condition, in which it proved a far more favourable nidus for the development of organisms than in the boiled state, as indeed might have been anticipated, since it contains unaltered the complicated organic substance termed the mucus, which has been sometimes regarded as a chemical ferment of urine. Nevertheless, when a wine-glass, together with a small porcelain evaporating dish, to serve as a cover, had been heated, like the vessels used by Dr. Sanderson, far above the boiling-point of water, and allowed to cool (a process conveniently designated by the term "heated"), and afterwards charged with the unboiled urine, and placed under a glass shade as an additional protection against dust, it was found that the fluid remained free from organic development or putrefactive change for months, till at last it dried up into a saline mass. On the other hand, if a glass so charged was exposed to the air by removing the shade and cover for a while, organisms appeared in it of various kinds, and among the rest, in several instances, Bacteria. Thus it was shown on the one hand that Bacteria might arise from atmospheric exposure, and on the other hand that a porcelain cover and glass shade afforded absolute security against the introduction of organisms from without. If, therefore, the exposure of such a glass for a limited period chanced to lead to the introduction of any one organism unmixed with others, the opportunity was afforded of studying the behaviour of that organism, either in the same medium for a protracted period or in other media in similar glasses, inoculated by means of a heated pipette or glass rod. For it was found as a matter of experience that exposure for the few seconds or fractions of a second necessary for performing the inoculation or withdrawing a little fluid for examination did not involve any considerable risk of accidental contamination.

Early in the investigation it was ascertained that the putrefaction of urine might take place without the occurrence of Bacteria, in presence of minute granules in irregular groups, in such numbers as to make the liquid milky; their organic nature being clearly proved by fissiparous generation observed to take place in them, though in a different manner from that which is seen in Bacteria. To this form of organism the name "Granuligera" has been provisionally applied.

In one of the experiments related, two drops of water from the tap having been added to a glass of Pasteur's solution, the result was not in the first instance the general opalescence due to Bacteria in a liquid, but a deposit which proved to be a minute filamentous fungus producing abundant spores (conidia) on its branches. These spores after separation often produced young plants like their parents; but there were also seen in abundance precisely similar spores multiplying by pullulation like a Torula (to retain the old use of the name as applicable to organisms like the yeast plant).* And there were also present multitudes of more slender filaments which were seen to break up into Bacteria, while in several instances these filaments were observed springing from spores undistinguishable from those of the fungus.

The view that some filamentous fungi may give origin to both toruloid and Bacteric forms was soon afterwards confirmed by another experiment. † A "heated" wine-glass was taken into the open air during a drizzling rain, and the cover being lifted, some rain-drops were allowed to fall into it, after which uncontaminated urine was introduced. The result was the production of a pullulating delicate Torula, totally different from the yeast plant; forming a granular deposit on the sides of the glass, and an abundant scum, both in the urine and also in Pasteur's solution on repeated inoculations. Portions of both liquids containing this organism having been set aside under circumstances permitting only very slow evaporation, they were examined again eight months later, when a delicate filamentous fungus was found in both, bearing conidia resembling the cells of the Torula, while similar spores were seen multiplying by pullulation, and some of the buds were in a slender form undistinguishable in character from the Bacteria which in the case of the urine were observed swimming in the liquid.

An organism which in the first instance was observed for weeks together growing as a mere Torula having thus, as it appeared, developed into a filamentous fungus, after remaining for months in the same solution, hopes were excited that a corresponding observation might be made with regard to the yeast-plant, and this led to a careful examination of a low white mould, referable to the genus Oidium, which was observed in a glass of Pasteur's solution to which yeast had been added several weeks previously. The hope was disappointed, but some interesting facts were elicited: for the fungus was found to vary remarkably according to the quality of the medium in which it grew, having sometimes the aspect of an Oidium with fructifying filaments, sometimes a purely filamentous structure, sometimes a loosely-jointed growth producing abundant oval spores destitute of nuclei, and often pullulating like a Torula, and lastly a purely toruloid form of an entirely different aspect, composed of spherical nucleated cells, occurring in urine, and operating as a powerful putrefactive ferment upon that fluid. Yet totally dissimilar as the different forms of this fungus might appear, their identity was demonstrated by observing with the microscope the actual growth of one from another when transferred to a new medium on a slide of thick glass excavated round a central island, so as to provide a sufficient supply of oxygen to last the growing fungus for a long period. The slide and its thin covering glass were heated between metallic plates to diffuse the heat and prevent cracking of the glass, so arranged as to guard against the entrance of dust during cooling, and all instruments, such as forceps and needles, employed in the subsequent manipulations, were "heated" before being used, the thin covering glass being luted down with melted paraffin applied with a hot steel pen. "Glass gardens" of this construction stocked with various organisms in various media proved extremely useful means of investigation. Samples of the organism introduced were sketched with camera lucida immediately after introduction, and their subsequent development observed with perfect precision. In this way, in the case of the Oidium, spherical nucleated cells of

* Abstract of a communication made to the Royal Society of Edinburgh, April 7, 1873, by Prof. Joseph Lister, F.R.S.

† See 13th Report of the Medical Officer of the Privy Council.

* The toruloid pullulation of spores of some minute filamentous fungi had been previously observed by De Bary. *See* "Morphologie und Physiologie der Pilze," &c., von. Dr. A de Bary, p 183.

† This view has been expressed by various other authors, but has been hitherto incapable of demonstration in consequence of the uncertainty whether things which seem to grow from one organism may not be merely the result of the accidental presence of others.

the toruloid form of the organism were observed to sprout into beautiful filamentous fungi, and these again, as the fluid became vitiated by the growing fungus, were found to reproduce as conidia the spherical toruloid cells.

Among other media inoculated with this Oidium was a solution of albumen obtained by treating a fresh-laid egg with a solution of carbolic acid, to destroy any organisms adhering to the shell, and then breaking it with carbolised fingers into a "heated" vessel containing water that had been boiled and allowed to cool protected from dust, the solution being afterwards cleared by passing it through a boiled filter in a "heated" funnel with "heated" cover. This fluid had remained during the half-year which had since elapsed, free from putrefaction or any other change, except where organisms had been introduced, although the air had free access to it; * a fact which indicates pretty clearly that the putrefaction of eggs, which has been regarded as a stumbling-block in the way of the germ theory, must somehow or other be brought about by the penetration of ferments through the shell and membrane. This, indeed, becomes intelligible enough if we admit that Bacteria may be formed from fungi, and remember how the filaments of some parasitic fungi perforate the epidermis of leaves.† In a glass of this albuminous fluid the Oidium grew very slowly and feebly, but its development was accompanied by a remarkable alteration in the liquid, which, in the course of six weeks, changed from the colourless purity of spring water to the dark brown, almost black, appearance of porter. Yet the dark brown liquid remained perfectly free from smell, proving, what the author had long suspected as the result of experience in antiseptic surgery, that an albuminous fluid may undergo fermentation with odourless products.

Another experiment given in full detail was performed with milk upon the same principle as those with urine and albumen, in the hope of removing another stumbling-block in the path of the germ theory. For, according to the high authority of Pasteur, milk forms an exception to organic liquids in general, in the circumstance that a greater elevation of temperature than the boiling-point of water is required to kill Bacteria contained in it.‡ But the advocates of the theory of spontaneous generation reply that any Bacteria present would be certainly killed by boiling, and therefore the subsequent appearance of living Bacteria in the boiled milk in Pasteur's experiments is proof of their spontaneous evolution from the chemical constituents of the liquid. If, however, by the use of antiseptic means, milk could be obtained uncontaminated from the cow, there being no organisms to kill, boiling might be dispensed with, and the milk, like the unboiled urine, should remain free from organic development or fermentative change, if kept protected in "heated" vessels. Accordingly, five flasks with glass caps, and six test-tubes with wider test-tubes to cover them, having been heated, and allowed to cool under glass shades in the stable where the experiment was performed, the udder and adjacent skin of a cow were well washed with a strong watery solution of carbolic acid, which was also applied with a small syringe to the outlets of the milk ducts, the teat being held in the finger and thumb to prevent the entrance of the solution into the udder, and a milkman with his sleeves tucked up, and his hands and arms washed with the antiseptic lotion, was directed to milk into the glasses as their covers were successively raised. The cow did not give milk at all freely, and a considerable time was occupied in charging the flasks, but the small quantity required for each test-tube was got by a single squirt from the teat, with almost momentary exposure. Yet not only in all the flasks but in all but one of the test-tubes organisms made their appearance. In one of the test-tubes, however, the unboiled milk had hitherto (for a quarter of a year) remained entirely unaltered. One such success was as clear evidence against the hypothesis of spontaneous evolution of organisms as if all the glasses had remained free from them, and their occurrence in the other ten proved a most fortunate circumstance. For no two of them were alike in the organisms they contained, and in several instances there was apparently only some one species unmixed with others, so that the opportunity was afforded of studying various different organisms as modified by other media, and as regards any fermentative influence which they might exert upon those media. Among the organisms in the milk glasses were Bacteria of different species, to judge from their size and other appearances, as well as numerous kinds of fungi; and when they were introduced into a series of glasses of the albuminous liquid before described, it was found that while some of the fungi grew in it others refused to do so, and while Bacteria obtained by adding a drop of water to urine throve in the albuminous fluid, not one of four inoculations of Bacteria from four milk glasses was followed by any result. Thus was afforded, it is believed, for the first time, distinct physiological proof of real differences among Bacteria. But what was still more unexpected was the fact that when the inoculation was practised in a series of glasses of urine, two of the Bacteria refused to grow even in that liquid, which had been previously regarded as a peculiarly favourable nidus for Bacteric development. This fact, besides serving still more clearly to differentiate the various species of Bacteria, suggested a possible explanation of the failure of experiments with milk in the hands of others. For if organisms thrive in milk which cannot grow in urine at all, milk must be a more difficult fluid to work with in experiments which aim at excluding organic development. Hence it seemed worth while to try again the effect of boiling milk, but in doing so to adopt more rigorous precautions against the entrance of organic germs. There could be little doubt that the organisms which appeared in the various milk glasses of the experiment above related entered during the cooling, which though it took place just as in the successful experiments with urine, led to failure in the case of the milk, partly from the favourable nature of that liquid for organic development, and partly no doubt from the atmosphere of the stable being much more loaded with organic germs than that of the author's study. The new precautions adopted were in the main these. The small wine glasses (liqueur glasses) into which the fluid was to be decanted were covered, together with their glass caps, while still very hot, with cotton wool secured by fine iron wire tied tightly round below the cap, so as effectually to filter the air that entered during cooling; after which the cotton was carefully removed and the glass placed under a small glass shade on a separate piece of plate glass. For heating the flask in which the milk was to be boiled a very high temperature was requisite to ensure destruction of all life in the considerable volume of air which it contained; and this was arranged for by binding asbestos with wire round the junction of the neck of the flask and the glass cap, and then roasting the flask over a large Bunsen's burner. The asbestos, which proved as good a filter as cotton wool, was removed after cooling, and the cap being lifted, a long "heated" funnel was passed quickly into the flask and the milk poured in through it after wrapping a piece of carbolised rag round the funnel and neck of the flask to exclude septic dust: scrupulous care being taken to avoid touching the neck of the flask with the moist end of the funnel as it was withdrawn. By this means security was obtained against the presence of any living organism inside the flask except in the fluid at the bottom of the vessel. The cap was then re-applied and carbolised cotton wool tied over it to filter regurgitant air during the boiling. The necessity for the air-filter was made very manifest during ebullition from the great tendency of milk to froth, involving the necessity of frequently removing the flame, fresh air entering on every such occasion: another peculiarity of milk which served further to explain the failure of previous experiments. But the efficiency of the means employed was shown by the appearance of the flask as exhibited to the Society. For although seven weeks had passed since it was filled, the milk was seen to be perfectly fluid and with no appearance of alteration.

All trouble occasioned by frothing, involving constant watching to prevent the froth from wetting the cotton, was afterwards avoided by acting on the suggestion of Mr. Godlee, of University College, London, who happened to be assisting the author at the time, and immersing the flask in boiling water above the level of the liquid, instead of applying the flame directly. This method had the further advantage of avoiding any risk of "burning" the milk, and also any loss by evaporation. A second flask "heated" and charged with milk like the other and similarly covered with cotton wool, was kept in this way at 212° F. for an hour, and, after cooling, its contents were decanted off into twelve "heated" liqueur glasses, and in these it had remained during the seven weeks that had since passed perfectly free from change except when organisms had been intentionally introduced. To illustrate this the author drank, before the Society, the contents of one of the uninoculated glasses, which proved perfectly sweet and good.

It was a curious circumstance that on the morning following

* Dr. Burdon-Sanderson had previously preserved unboiled white of egg unchanged for six months in a "heated" tube containing air, hermetically sealed.

† See De Bary, op. cit., page 216.

‡ See Annales de Chimie et de Physique, 1862, p. 60.

the night on which the liqueur glasses were thus charged with boiled milk, the author received from Dr. Roberts, of Manchester, a copy of his paper describing how he had got over all the difficulties, as regards milk, by a different and very simple method.* But beautiful as Dr. Roberts's method was, and perfectly conclusive against the theory of spontaneous evolution, it would not have answered the author's purpose, as it was essential for his investigations that the liquid should be decanted from the flask into the liqueur-glasses. The decanting was effected by means of a "heated" syphon, with special precautions against the entrance of living organisms, as was fully explained to the Society.

The same plan of "heating" the vessels and decanting was afterwards followed with turnip infusion and with urine; and in proof of the security of the method, flasks containing the residual stock of these fluids after decanting into twelve glasses from each nearly six weeks before, were shown to the Society quite unchanged. And as further evidence of the trustworthiness of the system pursued, it was mentioned that out of six series of wine-glasses with about twelve in each series, containing albuminous fluid, urine (in two series), Pasteur's solution, boiled milk and turnip infusion, although portions of the contents had been often removed for investigation or inoculation, only two instances were known to have occurred in which any organism (a filamentous fungus) had made its appearance which had not been arranged for either by inoculation or prolonged exposure.

(*To be continued.*)

SCIENTIFIC SERIALS

Ocean Highways for July is a very interesting number. The first article, on the "Voyage of the *Polaris*," accompanied by six small maps, shows that notwithstanding the disastrous results of Captain Hall's venture, it proves more strongly than ever that a well-equipped Arctic expedition, taking the route of Smith's Sound, would be attended with results of the highest value. "In the present day," the writer concludes, "when the true methods of exploring are well known, and men of science have clearly enumerated the important problems that will be solved, and the numerous valuable results that will be derived from the labours of an Arctic Expedition, the reasons for despatching one have acquired tenfold force." This is followed by a long and extremely valuable and interesting account of "Personal Experiences of Venomous Reptiles and Insects in South America," by Mr. Richard Spruce, who has spent fifteen years in Equatorial Africa for the purpose of investigating the natural history of that region. The author's account of his experiences gives a vivid idea of the many dangers and trials to which devotees of science are exposed, in their endeavours to add to the sum of human knowledge. We would strongly recommend Mr. Spruce's interesting article to all who take an interest in the subject, on which, our readers may remember, there was recently some correspondence in NATURE. H. H. Giglioli contributes two very valuable letters from Dr Beccari on his explorations in Papuasia, which are likely to be attended with very important results. Other papers in this number are "On Settlements on the Gold Coast," with a map; a paper on Khiva, by Rev. G. P. Badger, consisting of a catena of extracts from several eminent Arabic writers; the "Footpaths of London," a sort of popular geological lecture, by Mr. H. P. Malet; and the second part of Prof. H. Mohn's article on the Meteorological Institute of Norway.

Bulletin de la Société de Géographie, May. The first article in this journal is by M. Charles Maunoir, on the work of the French Geographical Society, and the Progress of the Geographical Sciences during the year 1872.—Mr. W. Huber contributes an interesting paper on the telegraphic network of the globe, with a map showing at a glance how much has already been done in this way to annihilate distance, and how much remains to be done to complete this important work.—This is followed by the conclusion of M. Balansa's paper on New Caledonia, the present instalment treating specially of the Loyalty Islands.—M. Edouard Sayons gives an abstract of the contents of M. Hunfalvy's very interesting work on the Finnish Provinces of the Baltic; the work is published in Hungarian, and is an account of the author's explorations in the districts mentioned in the year 1870.

* See NATURE, Feb. 20, 1873.

SOCIETIES AND ACADEMIES

Royal Society, June 19.—"On a newly discovered extinct Mammal from Patagonia (*Homalodotherium Cunninghami*)," by William Henry Flower, F.R.S., Hunterian Professor of Comparative Anatomy, and Conservator of the Museum of the Royal College of Surgeons.

The author describes the complete adult dentition of a new genus of Mammal, founded on remains discovered by Dr. Robert O. Cunningham in deposits of uncertain age, on the banks of the River Gallejos, South Patagonia. The animal appears to have possessed the complete typical number of teeth, *i.e.* twenty-two above and below, arranged in an unbroken series, and of nearly even height, and presenting a remarkable gradual transition in characters in both jaws, from the first incisor to the last molar. The molars more clearly resemble those of the genus *Rhinoceros* than any other known mammal; and, judging by the general characters of the teeth alone, the animal would appear to have been a very generalised type of Perissodactyle Ungulate, allied through *Hyracodon* (a North-American Miocene form) to *Rhinoceros*, also more remotely to *Macrauchenia*, and, though still more remotely, to the aberrant *Nesodon* and *Toxodon*. The generic name *Homalodotherium* was suggested for this form by Prof. Huxley in his Presidential Address to the Geological Society in 1870.

"The Diurnal Variations of the Wind and Barometric Pressure at Bombay," by F. Chambers. Communicated by Charles Chambers, F.R.S., Director of the Colaba Observatory, Bombay.

The object of this paper is to bring to notice a remarkable relation that has been found to exist between the diurnal variations of the wind and the barometer at Bombay.

The observations made use of are the records of a Robinson's anemograph during the first three years of its performance, viz. from June 1867 to May 1870, and the corresponding hourly observations of the barometer and the dry- and wet-bulb thermometer, made at the Government Observatory, Bombay.

The mean results for each hour of the day during the whole period, and the mean diurnal relations of each element are tabulated and graphically represented by figures. The diurnal variation of the wind is then investigated, the most influential part of which is attributed to the land- and sea-breezes which blow from E.S.E. and W.N.W., and are shown to follow mainly the same law of progression as the temperature of the air, thus affording confirmatory evidence of the truth of Hadley's theory of the trade-winds as applied to land- and sea-breezes.

Some peculiarities of the curve representing the land- and sea-breezes are then pointed out, and these the writer concludes are due to the superposition of another distinct variation having two maxima and two minima in the twenty-four hours like the barometer variation; and he supports his views by a reference to the variation of the east components of the wind in the months of July and August, when the land- and sea-breezes have almost disappeared. This is found to exhibit a decided *double* period. The north components of the land- and sea-breezes are then approximately eliminated from the north components of the whole variation, and the variation which then remains exhibits a very decided *double* period in this direction also. These variations with double periods are regarded as indicative of the existence of a double diurnal variation in the general movements of the atmosphere. Upon this hypothesis typical diurnal variations of the wind are deduced for north and south low latitudes; that for north latitudes exhibiting a double diurnal right-handed rotation, and that for south latitudes a double diurnal left-handed rotation, and from these the diurnal variation of the barometer is deduced.

The movements of the wind-vane at Bombay are then analysed, and the writer concludes that the greater part of the excess of "direct" over "retrograde" rotation of the vane at Bombay is due to the *diurnal variation* of the wind.

Extracts are given from observations made at St. Helena, Toronto, and Falmouth, showing the character of the diurnal wind-variations at those places, and their greater or less agreement with the deduced typical curves. The writer maintains that these variations afford independently a possible, if not a probable explanation of that movement of the air which Dové had called the "Law of Gyration;" and in conclusion he points to the extent of their applicability in deducing weather probabilities, and to the method of discussing storms.

A postscript is added, giving the mean diurnal variation of the wind at Sandwick Manse, Orkney, and pointing out its general conformity with the results deduced from the Bombay wind-observations.

"On the Mathematical Expression of Observations of Complex Periodical Phenomena, and on Planetary Influence on the Earth's Magnetism," by Charles Chambers, F.R.S. and F. Chambers.

"Observations of the Currents and Undercurrents of the Dardanelles and Bosphorus, made by Commander J. L. Wharton, of H.M. Surveying Ship *Shearwater*, between the months of June and October, 1872." From a Report of that Officer to the Hydrographer of the Admiralty. Communicated by Admiral Richards, C.B., V.P.R.S.

Geological Society, June 25.—Joseph Prestwich, F.R.S., vice-president, in the chair. The following communications were read:—"On six Lake-basins in Argyllshire," by his Grace the Duke of Argyll, F.R.S., president. The author referred to the part ascribed to glacial action in the formation of lake-basins, and described the basins of six lakes in Argyllshire, the characters presented by which seemed to him inconsistent with their having been excavated by ice. Among these lakes were Loch Fyne, Loch Awe, Loch Leckan, and the Dhu Loch.—"Description of the Skull of a dentigerous Bird (*Odontopteryx toliapicus*, Owen), from the London clay of Sheppey," by Prof. Richard Owen, F.R.S. The specimen described by the author consisted of the brain-case, with the basal portion of both jaws. The author described in detail the structure and relations of the various bones composing this skull, which is rendered especially remarkable by the denticulation of the alveolar margins of the jaws, to which its generic appellation refers. The denticulations, which are intrinsic parts of the bone bearing them, are of two sizes—the smaller ones about half a line in length, the larger ones from two to three lines. The latter are separated by several of the smaller denticles. All the denticles are of a triangular or compressed conical form, the larger ones resembling laniaries. Sections of the denticles show under the microscope the unmistakable characters of avian bone. The length of the skull behind the fronto-nasal suture is 2 inches 5 lines; and from the proportions of the fragment of the upper mandible preserved, the author concluded that the total length of the perfect skull could not be less than between 5 and 6 inches. The fossil seems to approach most nearly to the Anatidæ, in the near allies of which, the Goosanders and Mergansers, the beak is furnished with strong pointed denticulations. In these, however, the tooth-like processes belong to the horny bill only, and the author stated that the production of the alveolar margin into bony teeth is peculiar, so far as he knows, to *Odontopteryx*. He concluded, from the consideration of all its characters, "that *Odontopteryx* was a warm-blooded, feathered biped, with wings; and further, that it was web-footed and a fish-eater, and that in the catching of its slippery prey it was assisted by this pterosauroid armature of its jaws." In conclusion, the author indicated the characters separating *Odontopteryx* from the Cretaceous fossil skull lately described by Prof. O. C. Marsh, and which he affirms to have small, similar teeth implanted in distinct sockets.—"Contribution to the Anatomy of *Hypsilophodon Foxii*, an Account of recently acquired Remains of this Dinosaur," by J. W. Hulke, F.R.S. The author communicated details of its dentition, the form of its mandible, and that of the cones of the shoulder and fore limb, and of the haunch and hind limb, hitherto imperfectly or quite unknown. The resemblance to *Iguanodon* is greater than had been supposed, but the generic distinctness of *Hypsilophodon* holds good.—"On the Glacial Phenomena of the 'Long Island,' or Outer Hebrides," I., by James Geikie, F.R.S.E., of H.M. Geological Survey of Scotland. The author commenced by describing the physical features of Lewis, which he stated to be broken and mountainous in the south, whilst the north might be described as a great peat moss rising gradually to a height of about 400 ft., but with the rock breaking through here and there, and sometimes reaching a higher elevation. The north-east and north-west coasts are comparatively unbroken, but south of Aird Laimisheader in the west and Stornoway in the east, many inlets run far into the country. The island contains a great number of lakes of various sizes, which are most abundant in the southern mountain tract and in the undulating ground at its base. The greater part of Lewis consists of gneiss, the only other rocks met with being granite and red sandstone, and conglomerate of Cambrian age. The stratification of the gneissic rocks is generally well marked; the prevalent strike is N.E. and S.W. with S.E. dip, generally at a high angle. The author described in considerable detail the traces of glaciation observed in the lower northern part of Lewis, and inferred from his observations that the ice passed from sea to sea across the whole breadth of this district, and that it not only did not come from the mountainous tract to the south, but must have been of sufficient thickness to keep on its course towards the north-west undisturbed by the pressure of the glacier masses which must at the same time have filled the glens and valleys of that mountain region. After describing the characters presented by the bottom-hill in the northern part of Lewis, the author proceeded to notice those of the lakes, some of which trend north-east and south-west, while those of the mountain district follow no particular direction. The lake-basins of the first series he regarded as formed at the same time and by the same agency as the *roches moutonnées* and other marks of glacial action; they are true rock-basins or hollows between parallel banks wholly of till, or of till and rock. The N.E. and S.W. lakes coincide in direction precisely with the strike of the gneiss; and the author explained their origin by the deposition of till by the land-ice in passing over the escarpments of the gneiss facing the north-west. The lakes of the mountain district are regarded by the author as all produced by glacial erosion. The author considered that the ice which passed over the northern part of Lewis could only have come from the main land. Referring to the glaciation of Raasay, he showed that the ice-sheet which effected it must have had in the Inner Sound a depth of at least 2,700 ft., and taking this as approximately the thickness of the *mer de glace*, which flowed into the Minch, which is only between 50 and 60 fathoms in depth, no part of this ice could have floated, and the mass must have passed on over the sea-bottom just as if it had been a land surface. Ice coming from Sutherland must have prevented the flow of the Ross-shire ice through the Minch into the North Atlantic, and forced it over the low northern part of Lewis; and the height to which Lewis has been glaciated seems to show that the great ice-sheet continued its progress until it reached the edge of the 100-fathom plateau, 40 or 52 miles beyond the Outer Hebrides, and then gave off its icebergs in the deep waters of the Atlantic.—"Notes on the Glacial Phenomena of the Hebrides," by J. F. Campbell, F.G.S. The author stated that, on the whole, he was inclined to think that the last glacial period was marine, and that heavy ice came in from the ocean, the local conditions being like those of Labrador. The author regarded most of the lake-basins of the Hebrides as formed by ice-action, and considered that the ice by which those islands were glaciated came from Greenland.—"On Fossil Corals from the Eocene Formation of the West Indies," by Prof. P. Martin Duncan, F.R.S. The specimens were collected from limestone and coral conglomerates, which are covered by, and rest upon volcanic *débris* and ejectmenta in the island of St. Bartholomew. The determination of the forms of the associated Mollusca and Echinodermata permit the following deposits being placed on a general geological horizon—the limestone and conglomerate of St. Bartholomew, the dark shales beneath the Miocene of Jamaica, the beds of San Fernando, Trinidad. These were probably contemporaneous with the Java deposits, the Eocene of the Hala chain, the great reefs of the Castel Gomberto district, the reefs of Oberberg in Steiermark, and the Oligocene of Western Europe. The affinities and identities of the fossil forms with those of contemporaneous reefs in Asia and Europe, and the limitation of the species of the existing Caribbean coral fauna, point out the correctness of the views put forth by S. P. Woodward, Carrick Moore, and the author, concerning the upheaval of the isthmus of Panama after the termination of the Miocene period.—"Note on the Lignite-deposit of Lal-Lal, Victoria, Australia," by R. Etheridge, jun., F.G.S. The lignite is almost entirely composed of remains of coniferous plants not now existing in Victoria; and the author considered that it is nearly of the same age as the lignite deposit of Morrison's Diggings, which has been regarded as Miocene.

Entomological Society, July 7.—Henry T. Stainton, vice-president, in the chair. Mr. Weir exhibited specimens of *Agrotera nemoralis*, taken near Lewes.—Mr. McLachlan exhibited a remarkable instance of hermaphroditism in a specimen of a fly (one of the *Syrphidæ*) taken at Black Park.—Mr. Trovey Blackmore exhibited specimens of a gall found on oaks near Tangier, which were taken possession of for a habitation by a species of ant (*Crematogaster scutellaris*, Oliv.)—Mr. William Pryer exhibited some fine species of Lepidoptera from

China.—Sir S. S. Saunders communicated a paper "On the habits and economy of certain Hymenopterous Insects which nidificate in briars; and their parasites." The insects were exhibited at the last meeting, and Sir Sydney Saunders further exhibited a specimen of a *Raphiglossa*, which he had suffocated with cyanide of potassium, whilst asleep, showing the remarkable position of the insect during repose, as described in the paper.—Mr. Butler communicated a list of the species of *Galeodides*, with description of a new species in the British Museum.

PHILADELPHIA

American Philosophical Society, March 7.—Hector Orr made a communication on the microscopic slide of Mr. Holman.—Dr. Leiler exhibited a modification of apparatus for showing the vibration of molecules in light.—Prof. J. P. Lesley presented a map of the subterranean portions of the collieries of Wilkesbarre, Pennsylvania.—Prof. P. E. Chase read a paper on Planetaxis, the relation of the rotation of the sun and interior asteroids to the sun-spot period, and on the relative velocities of light and gravity.

March 21.—Prof. P. E. Chase pointed out the precise accordance of the wave-length of the Fraunhofer F line with the wave-length of the F note in the 26th musical octave. The other Fraunhofer lines also correspond very closely with the musical notes which are designated by corresponding letters. If this accordance indicates that the luminiferous æther is a material medium, it appears that Winnecke's estimate of the sun's distance is the most accurate of those that have been based on astronomical observations.—Prof. Persifor Fraser exhibited an apparatus for the better manipulation of the lime-light.—Mr. Holman exhibited a slide for the microscope, designed for the better observation of substances suspended in fluids, especially the different corpuscles of the blood. The slide contained two concavities on its face, which were connected by a groove, and covered by a thin plate of glass. It was highly sensitive to changes of temperature.—A resolution was adopted recommending the passage of a bill by the Legislature of Pennsylvania, inaugurating a new Geological Survey of the State.

April 4.—Prof. P. E. Chase showed that, by making the differences symmetrical at each extremity of the planetary series, the supposed failure of Bode's law in the case of Neptune was only apparent, and that it gave the rule a higher generality. He also gave two new planetary series, based, like his modification of Bode's law, on laws of oscillation. If the mean distance of Neptune be divided by successive powers of the ratio of a circumference to its diameter, the points of division will fall in alternate planetary orbits, Saturn, Asteroid, Earth, Mercury. The last term of this first series brings us to the orbital axis of the centres of gravity of the sun and Jupiter. The second series is in regular harmonic progression. Taking Jupiter's perihelion distance as the unit,

$$\tfrac{1}{3},\ \tfrac{1}{5},\ \tfrac{1}{7},\ \tfrac{1}{9},\ \tfrac{1}{11},\ \tfrac{1}{13},\ \tfrac{1}{15},$$

respectively designate orbital positions of Mars, Earth, Venus, ?, Mercury's aphelion, Mercury's mean, Mercury's perihelion. Saturn, Uranus, and Neptune are also in harmonic progression beyond Jupiter. If we express this spheral harmony by musical intervals, they are generally such as to produce chords between any two adjacent planetary positions. But where quarter tones occur, the discordant vibrations seem to have broken up or disturbed the tendencies to planetary aggregations, thus aiding in producing the asteroidal belt, giving Mars and Mercury their diminutive masses and great eccentricity, and obliterating the theoretical planet between Mercury and Venus.—Prof. W. C. Kerr, State Geologist of North Carolina, communicated a paper on Topography of the Earth's surface, as affected by the rotation on its axis. He pointed out that the rivers of southern and eastern North Carolina flowed towards the ocean in a south-easterly direction, and that their south-western banks are elevated and bluffy, while the north-eastern descend very gradually to the water. They flow through, yielding materials of the cretaceous and tertiary formations, and have apparently undergone change of location, in the course of which they have excavated their south-western banks.—Prof. Kerr exhibited some mathematical reasons why this change might have been effected by the earth's rotation.—Prof. E. D. Cope read a paper on the flat-clawed carnivora of Wyoming. This group embraced two genera, *Mesonyx* Cope, and *Synoplotherium* Cope, which bore some resemblance in dentition to *Hyaenodon*. In both the claws were broad, flat, and fissured above, and without projecting endinous insertion below, and hence little prehensile use. In *Mesonyx* the astragalus has two distal facets; in *Synoplotherium* the scaphoid and lunar bones were distinct. The genera were thought to be of aquatic habit.

PARIS

Academy of Sciences, June 30.—M. de Quatrefages, president, in the chair.—During the meeting the Academy proceeded to elect a Foreign Associate in the place of the late Baron Liebig. Sir Charles Wheatstone obtained 43 votes, M. d'Omalius d'Halloy, 2; Sir C. Wheatstone was therefore declared duly elected.—The following papers were read:—Reflexions on Lagrange's memoir on the problem of three bodies, by M. J. A. Serret.—A comparison of the refraction indices of several isomeric compound ethers, by MM. Pierre and Puchot. The authors have found these indices sensibly the same when calculated for temperatures equally distant from the respective boiling points of the bodies in question.—On the analytical theory of the satellites of Jupiter, by M. Souillart.—Researches on the reflexion of solar heat at the surface of Lake Leman, by M. L. Dufour.—On the transplantation of the marrow of bones in sub-periosteum amputations, by M. Félizet.—New observations concerning the presence of magnesium round the entire disc of the sun, by M. Tacchini.—On the want of agreement between the old theory of the thrust (*poussée*) of earth and experiment, by M. J. Curie. This was a paper dealing with fortification.—Note on magnetism, by M. J. M. Gaugain.—On the cooling and freezing of alcoholic liquids and wines, by M. Melsens.—On the decomposition of metallic carbonates by heat, by M. L. Joulin.—On the calculus of the moments of inertia of molecules, by M. G. Hinrichs.—On the production of glycerin starting from propylene, by MM. Friedel and Silva.—On a glycerin of the aromatic series, by M. E. Grimaux.—On the estimation of sugar by Barreswil's method, by M. Loiseau.—Erythrophenic acid, new reaction of phenol and aniline, by M. Jacquemin.—On crystallised mercurous iodide, by M. P. Yvon.—A summary of the state of silk culture in 1873, by M. E. Guérin-Méneville.

THE PAY OF SCIENTIFIC MEN

THERE are a good many points of interest attaching to the Parliamentary paper referring to the pay of the officers of the British Museum, which, thanks to Lord George Hamilton, has been issued during this week.

It shows in a striking manner what the Government thinks of Science and its votaries; nor is this all: it shows in a not less striking manner how it behoves men of Science, if they consider that there should be a career for Science at all, to at once take some action, in order that their real claims may be conceded. Mr. Lowe, in defending not long ago the high rate of pay of Treasury clerks, who "begin" at 250*l.* a year and rise quickly to 1,200*l.* (if they are unfortunate enough not to get a staff appointment with much higher pay, long before they would, in the ordinary course of promotion, reach the senior class), stated that what was principally wanted at the Treasury, over and above the ordinary qualities of a clerk, was a certain "freemasonry," which was best got at the public schools. For this "freemasonry" Mr. Lowe is willing to pay 150*l.* a year over and above the 100*l.* which is the usual commencing pay of a junior clerk in the other Crown offices.

Perhaps it is too much to say that this "Freemasonry" is required in the British Museum. But there is certainly something required in the case of the scientific appointments there, of as special a character; and that is a knowledge of Science.

What then does Mr. Lowe do to secure this specialty? He gives the man of Science who enters the Museum the magnificent sum of 90*l.* per annum on entrance, with the still more magnificent—but, unfortunately, very distant—prospect of attaining an income of 600*l.* So that:—

Public School Freemasonry : Scientific Attainments : : 250*l.* : 90*l.*

This state of things has recently been brought home to the Trustees by petitions from all grades in the Museum, and a sub-committee of the Trustees has reported that, "owing to the insufficiency of the salaries, the slowness of their progressive rise, and the lowness of their maximum, the trustees are losing, and will continue to lose, their best men."

As a result of this report, in which we consider that higher ground might have been taken, the Trustees have proposed a new scale to the Treasury, the only fault of which is that—with the exception of the case of principal Librarian, who is not a specialist, who has no special work to do which could not be done by the keepers acting in turn as Dean, and who already has just double the salary of the most highly-paid keeper—it is far too modest. As the *Daily News* has well put it, a maximum of 500*l.* is "certainly not a too lavish position for a man who must be a scholar and linguist, an archæologist, natualist, or chemist, and must in most cases be already in middle life."

The men upon whose heads, hands, reputation, and work the success and fame of the Museum depend, are the keepers, whose pay, even as revised, is a mere pittance for such service as they render.

Altogether, the eventual *total* increased annual expenditure would amount to 5,700*l.* a year—the pay of *one* political or legal placeman, who has properly employed his "Freemasonry."

Here is the Treasury reply:—

"Treasury Chambers, March 28, 1873

"My Lords and Gentlemen,—The Lords Commissioners of Her Majesty's Treasury have had before them two letters from Mr. Winter Jones, dated the 4th instant, submitting recommendations for the grant of increase of salary to the principal Librarian and Secretary, and to various other officers of your establishment, and they desire me to say that, after giving their most careful consideration to all the statements put before them, they regret that they would not feel warranted in acceding to any alteration in the present scale of salaries.

"I have, &c.

(Signed) "WILLIAM LAW"

We trust that some determined stand will be made by the Trustees—among whom is the Right Hon. Robert Lowe—against this monstrous letter; and we trust also that some general protest will be made by men of Science and Culture generally against this latest valuation of these acquirements by the Government.

The man of Science serves his country as well as the politician, the lawyer, the soldier, or the sailor, although perhaps his claims are not stated in so blatant a manner, nor are at present so generally acknowledged, whether they will be in the future must to a large extent depend upon men of Science themselves: but whether this be conceded or not, surely in a country where the State remuneration for services performed is extraordinarily high in the upper appointments, our scientific chiefs in the public service should at all events receive the means of a decent livelihood, and such men as are employed in the British Museum, many of whom have world-wide reputations, should at least be treated as well as Government clerks.

Surely this is not to ask too much? Nay, it is already conceded by the Government in many departments where special scientific knowledge is required of no higher order than that which is so shabbily treated in the one Institution of which we have the greatest reason to be proud.

THE "POLARIS" ARCTIC EXPEDITION

WE have just received the printed Report, presented to the President of the United States by the naval authorities, of the result of their examination of those of the crew of the *Polaris*, who, in October last, were severed from that ship, and drifted on an ice-floe from about 80° north latitude during the whole of the winter until, 600 miles south from their starting-point, they were picked up on April 30, of this year, by the *Tigress* off the coast of Labrador. The Report furnishes material for one more of those thrilling narratives of Arctic adventure, which will be the delight of the boyhood of all generations, and which, commencing in the 10th century with that of Bjorne the Norseman, have been accumulating in increasing proportion, and will never fail to be added to until not a shred of mystery remains to unravel within the Arctic circle. The advocates of Arctic exploration by way of Smith's Sound, needed

only the narrative furnished in this Report, to render their arguments invincible.

The *Polaris*, an ordinary wooden vessel, left New London, Connecticut, on July 3, 1871, well furnished with provisions, but otherwise ill fitted for an Arctic expedition, under the command of Captain Hall, an enthusiastic explorer, who firmly believed he was "born to discover the pole," but apparently deficient in the firmness and decision necessary to manage a crew amid the trials of an Arctic winter; the officers and crew, moreover, seem to have been collected at haphazard, and were by no means well assorted. The second in command, Captain Buddington, who has now the command of the *Polaris*, ought never to have been taken on such an expedition, and, even though the most lenient construction be put upon his conduct, is deserving of the severest reprehension. After a delay of a week at St. John's, Newfoundland, the *Polaris* sailed for the West Coast of Greenland, and after calling at several places on that coast, arrived at Disco, which she left on August 17. After calling at the settlements of Upernavik and Tessiusak, the latter in 73° 24′ north lat., the *Polaris* commenced her exploring work in earnest, leaving Tessiusak on the 24th August. Hitherto there had been no difficulty whatever in navigation, nor was the vessel destined to meet with any obstruction until passing through Smith's Sound and Kennedy Channel, she reached 82° 16′ N. lat., a point far beyond the limits of previous navigation. This she did on August 30, within a week after leaving Tessiusak. After making unsuccessful efforts to find a way through the ice, Captain Hall resolved to return and take up winter quarters, which he did on September 3, in a small sheltered cove or bend of the coast in what he called Polaris Bay, the "Open Polar Sea" of Kane, where the ship was protected by a stranded iceberg—Providence Berg. This was in 81° 38 N. lat., 61° 44′ W. long. Had the vessel been specially built for Arctic exploration, it appears to us that Captain Hall by good management could have pushed even farther north before requiring to return to winter-quarters: as it is this is one of the most wonderful and successful Arctic cruises on record, considering the distance accomplished in less than a week so far within the ice-bound region. It affords the strongest ground for hope that with a vessel specially fitted for ice-navigation, a skilful captain may ere long complete the 8° that remain to be traversed before the North Pole be brought within the sphere of the known.

From Polaris Bay on October 10 Captain Hall left the *Polaris*, accompanied by Mr. Chester, first mate, and Hans the Esquimaux with two sledges and fourteen dogs. In the progress of the journey he discovered, as appears by his despatch, a river, a lake, and a large inlet. The latter, in latitude 81° 57′ north, he named "Newman's Bay," calling its northern point "Cape Brevoort," and the southern one "Sumner Headland."

Captain Hall, it appears, had hoped, when he left the *Polaris* on this journey, to advance northward at least a hundred miles; but after having gone about fifty he was compelled, by the condition of the shore and of the ice, and by the state of the climate, to return and await the approach of spring for another attempt. He reached the ship on October 24, apparently in his usual fine health, but was attacked the same day with sickness, and, taking to his bed, the next day was found to be seriously ill. After rallying once or twice he died on November 8, and was buried on the shore. The commissioners who examined the crew reach the unanimous conclusion that the death of Captain Hall resulted naturally from disease, without fault on the part of anyone. After this sad event, the command of the expedition devolved upon Captain Buddington, who expressly declared, according to the evidence, that he had no inclination and no intention to pursue discovery further; he determined to make his way south to the United States as soon as the ice would permit. During the winter little was done, and on August 12, 1872, the *Polaris* began to move southwards. On the 16th of August the ship was made fast to a large floe of ice in the latitude of 80° 2′ north, and longitude about 68° west, and while still fast to this floe drifted south through Smith's Sound nearly to Northumberland Island. On the night of the 15th of October, 1872, in about latitude 79° 35′ north, during a violent gale of wind and snow, the ship was suddenly beset by a tremendous pressure of ice, which was driven against her from the southward and forced under her, pressing her up out of the water, and by successive and violent shocks finally throwing her over on her beam-ends. In the words of the Report,—

Captain Buddington directed the provisions, stores, and materials which had been put in readiness on deck, to be thrown over on the ice, and ordered half the crew upon the ice to carry them upon a thicker part to the hummocks, where they would be comparatively safe. He also sent all the Esquimaux, with their kyaks, out of the ship, and lowered the two remaining boats upon the floe. While so engaged, in the darkness of an Arctic night, in the midst of a fierce gale and driving snow-storm, the hawsers of the *Polaris* failed to hold her, and she broke adrift from the floe, and in a few minutes was out of sight of the party who were at that moment busily at work on the ice.

From October 15, 1872, until April 20, 1873, when they were picked up in latitude about 59° north, these nineteen men, women, and children remained through the whole of the dark and dreary winter upon the ice. In their first endeavours to reach the land, they occupied for a time different pieces of floating ice, but, forced finally to abandon all hope in this direction, they rested at last upon the floe upon which the *Polaris* had made fast.

At the time of their separation from the *Polaris* every one belonging to the expedition was in good health. She had plenty of provisions, but not much coal—probably about enough to last through the winter. She was last seen, apparently at anchor, under Northumberland Island, where it is most likely she remained for winter-quarters.

Mr. Robeson has already given preparatory orders to the United States steamer *Juniata*, now at New York, to proceed, at the earliest practicable moment, to Disco, and if possible to Upernavik, for the purpose of carrying forward the necessary coal and supplies, communicating with the authorities of Greenland, obtaining information, and, if practicable, sending forward some word of encouragement to those on board the *Polaris*. This last will most likely be impossible, but an attempt will be made.

It is also proposed to fit out at once an expedition of relief, to be sent to Northumberland Island, where the *Polaris* was last seen, in the *Tigress*, about 200 tons

burden, built and fitted to contend with the ice, and the same ship by which the nineteen persons were rescued.

The following, in the words of the Report are a brief summary of some of the scientific results of the ill-managed expedition :—

While the records of the astronomical, meteorological, magnetic, tidal, and other physical departments of the exploration appear to have been extremely full, and the observations in each appear to have been conducted according to approved methods, the collections of natural history are shown to have been not less extensive, the store-rooms of the *Polaris* being filled with skins and skeletons of musk-oxen, bears, and other mammals ; different species of birds and their eggs : numerous marine invertebrata ; plants, both recent and fossil, minerals, &c. Not the least interesting of these collections are specimens of driftwood picked up on or near the shores of Newman's and Polaris Bays, among which Mr. Meyer thought he recognised distinctly the walnut, the ash, and the pine. Among the numerous facts that appear to be shown by the testimony elicited on the examination, we may mention as one of much interest that the dip of the needle amounted to 45°, and its deviation to 96°, being less than at Port Foulke and Rensselaer Harbour, as given by Dr. Kane and Dr. Hays. Auroras were frequent, but by no means brilliant, generally quite light, and consisting sometimes of one arch and sometimes of several. Streamers were quite rare. Shooting-stars were so constantly seen that, although no special shower was observed, it was scarcely possible ever to look at the star-lit sky without noticing them in one direction or another. The rise and fall of the tides were carefully observed, the average being about five and a half feet. The greatest depth of water noticed was about 100 fathoms. The existence of a constant current southward was noted by the expedition, its rapidity varying with the season and locality. The winter temperature was found to be much milder than was expected, the minimum being 58° in January, although March proved to be the coldest month.

The prevailing winds were from the north-east, although there were occasionally violent tempests from the south-west. Light winds were noticed, however, from all points of the compass. Rain was occasionally observed, only on the land, however, the precipitation presenting itself over the ice in the form of snow. During the summer the entire extent of both low lands and elevations are bare of both snow and ice, excepting patches here and there in the shape of the rocks. The soil, during this period, was covered with a more or less dense vegetation of moss, with which several arctic plants were interspersed, some of them of considerable beauty, but entirely without scent, and many small willows scarcely reaching the dignity of shrubs. The rocks noticed were of a schistose or slaty nature, and in some instances contained fossil plants, specimens of which were collected. Distinct evidence of former glaciers were seen in localities now bare of ice, these indications consisting in the occurrence of terminal and lateral moraines.

Animal life was found to abound, musk-oxen being shot at intervals throughout the winter.

Wolves, also bears, foxes, lemmings, and other mammals, were repeatedly observed. Geese, ducks, and other water-fowls, including plover and other wading-birds, abounded during the summer, although the species of land-birds were comparatively few, including, however, as might have been expected, large numbers of ptarmigan or snow-partridge. No fish were seen, although the net and line were frequently called into play in the attempt to obtain them. The waters, however, were found filled to an extraordinary degree with marine invertebrata, including jelly-fish and shrimps. Seals are very abundant. Numerous insects were observed, also, especially several species of butterflies, specimens of which were collected ; also, flies and bees and insects of like character.

The geographical results of the expedition, of which the accompanying map will give a good idea, so far as they can now be ascertained from the testimony of Messrs.

Diagram of the Explorations of the *Polaris*. (Drawn by F. Meyer, Signal Service, U.S.A.)

Tyson, Meyer, and their comrades, may be summed up briefly as follows :—

The open polar sea laid down by Kane and Hayes is found to be in reality a sound of considerable extent,

formed by the somewhat abrupt expansion of Kennedy's Channel to the northward, and broken by Lady Franklin's Bay on the west, and on the east by a large inlet or fiord, twenty-two miles wide at the opening, and certainly extending far inland to the south-east. Its length was not ascertained, and Mr. Meyer thinks that it may be, in fact, a strait extending till it communicates with the Francis Joseph Sound of the Germania and Hansa expedition, and with it defining the northern limits of Greenland. This inlet was called the Southern Fiord. North of it, on the same side, is the indentation of the shore called Polaris Bay by Captain Hall.

From Cape Lupton the land trends to the north-east, and forms the eastern shore of a new channel from twenty-five to thirty miles wide, opening out of the sound above mentioned, to which Captain Hall gave the name of Robeson Straits. North-east of Cape Lupton, in lat. 81° 57′, is a deep inlet, which Captain Hall called Newman's Bay, naming its northern point Cape Brevoort, and its southern bluff Sumner Headland. From Cape Brevoort the north-east trend of the land continues to Repulse Harbour, in lat. 82° 9′ north—the highest northern position reached by land during this expedition.

From an elevation of 1,700 ft. at Repulse Harbour, on the east coast of Robeson Straits, the land continues north-east to the end of those straits, and thence east and south-east till lost in the distance, its vanishing point bearing south of east from the place of observation.

No other land was visible to the north-east, but land was seen on the west coast, extending northward as far as the eye could reach, and apparently terminating in a headland and near latitude 84° north.

Mr. Meyer also states that directly to the north he observed, on a bright day, from the elevation mentioned, a line of light apparently circular in form, which was thought by other observers to be land, but which he supposed to indicate open water.

Of course the full scientific results of the *Polaris* expedition cannot be known until that vessel shall have been found and brought back with the treasures she has gathered, and the records and details of her Arctic explorations. But enough is told by the witnesses whom we have examined to excite expectation and encourage the hope of large and valuable additions to the domain of human knowledge.

Enough has been said to show that the way to the North Pole is clear and practicable: it remains for Britain to consummate the glory she has already acquired by sending out an expedition so equipped that it cannot fail to return with the solution of the Arctic mystery, whose bourne is being pushed further and further back every year. We would recommend the Report to the Joint Committee of the Royal and Geographical Societies now considering the subject of an Arctic Expedition.

SCIENCE AND ANGLING

Flies and Fly Fishing, with Hints on Minnow and Grasshopper Fishing. By Capt. St. John Dick. (Hardwicke.)

IT is doubtful whether much real progress has been made in the art of angling since the time of Walton, whose "Complete Angler" was published in 1653. A great improvement has taken place in fishing-tackle and implements, and we have much better rods, reels, lines, and lures now, than could have been got in old Isaac's time. Of late years the number of rod-fishers has enormously increased, and there is quite a plethora of popular treatises on the art of fishing. But in all the books we have seen, including the one whose title is at the head of this notice, there is a striking absence of any guiding principles to go by; and notwithstanding the marked improvement in the mechanical appliances referred to, and the increased number and activity of anglers, we repeat that it may be fairly doubted whether the latter are more successful fishers than their representatives 200 years ago. The cause of this is probably owing to the fact that hitherto attention has been almost exclusively directed to the mere practice of the art, and that angling as a science has been all but completely ignored. We have *ad nauseam*, empiric and dogmatic rules for the guidance of the tyro, but few of these are based on sufficient data, and most of them are quite untrustworthy. There is no statement for example, more frequently made in books on angling than that if the wind be from the east trout will not rise to the fly; and yet there are lakes (notably Loch Leven, Kinross-shire, probably the best trouting lake in Great Britain), in which the fish take best when the wind blows from that quarter. Another generally accepted canon is that fish will not rise freely during a thunderstorm, or when "there is thunder in the air;" but in our own not very large experience, we have again and again proved the falsity of this rule. It would be easy to multiply examples of the worthlessness of such empiric directions. What is wanted is a scientific treatise on angling. A principle in Science, some one has said, is a rule in art; and it is such rules that are desiderated. The object of this paper is rather to indicate this want than to supply it; and we have little hopes of much progress being made in the "gentle art" until it is carefully studied and treated scientifically. Until this is done there are many difficult problems connected with angling which must, we fear, remain unsolved. One day, for example, fish will take greedily any fly that is offered them, for an hour or two; and before or after this, their feeding time, the most skilful angler will practise all his wiles in vain. Another day, only flies of a particular colour or shape have any chance of taking. Again, it does happen occasionally that a veteran Waltonian will return from his favourite stream or lake, under the most auspicious influences of sky, wind, and water, with a very light basket, or it may be, an empty one. It is also a fact that the most successful day's fishing is sometimes achieved by going dead against all recognised rules and imitations of Nature. These are only a few of the things that require to be explained, and in the explanation of which a careful study of the nature and habits of fishes—how they are affected by atmospheric influences, &c.—would probably greatly assist. Of course, there are scientific anglers who have picked up their science under difficulties, and as they best could; and their number might be indefinitely increased if greater facilities were afforded for acquiring scientific knowledge. Such anglers will be sure to have the indispensable qualities of patience and perseverance; but they must also be careful observers of Nature, of the conditions of the water, of the appearance of the sky, and of meteorological phenomena in general; and in addition to all these they will be found to possess an intimate acquaintance with some special branch of Natural History.

There is a point connected with angling which is raised by Captain Dick, but not for the first time, and which demands investigation. It seems to be beyond question that, over the whole of Great Britain, trout are every year becoming scarcer. It is very seldom that the angler now-a-days makes a basket equal to what would have been called a very common take a score of years ago. So alarming has been this decrease that district associations are being formed for the purpose of watching and protecting the spawning grounds in their neighbourhood. The falling off is probably due to a variety of causes, such as over-fishing, pollution of streams, want of protection of spawning fish and spawning beds, the prevalence of pike, &c. It is certain that many streams and lakes, easy of access to populous districts, suffer from being over-fished; but the example of Loch Leven, already referred to, shows what may be done if proper precautions be taken. This lake is only 3½ miles by 2½, and 9 miles in circuit, and is open to anglers from all quarters (by paying a certain sum per hour) during the four months May, June, July, and August. The rest of the year the lake is closed, and the spawning grounds are carefully watched. There are both pike and perch in the lake, but nets are freely used to keep down these marauders. The results of these measures are worthy of notice. For the last fifteen years the takes have been gradually increasing, and last year upwards of 17,000 trout were taken by the rod. During the months of May and June this year nearly 9,000 have been taken, and it may be added that the average weight of Loch Leven trout is a little under 1 lb. What has been done by private enterprise for this lake might and should be done by Government for all the lakes and rivers in the country. There is no reason, that we know of, why there should not be a close time for trout as well as for salmon. The pollution of rivers by public works is a more difficult question to deal with; but surely something could be done to prevent such wholesale destruction as that, for example, which took place in the first week of July this year in the rivers Teviot and Ribble. In the former of these rivers tens of thousands of fish, including trout, smelt, grayling, and even salmon, were poisoned in one day. Unless some action be taken by Government strictly prohibiting manufacturers from sending their poisonous refuse into our rivers, not only will the fish in these soon become extinct, but the rivers themselves thus impregnated will act as open sewers generating and propagating disease in every direction. With a little judicious legislation, the quantity of fish obtained in fresh water might be so largely increased as to become important as an item of food for the people. We have indicated how this might be done with regard to trout, &c. With regard to salmon, all that is necessary to do is to blast the rocks at the Falls of the Tummel, the Gary, and the Spean, in Scotland, and of the Axe, and other rivers in England, and the area of the spawning grounds of this monarch of our rivers would at once be doubled. This could be done at little expense, due allowance being of course made for vested rights and any interests involved.

A single glance at any page of Captain Dick's book is sufficient to show that he is more accustomed to wield the rod than the pen; indeed we fail to see the *raison d'être* of the gallant captain's work. He has, it is true, mentioned one or two things worth setting down in an article or essay, but not worth writing a book about. His list of artificial flies is very full and may be of service. The only contribution to Natural History we can find is his statement—which we are inclined to accept as fact—that "although fish generally lie with their heads pointing up stream, they never, by any chance, take a fly in that position, but always make a decided turn in the act of rising, and take the fly with their heads pointing down stream." He adduces this as a reason for fishing down stream, of which practice, in opposition to the best anglers, he is a strenuous advocate. As to fishing with minnows, he prefers the ordinary metal kill-devils to natural minnows and to all other imitations. In this, also, experienced anglers will generally disagree with him. There is no lure more deadly for large trout, in certain seasons, than the natural minnow, and next after that, we should say, is the phantom minnow. In his remarks on pike-fishing, the author does not refer to the spoon-bait, which nevertheless, in lakes, especially in dull weather, may safely be backed against any other lure. Why does the author almost always use the word "fisherman," and only once the much more precise term "angler"? Strictly speaking, "fisherman" is a generic term, and applies equally to net and rod-fishers, but by common usage is generally employed to denote the former; whereas "angler" is a distinctive term which can be applied only to the rod-fisher.

MIVART'S "ELEMENTARY ANATOMY"

Lessons in Elementary Anatomy. By St. George Mivart, F.R.S. Pp. 535. (Macmillan, 1873.)

THIS modest volume is one of the series to which Huxley's "Physiology," Oliver's "Botany," and Roscoe's "Chemistry" belong. Like them it has the indispensable merit of being an elementary manual written by a master of the subject; for while special investigations may be often well performed by advanced students, primers and text-books can only be properly written by experienced teachers.

The plan of the book is to describe in a popular manner the various bones and other parts of human anatomy, excepting the reproductive organs, and then to point out the chief variations among other vertebrata. It would perhaps have been better to have called it "Elementary Lessons in the Comparative Anatomy of Vertebrate Animals:" for as all the organs are used to illustrate those of man, consideration of non-vertebrate classes is very reasonably omitted. Moreover, for reasons given in the preface, with which every teacher of the subject will probably agree, the largest space is given to the account of the endoskeleton. The whole forms a collection of facts, accurate in detail, carefully arranged, and clearly described. One would think there must be slips among so many isolated statements, but we have failed to detect one in a careful perusal of about 300 pages. The sixth chapter contains a review of the general morphology of the vertebrate skeleton, and here Mr. Mivart's well-known views, communicated to the Linnæan and Zoological Societies, are expounded fully but simply. Without admitting all his positions, as for example the

homology of the *trabeculæ cranii*, most of what is stated in this chapter is well enough established to form part of a manual for students of comparative anatomy.

But who are these students? No one could follow the closely printed pages of description here given, without a good general acquaintance with human anatomy and a thorough knowledge of the human skeleton. For this reason we think it would have been better to have curtailed or even omitted the preliminary accounts of each organ in man, because they are not sufficient alone, and there are many excellent treatises on this subject already. If it is answered that the book is really intended for boys and girls at school, then the details given, especially in osteology, are far too numerous: in fact they would be unintelligible without a good museum, and learning zygosphenes and hypapophyses without seeing them is far worse mental training than *Barbara Celarent*, or the verbs in -μι. For the second class of readers mentioned in the preface, teachers, medical students, and others acquainted with human anatomy, this little treatise will be found just what they want in order to learn "its more significant relations to the structure of other animals." The only defect they will find is the omission of the organs of reproduction and the structure of the ovum.

The woodcuts are generally sufficient, and some of the diagrams are remarkably ingenious and useful. Some are, however, much too small, *e.g.* the diagram of the skull, Fig. 197, and all the figures of entire skeletons, as 200; while others, as 137, representing the shoulder-girdle of *Hemidactylus*, after Parker, greatly need the shading and tinting of the original drawing. The plan of repeating an illustration whenever it is referred to is not often adopted in English books, but on the whole it is, we think, the most convenient.

Experience will show what class of students will really make most use of Mr. Mivart's Lessons. We heartily recommend them to all medical students and zoologists who have access to a good museum. P. S.

OUR BOOK SHELF

Die Robbe und die Otter (Phoca vitulina *et* Lutra vulgaris) *in Ihrem Knochen-und Muskel-skelet.* Eine anatomisch-zoologicgische Studie von Dr. J. C. G. Lucae. 102 pp. 15 plates. (Frankfort-on-the-Main, 1873.)

UNDER this title the distinguished anatomist, Prof. Lucae, has contributed to the "Transactions of the Senckenbergian Society of Naturalists," an elaborate treatise upon the anatomy of the Common Seal (*Phoca vitulina*). The osteology of *Phoca* is minutely described, and every part of its skeleton compared with the corresponding portions of that of the Otter—one of its nearest allies among the terrestrial Carnivora. Comparisons with other mammals are also given.

Fifteen well-executed plates illustrate this excellent memoir, which, when completed (the first part being only now before us) will leave little to be added to our information as to the osteology of the true Seals (*Phocidæ*.) To our knowledge of the structure of the two other families of the marine Carnivora (the Trichecidæ and Otariidæ) we have lately received a valuable contribution in the shape of Dr. Murie's Memoirs on the Walrus and Sea-lion, published in the Zoological Society's "Transactions," so that great progress has lately been made towards a perfect understanding of the osseous structure of the marine Carnivora.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Agassiz and Forbes

MR. GEORGE FORBES has, in NATURE of May 22, given his version of the controversy between Agassiz and Forbes. I had no intention, in a former note, of reviving, for the benefit of the readers of NATURE, this unpleasant subject; but simply wished to protest against the *ex cathedra* statements of the reviewer of Tyndall. The materials for an impartial discussion of the history of glacier work are accessible to all investigators, and when it comes to be written, Agassiz and Forbes will obtain due credit for their share of the work. One of the points at issue between Forbes and Agassiz is not a matter "of facts to be proved or disproved by facts." The conversation between Agassiz and Forbes (Heath as witness for Forbes) held on the first day of their sojourn on the Aar Glacier, refers simply to *a difference of opinion on the explanation of certain bands* (observed previously by several persons, and well known to Agassiz). The nature of these bands has to this day remained problematical and why Agassiz, when writing to Humboldt that *he had observed these bands at a depth of* 120 *ft. in the body of the glacier*, should give any credit to Forbes passes all understanding. This observation was made after Forbes's departure, and Agassiz certainly needed no "reconciliation with his conscience" to describe this as "le fait le plus nouveau que *j'ai* observé." The testimony of Mr. Heath is of no value, for it certainly would be the height of presumption, in a man without any previous acqnaintance with glaciers, to undertake to decide in a few lines, a point to this day a subject of controversy among investigators of glaciers; his endorsement of the claims of Forbes is as ridiculous as the attempt made by a prominent Swiss geologist (who gives his testimony in favour of Forbes), to ignore the claims of Agassiz, by passing his name over in silence when writing the history of geological science in Switzerland.

I would also remind Mr. George Forbes and the editors of the "Life and Letters of Forbes," that Agassiz's affirmation carries as great weight as that of Forbes or Mr. Heath. Forbes is entitled to whatever credit there is in his explanation of these bands and no more, an explanation which has not been adopted by Agassiz for the very good reason that he did not deem it a satisfactory one, and did not attach to it the same importance which Forbes did. Agassiz expressed to Forbes considerable surprise at the appearance of the bands which presented that morning peculiar conditions, not usually seen except after a hard rain, and on the strength of this surprise Forbes lays claim to the discovery of the bands, and boldly accuses Agassiz of knowing nothing about them at the time of his visit. In investigations carried on for several years, as those of the glacier of the Aar under Agassiz, it was most natural that special points should not always be uppermost in the mind of the investigator, however interesting they might appear to a visitor; this will fully account for any want of interest shown by Agassiz on first meeting Forbes and discussing the veined structure of the ice.

Agassiz certainly owed nothing to Forbes, who was an invited guest on the glacier of the Aar, a novice in glacial work. No attack was made upon Forbes, as is stated by Mr. George Forbes; it originated with him. In a letter addressed to Forbes by Agassiz when he first discovered that Forbes had published, independently as his own, observations made upon the glacier of the Aar, during his stay with the Swiss party, he says: "the idea that in thought you conceived the project of an independent publication did not come to me for an instant. I should have thought I did you injustice by such a supposition." Agassiz felt *he* "had been deeply wronged" by the course taken by Forbes; he made no answer to Forbes, and paid no further attention to the subject, not because there was "no room for discussion," but because the tone adopted by Forbes was so insulting and overbearing as to render all further discussion impossible without its degenerating into the personalities afterwards indulged in by Forbes, in his letters to his friends, which the editors of his Life and Letters have taken special pleasure in reproducing.

Forbes did not hesitate to bring Mr. Heath uninvited to the glacier of the Aar, probably to act as his witness and swel the party, yet both he and his son regard the presence o friends of Agassiz, to assist him in his work, a most monstrous circumstance. Pioneers usually find it difficult to explore the

way, but when the track is once blazed it is easy enough to follow and find the path.

As I do not wish to fill the pages of this journal with personal explanations, my contributions in NATURE to this subject must cease with this note. It is not my purpose at present to refute the imputations cast upon Agassiz by the editors of Forbes's Life and Letters; he can well afford to pass them over as he has done thus far, in silent contempt, the more so since, fortunately for Agassiz, the editors have given us from Forbes's own letters all that was necessary to show a course of duplicity, on Forbes's part, towards the man with whom "he served his apprenticeship in glacier observation," which is happily rare among scientific men.

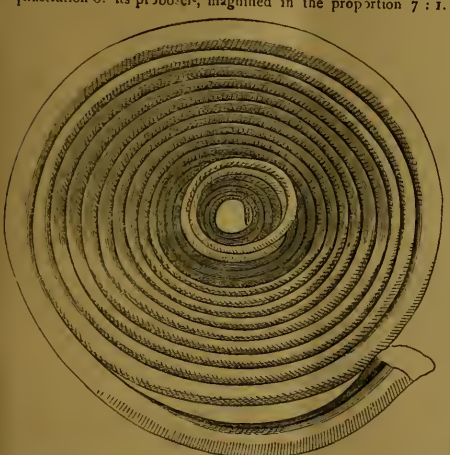
ALEXANDER AGASSIZ

Probosces capable of sucking the Nectar of Angræcum sesquipedale

MR. W. A. FORBES, in the number for June 12 started the question, whether moths are known to inhabit Madagascar with probosces capable of such an expansion, as to obtain the last drops of the nectar secreted in the lower part of the whip-like nectaries of *Angræcum sesquipedale*.

As long as a direct answer to this question has not been given, it may be of some interest to state in general the existence of moths provided with probosces sufficiently long for the honey-spurs in question.

Some days ago I received a letter from my brother, Fritz Müller (Itajahy, Prov. St. Catharina, Brazil), in which be says: "I recently caught a Sphinx (not determinable by Burmeister's "Brazilian Sphingidæ"), the proboscis of which has a length of about 0·25 metres—a length not approached by any honey-tube of this country known to me. I enclose the proboscis." Being unable to get the name of this species of Sphinx, I append the illustration of its proboscis, magnified in the proportion 7 : 1.



This proboscis, in its contorted condition forming a roll of 10-11 millimetres in diameter, and showing at least 20 elegant windings, in its expanded condition attains a length of between 10 and 11 inches, and would consequently be adapted to the nectaries of *Angræcum sesquipedale*, which have been found by Darwin $11\frac{1}{2}$ inches long, with only the lower inch and a half filled with nectar. Darwin indeed says, with regard to the fertilisation of *Angræcum sesquipedale* (p. 198 of his work on Orchids): "there must be moths with probosces capable of extension to a length of between 10 and 11 inches."

HERMANN MÜLLER

An Order of Merit

YOUR leading article in the last number of NATURE on the subject of a proposed "Order of Merit for Scientific Men," recalls the views (in exact correspondence with your own) entertained by my brother-in-law, the late J. Beete Jukes. These were expressed by him in no uncertain terms on the occasion of publishing an address on the Geological Survey, delivered in Dublin in 1865.

I take the liberty of sending you a print for your perusal, and to refer to note B, at p. 21. I was glad to see the subject so well dealt with in your article.

ALF. H. BROWNE

5, West Hill, Highgate

"Men of science have of late years pandered too much to the utilitarian quackery of the age, and it is time that some one should stand up to protest against it. Government and the House of Commons should be told that Science must be supported and encouraged for her own purely abstract purposes, independently of all utilitarian applications. The necessary preliminary, indeed, to these utilitarian applications is the discovery and establishment of abstract scientific truth by men who look to that alone, and whose whole faculties and lives are devoted to it. The men who afterwards make the practical applications of it often attain, indeed, far wider reputations than the real men of science, and become to the popular gaze the representatives of Science itself. The higher class are rarely much known to the public during their lives, and are not usually men who would experience any satisfaction if they were nick-named Knights or labelled with C.B., or would feel inclined to accept any other crumbs that might fall from the table of the politically great and powerful. Nor would they commonly care much for pecuniary rewards, unless as a means to enable them to do their work without drudging for the support of themselves or their families. They are the men, however, who in the end rule the world, and doubtless they are often sustained in their labours by a consciousness of this fact.

"It would manifestly conduce to the public good and the national honour if such men, when they do arise amongst us, should be sought out, recognised as public benefactors, and allowed means to do that work which their faculties, and theirs only, enable them to perform" ("Her Majesty's Geological Survey of the United Kingdom," &c., by J. Beete Jukes, F.R.S. 1867.)

Geological Subsidence and Upheaval

SIR J. HERSCHEL thought that the earth's crust floats upon an ocean of molten matter, and that the washing of detritus from the land into the sea, by altering the relative weight of different portions of the shell, occasions a subsidence of the ocean's bed and an upheaval of the land, which may be either gradual and insensible, like the process of denudation, or spasmodic and by fits and starts producing earthquakes and sometimes volcanic eruptions.

This theory was at one time adopted, at least partially, by Sir C. Lyell, but is not mentioned in the latest edition of his "Principles," and is generally rejected by geologists as at variance with the opinion held by Sir W. Thomson and others in regard to the internal solidity of the earth. But this objection may be avoided by modifying Sir J. Herschel's theory. We may repudiate his hypothesis that a great fiery ocean exists below the outer crust. We may arrive at many of the important conclusions which he drew from this hypothesis, and which he described as all that a geologist could require, by admitting either that *solid rocks are plastic*, or that *some of the lower and warmer strata of the earth are more pliable than the upper*.

As to the plasticity of solid bodies, it may be sufficient to refer to the experiments of M. Tresca (Comp. Rend. de l'Acad., 1864–65, and Annales du Conservatoire, No. 21). Dr. Tyndall (Glaciers of the Alps, p. 9) suggests the possibility that the contortions of the strata in the valley of Lauterbrunnen may have been produced by pressure acting throughout long ages on the rocks in their present hard and solid condition.

Again, the lower strata of our globe may be rendered more pliable than the superincumbent rocks by the great internal heat, although it may be insufficient to fuse them or even to maintain them in a viscous condition. Many of the geological effects of a molten ocean may thus be produced.

The theory that volcanic eruptions are caused by water percolating through superficial cracks may, perhaps, give a clue to the reason why volcanoes often occur in a great circle round the globe and in diametrically antipodal positions. When other causes concur to modify the form of the earth, the tidal strain occasioned by the sun and moon may often be required to overcome the *vis inertiæ*; this strain being greatest in the great circles of the globe perpendicular to the direction in which the sun and moon happen to be, cracks would probably occur most readily in these circles.

It seems at least a curious coincidence that some areas of recent

subsidence, *e.g.* coral reefs and islands, are parts of the earth's surface which have lately increased rapidly in weight; and it may be worthy of consideration whether coral and volcanic islands have contributed to deepen the bed of the ocean.

Cauterets, Hautes Pyrenees, July 12

Curious Rainbow

AN unusual atmospherical effect was witnessed here to-day, which I had a good opportunity of observing. The sun was about 8° from the horizon, shining brightly upon a heavy shower which had a background of dark clouds. The result was, of course, a double rainbow of remarkable brilliancy. In addition, however, to the ordinary circular and concentric bows, there was a third of an elliptical form, the two ends of which respectively sprang from the two ends of the inner arc, while the elliptical curve cut the outer arc at each extremity of a chord, which was parallel to, and which intersected the normal radius at a point about two-thirds of its length above, the diameter that formed the common base. The top of the elliptical bow was thus the outermost of the three, but the space between its inner margin and the outer margin of the second bow, although quite distinct, was not large.

The appearance of the third bow was due to light reflected from the sea. The sun being low, the resulting line of reflection was long, and it was the linear character of the source of light which gave the elliptical form to the bow it occasioned.

Dunskaith, Ross-shire, July 10 GEORGE J. ROMANES

CHLOROPHYLL COLOURING-MATTERS *

II.

I THINK there can be no doubt that the spectra of the various yellow substances given in Pl. II., Figs. 3, 4, and 6 of Dr. Kraus's work, are due to a variable mixture of xanthophyll, yellow xanthophyll, and lichnoxanthine. These can be separated, and do occur in different kinds of plants, either alone or mixed in such variable proportions that the spectra of the solutions show the absorption-bands, not only in variable positions, but also much less distinctly in some cases than in others. This difference is ascribed by the author, not to a variation in the relative proportion of two or more substances, each having definite and unvarying characters, but to the modification of one single substance, due to some unknown cause, assigning as a reason for this supposition that the chemical reactions are the same, and that the positions of the absorption-bands vary so gradually from one extreme to the other that no distinct demarcation can be detected. Now this is so very fundamental a question in such studies, and, according as it is decided, would modify the conclusions so much, that it is requisite to discuss it somewhat fully. No doubt the position of the absorption-bands seen in the spectra of solutions in different liquids does differ very considerably, but I feel persuaded that the spectrum of the same chemical compound, dissolved in the same liquid, is the same in all cases; and that, if there is any difference between the spectra of two similar solutions, it is due to a difference in the substances themselves. I would restrict the term *modification* to those changes sometimes produced by the action of weak alkalis or acids, or by deoxidizing reagents, which are only of a temporary nature, so that when the solution is restored to its original state, the spectrum is seen to be just as at first. We really do require such a term, and I have myself constantly used it in this sense. There is, however, no such relation between the different colouring-matters belonging to what I have called the xanthophyll group; and, though the presence or absence of oily substances may, and sometimes does, materially influence the position of the absorption-bands seen in the spectra of plants themselves, yet, when dissolved in a relatively large quantity of a solvent, this effect is altogether overcome. As I have shown in my late paper the position of the absorption-bands in the different members of the xanthophyll group is very different, and yet it would be easy so to mix them as to have a perfect series of connecting links, and in my opinion the variations from what appear to be independent compounds may be explained in an extremely simple and satisfactory manner, without supposing that the optical characters are subject to any such variations as are ascribed to them by the author. Whenever I have met with these variations I have looked upon them as presumptive evidence of there being a mixture, and have always been able to prove the truth of this principle by subsequent conclusive experiments. The following example will serve very well to explain my views. Many yellow flowers are coloured by a variable mixture of what I have called xanthophyll, yellow xanthophyll, and lichnoxanthine. The former occurs separately in the Alga, *Porphyra vulgaris*, the second in such pale yellow flowers as the yellow *Chrysanthemum*, and the last in the yellow fungus, *Clavaria fusiformis*. The absorption-bands of these two kinds of xanthophyll are in a very different position, and the lichnoxanthine gives no bands, only an uniform absorption, extending over about one half of the spectrum from the blue end. The chemical reactions are also equally distinct. On dissolving each in absolute alcohol, and adding a little hydrochloric acid, the first fades slowly, without being first changed into another yellow substance, and without turning blue or green; the second is first altered into another yellow substance, giving a spectrum with two absorption-bands in a different position, and then turns to a deep blue, whilst the last remains unchanged for a much longer time, and fades very slowly. Now, of course, if all these were mixed together in variable quantities, we should get results varying according to the relative amount of each. The absorption-bands due to the two kinds of xanthophyll would lie in an intermediate position, according to the relative amount of each constituent, and would be more or less indistinct, according as there was more or less of the lichnoxanthine; and on adding a little hydrochloric acid to the solution in alcohol the colour would turn to a more or less blue green, and subsequently fade to a pale or deeper yellow, according to the relative quantity of each constituent.

In order to make my meaning more clear, let us suppose that we were to take a mixture of equal quantities of xanthophyll and yellow xanthophyll. Using the notation I have so often explained in former papers, the centres of the absorption-bands of the spectra of a solution in bisulphide of carbon would then be—

Xanthophyll	$6\frac{1}{2}$	8
The above mixture	$6\frac{3}{4}$	$8\frac{1}{4}$
Yellow xanthophyll	7	$8\frac{1}{2}$

Now on exposing solutions of xanthophyll or yellow xanthophyll to the sun both fade, and if examined when very little colour was left undecomposed, the bands would be seen to be in the same position as at first, the solution being in fact just as if a large part of the colour had been removed, or as if it had been much diluted. In the case of the mixture this would not be the case. Xanthophyll is more rapidly decomposed than yellow xanthophyll, so that when very little colour was left the bands would be no longer in the original position, but in the same place as those of yellow xanthophyll, showing that a small quantity of this is left, when all the other has been destroyed. If some lichnoxanthine had been mixed with the solution, after longer exposure to the sun no absorption-bands would be seen, only the general absorption due to that substance. Moreover if we took equally deep coloured solutions in absolute alcohol of the same three different specimens, and added a little hydrochloric acid to each, the xanthophyll would fade till it was colourless, the yellow xanthophyll would turn to a fine blue,

* Continued from p. 204.

and the mixture would also turn blue, but of only about half the depth of colour. If lichnoxanthine had been present it would have caused the colour to be green; and, after the blue product had faded, it would remain as a residual yellow. By experimenting with such known mixtures we therefore see that, independently of being able to partially separate the constituents, the evidence of the solution being a mixture consists in the difference in the position of the absorption-bands, in the change in their position, or disappearance, when partially decomposed by light, and in the relative quantity of blue substance formed by the action of hydrochloric acid, and of the residual yellow. Such, then, being the case, we know what kind of methods to employ in studying natural coloured solutions, suspected to be mixtures; and on applying them to the investigation of the solutions obtained from leaves and flowers, I find that they behave exactly like such artificial mixtures, and not only so, but there is generally no difficulty in more or less perfectly separating the constituents, so as to correspond more or less closely with the different substances in their more pure state. The evidence of their being mixtures is therefore as good as could be expected. Kraus seems never to have made such experiments, and yet he strongly criticises what I had said about the existence of several distinct kinds of xanthophyll; but I contend that by adopting the principles I have described, we can completely explain the various facts on perfectly simple principles, without supposing that the optical characters of any single substance are subject to variations from some unknown, and, as I believe, altogether imaginary cause.

The flowers of different varieties of *Eschscholtzia californica* are also a good illustration of my views. The very yellow petals are coloured by yellow xanthophyll, with a very little xanthophyll and lichnoxanthine, and thus correspond with many other similar flowers, but the more orange-coloured petals, and the orange-coloured portions of the yellower petals, contain in addition, another colouring-matter, giving the absorption-band in the green shown in Plate II. Fig. 7, at 1 *a*, of Kraus's work which, however, he did not look upon as evidence of a mixture—merely of what he calls a modification. Now, on exposing such a solution in bisulphide of carbon to the sun, this orange-coloured substance is more rapidly decomposed than the others, and in a while a yellower solution is left, which gives exactly the same spectrum as that due to the colouring-matter from the yellow petals. According to this view of the subject we therefore see that the yellow flowers are of the usual type, and that the more orange-coloured portions of the petals, and the whole of the orange-coloured varieties differ only in there being developed an unusual and independent substance, which in this case is of orange-colour, whereas in the flowers of some other plants, such additional colouring-matters are red or blue, as the case may be, and instead of being allied to xanthophyll, differ in almost every particular.

In conclusion I would say that the yellow colouring-matters, soluble in bisulphide of carbon, which exist in green leaves, are the above-named xanthophyll, yellow xanthophyll, and lichnoxanthine. This is probably the reason why this is also the normal type of yellow flowers, and why only in particular cases one or both of these substances are absent. To this I attribute the statement of the author that the chemical reactions are the same, for he has apparently never examined those plants which yield them in an approximately pure state.

In Pl. III. Fig. 2, Kraus gives a representation of the spectrum of a coloured solution obtained from certain species of *Oscillatoriæ*. This he has named *phycoxanthine*; but I am persuaded that the solution must have contained three perfectly distinct colouring-matters, which can be separated by chemical and photo-chemical methods, and do occur almost, or quite, separately in other plants. For one of these substances I have adopted the author's name phycoxanthine. It may be obtained in the most pure state from the lichen *Peltigera canina*, when growing in such a damp and shady situation, that very little orange lichnoxanthine is developed. When dissolved in absolute alcohol and hydrochloric acid is added, it fades without turning blue. Another constituent of the mixture is what I have called *fucoxanthine*, which occurs quite free from phycoxanthine in *Fucus* and other olive *Algæ*, and even in the same species of *Oscillatoriæ*, growing where there is very little light, as those which contain phycoxanthine, if growing well exposed to the sun. When dissolved in absolute alcohol and hydrochloric acid is added, it turns to a splendid blue. The third constituent of the mixed solution is what I have named *orange lichnoxanthine*, which can be obtained by itself from lichens, and is left when such a mixed solution as described by the author, in bisulphide of carbon, is exposed to the sun under green glass, until the phycoxanthine and fucoxanthine have been destroyed. When dissolved in absolute alcohol and treated with hydrochloric acid it fades very slowly. The relative amount of this is greatest in those specimens of *Oscillatoriæ* which grow very much exposed to the sun and air, and I have found by careful comparative quantitative analyses that the relative quantity of these various substances, which together constituted the author's phycoxanthine, varies in such a manner that, as far as the fundamental colouring-matters are concerned, the same or closely allied species of *Oscillatoriæ*, growing exposed to a varying amount of light, furnish a most interesting series of connecting links between olive *Algæ* and lichens. When their vitality and constructive energy are very much reduced by want of light, their type of colouring closely approaches to that of olive *Algæ*, whereas when they are exposed to much air and light, the type approaches to that of such lichens as *Peltigera canina*. I have met with other analogous cases, and if more extended research should still further confirm the existence of this analogy between the results due to abnormally reduced or increased vitality in the same kind of plants, and the normal characters of lower and higher classes of plants, it would certainly be remarkable, as showing that the vegetative energy of the lower classes is in some way or other of a lower type than that of the higher classes, and would present a striking analogy to the relation between the structure of animals whose development has been arrested, and that of those of lower organisation.

The fact of being able to prove that a coloured solution obtained from a plant is really a mixture of a number of different substances, may at first sight appear to be of very little consequence, but I trust that some of the conclusions deduced from this method of study will justify me in looking upon it as very well worthy of attention. When we come to study the various classes of plants growing under various conditions, with the view of constructing such a general science as that I have named comparative vegetable chromatology, these details become not only of the very greatest importance, but absolutely essential. By making qualitative and comparative quantitative analyses of the colouring-matters, carefully distinguishing the fundamental from the accidental, there seems every reason to believe that the petals and the foliage of plants can be brought into morphological agreement, and many of the leading classes of plants distinguished, and at the same time connected together, so as to form a continuous series, advancing from the lowest classes of animals to the highest classes of plants; whereas, if we were to look upon mixtures as independent colouring-matters, and were not to distinguish well-marked species, the whole vegetable kingdom would appear broken up and disjointed, without any chromatological continuity.

H. C. SORBY

THE NEW LABORATORIES OF THE NATURAL HISTORY MUSEUM, PARIS *

IN order to provide every facility for the higher scientific education, and induce young men to devote themselves to scientific research, the French Government have established a school of advanced study, in the form of a suite of laboratories in which young men receive a practical education *par excellence*; they are trained there in manipulations and dissections, and initiated in all those delicacies of touch, those turns of the wrist, which are traditional in the green-rooms (*coulisses*) of science, but which cannot be taught in the theatre.

Without noticing at present the zoological laboratories under the zealous management of M. A. Milne-Edwards, and through which have already passed several students desirous of taking the degree of licentiate in natural science; or the physiological laboratory, at the head of which is the eminent M. Claude Bernard, or the laboratories of comparative anatomy and geology, we shall take the reader through the Rue de Buffon, into the new buildings which contain the chemical laboratory of M. Fremy, the botanical laboratory of M. Brongniart, and the laboratory of vegetable physiology and anatomy of M. Decaisne.

M. Fremy had already, for many years, assembled his pupils in the old Museum buildings, badly lighted, small, confined, where they were very uncomfortable; now, on the contrary, they are installed in a new building where they are furnished with every convenience for their work.

As soon as we enter the court, we find on the right and left, platforms (*paillasses*) in the open air with a glass roof, where all experiments can be made, of a nature to taint the atmosphere of the laboratories. On each side are ranged buildings, one specially intended for beginners, the other for more advanced students. The latter is provided with furnaces, by means of which the

Laboratory of Vegetable Physiology in the Paris Museum of Natural History

highest temperatures may be obtained. Each pupil has his place marked out, his name inscribed upon the frame above his work-table, which is furnished with a set of drawers and a rack for holding the *matériel* appropriate for his special work. The laboratory of the assistant naturalist, M. Terreil, and the preparatory laboratory, are situated in a line with the pupils' laboratory.

The bottom of the court opens into a lobby which communicates with the two wings of the building; here are conveniences for depositing the clothes which the students exchange for their working garb on entering the laboratory. A door in this corridor gives access to an antechamber into which open the laboratories of M. Fremy, and that of his special assistant, placed side by side.

The first and second stories of the buildings on the right and in the centre are intended for the botanists of M. Brongniart, who have not yet obtained complete possession; the left wing belongs as yet to chemistry; on the first story is the lecture-hall, on the second the library.

M. Fremy has realised the foundation of a true school of chemistry; not only does he lavish on his pupils his instructions, but he sees that their education is complete. Every day at three o'clock work in the laboratory ceases, and oral instruction begins, the lecture-hall, moreover, being open to the public. M. Fremy gives instruction in general chemistry, with a well-known power of exposition; M. Terreil has charge of analysis; M. Ed. Becquerel, of the Institute, initiates the students in the management of physical apparatus; Jannetaz, assistant in mineralogy, gives instruction in that branch; and lastly, M. Stanislas Meunier, already known by his researches upon meteorites, treats of all the parts of geology which are connected with chemistry. Examinations are held by the lecturers for the purpose of testing the work of the pupils, who are rewarded at

* From an article in *La Nature*, No. 1.

the close of their studies with certificates testifying to their diligence and their acquirements.

All this instruction is absolutely gratuitous. M. Fremy wishes to remain faithful to the old motto of the museum, "Tout est gratuit dans l'établissement," though this excessive liberality is perhaps open to criticism.

Behind the magnificent chemical rooms we found the modest laboratory of M. Decaisne. Descending a few steps we reach a garden set apart to experiments in culture, having on the left a glazed gallery: this is the laboratory of vegetable anatomy and physiology. M. Decaisne superintends and advises the anatomists during his daily visits; M. Dehérain, who is well known for his researches in agricultural chemistry and vegetable physiology, directs the work of the laboratory represented in our illustration. It is a long apartment, perfectly lighted, into which stream the rays of the sun, that plays so important a part in all the phenomena of vegetable life; on the right, ventilators carry off all the strong-smelling gases which the chemist is obliged to employ; long tables, furnished with earthenware vessels, extend along the middle of the apartments as well as underneath the windows. Everything is scrupulously tidy.

This laboratory of agricultural chemistry will no doubt yield to agricultural chemistry important results. The man of science will have here the means of preparing at pleasure true artificial soils; he will see plants of various kinds grow under his eyes; he will nourish them with organic and mineral substances whose composition is known to him. He will follow step by step the various phases of vegetable life; he will study the yet mysterious laws of vegetable life. Indeed it is difficult to state all the powerful resources that are in the hands of the experimenter.

AËRIAL SPECTRES

IN an article on the above subject in *La Nature*, No. 4, M. G. Tissandier gives the following account of what he saw from a balloon on February 16, last.

At mid-day we quitted the earth wrapped in a thick mantle of fog; after traversing the mass of the clouds, we were suddenly dazzled by torrents of light which shot

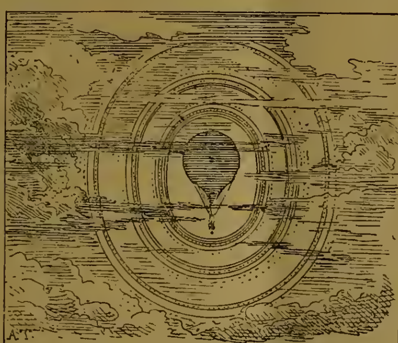

FIG. 1.—Shadow of a balloon surrounded by three aureoles.

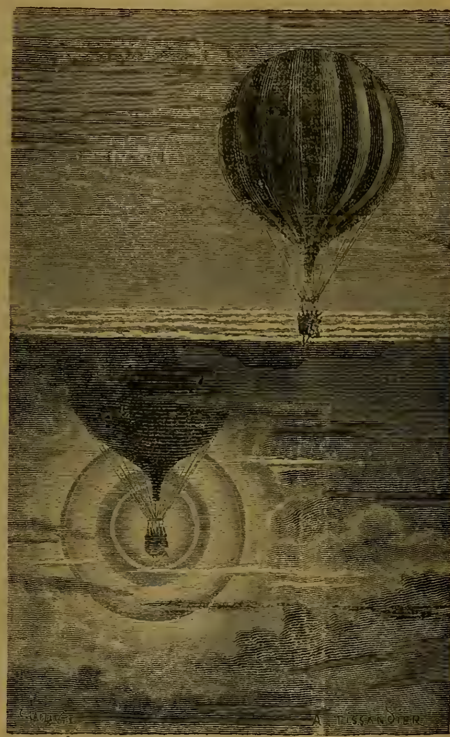
from a tropical sun, a stream of fire, in the midst of an azure sky. Neither the *mer de glace* nor the snowy fields of the Alps, give an idea of the plateau of mist which stretched under the car like a glassy circle, in which valleys of silver appeared in the midst of flakes of gold. Neither the sea at sunset nor the ocean waves when lighted up by the orb of day at noon, approach in splendour this array of circular cumulus, but which have, in addition, "the light that never was on sea or land."

When our balloon had passed about 50 metres beyond the plain of clouds, its shadow was projected with remarkable precision, and a magnificent circular rainbow appeared round the shadow of the car. Fig. 2 gives a very exact idea of the phenomenon. The shadow of the car formed the centre of rainbow-coloured concentric circles, in which were distinctly seen the seven colours of the spectrum, violet, indigo, blue, green, yellow, orange, and red. The violet was inside, and the red on the outside, these two colours being at the same time those which were seen with the greatest distinctness. We were,



G. 2.—Optical phenomenon observed from a balloon.

at the time the observation was made, at a height of 1,350 metres above the level of the sea.

The balloon, the gas in which expanded under the heat of the sun, continued to rise rapidly in the air, its shadow visibly diminishing; soon, at a height of 1,700 metres, the rainbow-circle enveloped it entirely, and disappeared from around the car. A little later, at about $1^h\,35^m$, we approached the bed of clouds, and the shadow was girt this time by three silver-coloured aurioles, elliptical and concentric, as shown in Fig. 1.

Nothing can give an idea of the purity of these shadows, which are cut out in an opaline mist, or of the delicacy of tone of the rainbow which surrounds them. The complete silence which reigns in the aërial regions, where this play of light is seen, the absolute calm which

exists there, above clouds transformed by the sun into flakes of light, adds to the beauty of the spectacle, and fills the soul with inexpressible admiration.

We do not yet know exactly to what cause to attribute the production of a luminous contour around the shadow projected upon vapours or mists. Some observers have thought that these phenomena are due to the diffraction of light, but it is possible that they have a common origin with the rainbow. What tends to confirm this opinion is the necessity for the presence of the vapour of water as a necessary condition of the phenomenon: if it is the result of diffraction, it ought to appear as well upon a white wall, or any kind of screen, as upon a cloud. It is possible, moreover, to study these curious phenomena by means of experiments upon the earth; by suitably arranging screens of silk or muslin saturated with water, which resemble a cloud, we may expect to be able to produce the phenomenon. M. Leterne points out another excellent method of studying it. On a spring morning, when the sun, about 15 or 20 degrees above the horizon, has warmed the atmosphere a little, and has produced a light condensation of vapour upon the grassy borders of the roads, one may see his silhouette projected upon the humid verdure, surrounded by a luminous contour, in which is seen the colours of the spectrum, the red, however, being strongest.*

THE GEOLOGICAL SURVEY OF INDIANA

GEOLOGY is a branch of Science which specially commends itself to the fostering care of Governments, paternal or otherwise. More particularly is this true of a new country, where, in the imagination of the settlers, untold wealth has yet to be dug out of the earth, if only they could discover in what quarter best to look for it. Accordingly, in not a few of our colonies and in a number of the States of the Union, geological and mineralogical surveys have long been at work, originated and continued at the public expense. In most cases, of course, the first aim of such surveys, and in fact the very justification of their existence in the eyes of practical and by no means scientific legislators, is the finding of mineral wealth. If they were begun from the lofty scientific point of view they would fail, and deservedly. But when a really able scientific man gets the charge of one of them, and has at the same time that mother-wit and knowledge of the world which scientific men so often lack, he may not only attend to the rigid economics of his paymasters, but do great service to geology. His aim is to show the public that a strictly scientific basis is the only one on which a mineral survey to be of any value can be conducted. And this is so obvious that if it is simply and clearly stated, it for the most part commends itself to the common-sense of public men. In laying this necessary basis and then in carrying out the survey for economic minerals the geologist may both pave the way for an enormous increase to his country's industry and wealth, and add much of permanent interest and importance to the common stock of geological knowledge.

Perhaps the most notable illustration of the successful accomplishment of this double mission is furnished by the career of Sir William Logan, whose practical kindly ways enabled him to triumph over the shortsightedness of colonial obstructionists, and whose patient and sagacious labours among the rocks of Canada have made his name honoured and familiar all over the world, and have conferred distinction also upon his country. In the United States, too, fostered by the liberality of the Legislatures, a number of admirable State surveys have been made, or are still in progress. Under the auspices of such men as James Hall, Owen, the Hitchcocks, the brothers Rogers, Hayden, Whitney, Blake, Cook, and others, not only have maps been constructed, but elaborate reports have been published, embracing, in addition to the paramount economics, much valuable information in geology, mineralogy, and palæontology.

* *Comptes Rendus*, t. lxxvi. p. 786.

One of the latest of these State surveys is that of Indiana, which was started some four years ago under the direction of Prof E. T. Cox. Like those already referred to, it was organised by the authorities "for the purpose of collecting information designed to promote the interests of agriculture, arts, manufactures, and mining." But it was furnished at the same time with an analytical laboratory "for analysing such ores and substances as may be deemed useful to the State," and with space "to build up a geological and natural history cabinet," while in order to render its labours as speedily serviceable as possible, an annual report of progress was required to be issued.

Prof. Cox has evidently a hard task before him. He has been invited to become a kind of depository of all the mining information in the State. He is to see that trustworthy mineral surveys are made, and at the same time he is expected to look after the laboratory and infant museum at Indianopolis and—perhaps most laborious but not least useful of all—to receive everybody who wants to know about coal, iron, or other mineral produce, and to collect and furnish to such inquirers all the information procurable. He generously says in one of his reports that this latter part of his duties "has always given him pleasure," though he confesses that it has consumed a considerable portion of his time. Fortunately he can count on the help of a small but apparently able staff of assistants, and notwithstanding all the obstacles in his way he has succeeded in getting through a large amount of work which, though not yet of high scientific value, must bear most importantly upon the future development of Indiana.

Three volumes of reports with maps have been published, bringing the account of the progress of the Survey up to the end of last year. Each of these neatly printed and not too bulky octavos describes several counties of the State with reference chiefly to the distribution of economic minerals; and the maps which accompany it, though roughly and cheaply executed, are clear and must be of infinite service to the many speculators and others who every year come in increasing numbers into the state in search of mineral investments. The coal-field of Indiana, though only a part of the larger basin of Illinois, is estimated to equal more than half of the area of the whole of the coal-fields of Great Britain and Ireland. Some of the coal-seams are of excellent quality, specially that known locally as "block-coal," which is said to be unrivalled for iron-furnaces. Abundant iron ore likewise occurs. Hence not only coal-pits but iron-works are springing up in rapidly increasing numbers. Not a little of this wonderful rapidity of growth is attributed by Prof. Cox, and no doubt justly, to the extended and more accurate knowledge of the minerals which the Survey has been able to publish. In the course of two or three years tracts of "primeval forest" have vanished, and in their place the visitor would now see clanking engines and mining villages, crowded with a population as busy and begrimed as any to be met with in Staffordshire or Lanarkshire. And yet vast though this change is, it may be said to have only just begun. Before many years are over the coal-bearing part of the formerly quiet agricultural state of Indiana will become one of the most active centres of industry in the Union, with railways diverging in all directions to carry away its mineral produce.

Prof. Cox and his assistants have not only been successful in pointing out the mineral resources of the various counties. In looking through his reports one can see that he continues from year to year to slip in more of general scientific interest. This is notably the case with the volume lately published. In addition to a series of

elaborate analyses of coals, we find that in the coal-pit sections the names of characteristic fossils have found their way into the text, that notices are given, not merely of the economically useful minerals, but of the geological formations which have no special industrial value,—Silurian, Drift, River-terraces, &c. The volume contains also meteorological tables and notices of recent geological changes. But by far the most interesting contribution to science in its pages is a "Report on the Wyandotte Cave and its Fauna," contributed by Prof. E. D. Cope, with an account of the geology of the cave, by Prof. Cox himself. This remarkable cavern runs through the "sub-carboniferous" limestone in numerous branches which are said to have a total length of twenty-two miles, and greatly to excel the more famous Mammoth cave of Kentucky in the number and beauty of their stalactites. It contains a peculiar fauna, numbering at least sixteen species, which show a general resemblance to those of the latter cave, and include one species of blind fish (*Amblyopsis spelæus*) which lives in the subterranean waters of Kentucky.

In these Reports each county is described separately, so that the same geological facts require to be frequently repeated. This is, doubtless, the most useful arrangement for those for whom the volumes are primarily intended. But it would be a service to other readers if a good table of contents were given, and if the index were made much fuller, especially in matters of general geological interest. The volumes are eminently praiseworthy, and we hope to see them followed, before long, by a good map and a general geological Report of the whole State of Indiana.

A. G.

INTELLECT OF PORPOISES

A SINGLE visit to the Brighton Aquarium would suffice to convince a recent correspondent, Mr. Mattieu Williams, that the intellect of the porpoise, as foreshadowed by its convoluted brain, exceeds, beyond comparison, that of the cod-fish or any other representatives of the piscine race. Of the two specimens now inhabiting the largest tank in the building, over one hundred feet long, the first-comer so readily accommodated itself to its altered conditions, that on the second day it took its food, smelts and sprats, from its keeper's hand, and has continued to do so ever since. The later arrival was, at first, less sociably inclined; but both have latterly become equally tame, and frequently, while receiving fish from my hand with the gentleness of pet dogs, have permitted me to pat and stroke their slippery india-rubber-like backs.

During feeding-time it is amusing to watch the avidity with which these porpoises take their food; one, the more active of the two, usually securing the lion's share, and displaying marked sagacity by frequently snatching a second or third morsel before disposing of the first.

The keeper in charge of these interesting animals is now in the habit of summoning them to their meals by the call of a whistle; his approaching footsteps, even, cause great excitement in their movements, and recent experiments have proved them to be acutely sensitive to the vibrations of sound. By the physiologist a more pleasing spectacle can scarcely be witnessed than the graceful actions of these cetacea, as they swiftly pursue their course up and down their spacious tank, ascending to the surface of the water at intervals of fifteen or twenty seconds, to breathe, each inspiration being accompanied by a spasmodic sob-like sound, produced by the rush of air as a breath is rapidly liberated and inspired through the single central blow-hole.

Onward progress is effected in these animals, as in all other cetacea, exclusively by the action of the horizontal caudal fin; the development of muscle at the "wrist" of the tail on which this action depends being enormous and plainly visible externally; the pectorals are devoted principally to the purpose of steering the creature to the right or left, aiding it also in rising to the surface of the water.

The fact alone of the porpoise suckling and evincing much maternal solicitude for the welfare of its young indicates the superiority of its position in the zoological scale above that of the other representatives of the finny tribe; and to this, in addition to the remarks just made upon their sagacity when feeding, many other facts may be cited, pointing in the same direction. The curiosity attributed to these creatures, as illustrated by the experiences of Mr. Mattieu Williams, receives ample confirmation from their habits in confinement. A new arrival is at once subjected to the most importunate attention, and, advancing from familiarity to contempt, if disapproved of, soon becomes the object of attack and persecution. A few dog-fish, *Acanthias* and *Mustelus*, three or four feet long, placed in the same tank, soon fell victims to their tyranny, the porpoises seizing them by their tails, and swimming off with and shaking them in a manner scarcely conducive to their comfort or dignified appearance, reminding the spectator of a large dog worrying a rat. The fine sturgeon, six feet long, now sharing an adjoining tank with the cod, was first placed with these animals, but in a short time was so persecuted that for safety it had to be removed; while to this day the lacerated condition of its tail bears witness to the pertinacious attention of its former comrades. Some large skate (*Raja clavata* and *maculata*), while they maintained their usual habit of lying sluggishly on the floor of the tank, escaped molestation; but no sooner did these fish display any unwonted activity than the porpoises were upon them, and, making a convenient handle of their characteristic attenuated tails, worried them incessantly. On one occasion I witnessed the two *Cetacea* acting evidently in concert against one of these unwieldy fish, the latter swimming close to the top of the water, and seeking momentary respite from its relentless enemies, by lifting its unfortunate caudal appendage high above its surface. It need scarcely be remarked that the skate were removed before further mischief could be done, leaving the porpoises, with the exception of a few conger, which during the day-time mostly lie hidden in the crevices of the rock-work, turtles, and a huge monk-fish (*Rhina squatina*) sole occupants of this colossal tank.

While far behind the porpoises in display of intellect, it may be hereafter shown that the representatives of the *Gadidæ*, or cod-family, are by no means the least intelligent of fish.

W. SAVILLE KENT

AN INTERNATIONAL COINAGE

A PROPOSITION has been made for holding a private conference for an International Coinage at Vienna in the course of next September, and to consider more particularly the following points:—

1. The question of Valuation.
2. The principal Coins.
3. The Unit of Value, and its Sub-divisions.
4. The charge for Coining, the rate of alloy, and other technical questions.
5. The preservation of the full value of the principal Coins in circulation, and the coining of others.
6. The different modes of introducing a new money-system.

The prime mover and most active agent in the promotion of this conference is Mr. A. Eggers, Consul in Bremen. The declared object is to bring together a limited number of semi-official or private representatives of the various countries, with a view of a full discussion of the subject; and a committee has been constituted consisting of several French and German gentlemen who are interested in the question of the International Coinage.

Mr. Eggers has recently paid a visit to this country with a view of inducing some of the English advocates of an International Coinage to take part in the proposed conference. It was suggested by Mr. J. B. Smith, M.P., that a private meeting should be held to enable Mr. Eggers to explain his views, and this meeting was accordingly held on the 25th ult. at the Standards Office, 7, Old Palace Yard. But few persons, however, attended; amongst them were Dr. Leone Levi and Mr. Hendricks; Mr. J. B. Smith was himself absent from illness.

The principal propositions of Mr. Eggers, which seem to be fully explained in his printed pamphlet, entitled "Die Geldreform," published at Berlin, were—

1. That the International Coins should be of a round metric weight.
2. As common units of value, a dollar of fine gold $1\frac{1}{2}$ gramme, and a coin of 25 grammes of silver $\frac{9}{10}$ fine.
3. As nearly corresponding with the pound sterling, a coin of 5 dollars, or a new sovereign of $7\frac{1}{2}$ grammes of fine gold.

And he suggested that such a gold dollar and sovereign might be first introduced in Canada, as very nearly agreeing in value with the American gold coinage.

The objections raised against these propositions were, first, that if the fine gold in the dollar weighed $1\frac{1}{2}$ grammes, the addition of $\frac{1}{9}$ alloy would make the actual weight of the dollar $1\frac{2}{3}$ grammes, which is not a round metric weight. There would be the same result with the new sovereign of $7\frac{1}{2}$ grammes fine gold, as $\frac{1}{9}$ alloy would make the actual weight $8\frac{1}{3}$ grammes.

A far more serious objection was that the difference between the $7\frac{1}{2}$ gramme fine gold in the proposed new sovereign, and 7·32238 grammes in the existing sovereign, equal to 0·17762 grammes, would increase the value of the sovereign more than $5\frac{1}{2}d.$, which was quite inadmissible.

The question of a silver International Coin was not discussed, the general opinion being that the difficulties of agreeing upon a single gold unit were already sufficiently great, and that until they could be overcome, it was almost hopeless to expect that any International Coinage could be established. The adoption in the German Empire of the 20-mark piece as the gold coin unit, and containing 5·04*d.* less in value of fine gold than the sovereign, together with the very large amount of the new German gold coinage, appears to offer at the present time an insuperable obstacle to the common adoption of an International Coinage, however desirable it may be.

NOTES

At the meeting of the Paris Academy of Sciences on the 7th instant, three elections to the Section of Anatomy and Zoology took place. The places to be filled were those of Mr. Agassiz, elected a Foreign Associate, and MM. Pictet and Pouchet, deceased. In the first case M. Steenstrup obtained 38 votes and Mr. Darwin 6; in the second Mr. Dana obtained 35 and Mr. Darwin 12; in the third Dr. Carpenter obtained 35, Mr. Darwin 12, and Mr. Huxley 1 vote. Messrs. Steenstrup, Dana, and Carpenter were therefore declared duly elected.

The Professorship of Anatomy at King's College, London, rendered vacant by the death of Mr. Partridge, was refilled on Friday last by the appointment of Dr. Curnow, a former student of the College, whose medical career at the University of London has been one of the most brilliant on record. After having obtained the scholarships and gold medals in Anatomy and Materia Medica at the first M.B., he was equally successful at the second M.B., gaining the same honours in Medicine and Obstetric Medicine. At the M.D. examination Prof. Curnow also obtained the gold medal. We cannot but think that the Council of King's College have made a judicious selection, and have gracefully recognised talent in one of their most promising pupils.

The Royal College of Science for Ireland, in connection with the Science and Art Department, South Kensington, has conferred the diploma of associate on the following gentlemen:—Faculty of Engineering: G. P. Culverwell, E. P. Culverwell, R. W. Frazer, and E. Barrington. Faculty of Manufactures: Thomas Abbott. The two Royal Scholarships were awarded to John O. Hicks and James Patterson. The silver medal to F. A Caldwell.

"It never rains but it pours." Prof. Agassiz, as representing the Anderson Natural History School, of Penikese Island, has been presented by Mr. C. W. Galloupe, of Swampscott, with a handsome yacht of 80 tons, estimated to cost 20,000 dollars. The vessel will be used for dredging, temperature soundings, &c., along the coast in the neighbourhood of the island; its presentation makes perfectly complete the apparatus for practically training the students of the finest natural history school in the world.

The British Government has appointed Mr. Robert Scott and Mr. Alexander Buchan to represent this country at the forthcoming Meteorological Congress at Vienna. Other societies and departments which have been invited to nominate delegates will probably refuse to do so, Government having characteristically refused to pay the necessary expenses.

The Report of the College of Physical Science of Newcastle-upon-Tyne, at the end of the second year of its existence, is altogether satisfactory. The classes have been augmented from four to eleven, and the number of students shows a considerable increase over the previous session; the attendance at the evening classes is also satisfactory. The number of students attending instruction in practical chemistry has been so great as to render it necessary to make arrangements for materially increasing the laboratory accommodation. The Council are very sanguine of the success of the college, though they feel the necessity of founding more professorships and obtaining more accommodation, and think that the wealthy manufacturers and merchants of Newcastle and the North of England ought to render much more assistance than they do. We hope the wealthy manufacturers of the North will see it to be their duty, as it certainly is their interest to contribute to the success of such an institution in their midst. It would certainly be a disgrace to Newcastle if its Science College should, in the midst of enormous wealth, not attain the greatest possible measure of success. There is no reason why this institution should not be made as successful as Owens College, Manchester, and we hope that ere long similar institutions will be established in all the large towns of England. It would be a pity that those who are concerned in the management of the Newcastle institution should mar its success by any antiquated restrictions as to a knowledge of ancient languages by those who have shown themselves deserving of a degree in science.

We regret to announce the death of the eminent engineer, Mr. J. R. McClean, M.P., F.R.S.

Our readers have no doubt heard of the recent miserable thefts of living Italian coral from the Crystal Palace Aquarium. It is really difficult to find words to characterise the despicable meanness of the act. Mr. Lloyd says that these things are never taken when working people are present. Meantime the public must suffer for the act of an individual, for it has been thought necessary so to secure the corals under lock and key, that they cannot be so well seen as before, when in open tanks. We can only hope that the petty thief will be discovered: happily such acts are rare in our places of public resort.

A NEW part of the quarto "Transactions of the Zoological Society," just issued, contains three papers by Prof. Owen. The last of these is of special interest, as containing the first account of a new extinct Struthious form from Australia, proposed to be called *Dromornis australis*, for the full description of which we must refer our readers to the paper in question.

THE post tertiary fauna of Australia is extremely rich in *Macropodidæ*, or Kangaroo, many of which greatly exceed any of the existing species in size. Professor Owen has lately described a large series of these in a memoir presented to the Royal Society, and has divided them into numerous genera, founded upon somewhat minute distinctions in the characters of the teeth. We have just received from Mr. Gerard Krefft, Curator of the Sydney Museum, a photograph of the teeth of a giant of the race, the four molars together measuring from before backwards as much as three inches. It is unaccompanied by any description, and pending the publication of Prof. Owen's memoir, we are unable to say whether it belongs to either of the species described therein.

THE tank containing the Spring Lobster or Sea Crayfish, *Palinurus vulgaris*, at the Brighton Aquarium, No. 26, is invested with special interest at the present moment, on account of the appearance, during the last few days, of innumerable young. Until within late years, the early condition of this, the largest of our British crustacea, was regarded as a distinct species, allied to *Squilla*, representing the Stomapodous instead of the Podopthalmous order of their class; it was thus described by Leach under the name of *Phyllosoma commune*. The celebrated Belgian naturalist, Prof. Van Beneden, was one of the first to establish the identity of these two forms, and the result of his praiseworthy investigations was simply and amply confirmed by the recent arrivals at the Brighton tanks. In this "*Phyllosoma*" phase, the ovate body is so remarkably transparent and flattened out, that even when several inches in length they can scarcely be distinguished at the surface of the sea, where they often float in countless numbers. Some very fine examples of these crustacea, illustrating this interesting stage of their development, are exhibited in the typical invertebrate series in the Royal College of Surgeons. The specimens at the Brighton Aquarium just excluded from the egg are very minute, scarcely exceeding half-an-inch in total length, and although swarming in their tank are, on account of their extreme pellucidness, only visible on the most close inspection. The "berried hen" producing this large brood of young, was added to the collection about a month ago. An adjoining tank, No. 28, is teeming in a similar manner with the young of the Common Lobster, *Homarus vulgaris*.

THE number of the "Proceedings of the Asiatic Society of Bengal," containing a report of the annual meeting, has just been received. The chief feature of this meeting was the admirable address of the president, Dr. T. Oldham, from which we are glad to see that under the auspices of this Society, a very large amount of valuable work continues to be done to the literature, archæology, ethnology, and natural history of India. For years the Indian Government ignored the acknowledged claims which this Society had upon it, in return for the Society's handing over to Government its invaluable collection. It is gratifying to be told by the president that the Government of India have acceded in full to the claims of the Society. This gives us some hope that the Government, who have, the president tells us, sanctioned the necessary expenditure for photographic observations of the forthcoming Transit of Venus, will, as the Society desires, maintain and render permanent the small establishment about to be fixed for this object on some elevated spot, for the special purpose of solar observation in connection with meteorology. The British Association at its last meeting requested the Society to urge the Indian Government to establish and maintain an observatory for this purpose in India. The direct value, both to science and to commerce, of the work of such an observatory would be incalculable; and we hope the Society will continue importunate until the Government accede to its wishes. We are moreover glad to see that a committee of the Society has been organised to supplement the work of the *Challenger* by exploring the Indian seas, an almost virgin soil; the necessary funds for the purchase of instruments have been granted, and we hope the ship, which is all that is wanting, will be forthcoming when the instruments are ready. Altogether the Society must be congratulated on the work it does amid many discouragements.

TELEGRAPHIC intelligence has been received in Berlin announcing that the English steamer conveying the German African exploring expedition to Congo has been wrecked off Sierra Leone. There was no loss of life, but all the effects and scientific instruments of those on board were lost.

SHOCKS of earthquake occurred on the morning of July 12 at Rome, Frosinone, Alatri, and several other places. No damage was done. The shocks and subterranean roaring continue in the neighbourhood of Alpago. A rather strong shock of earthquake occurred on the same day in the Valley of Lira, at Isola. The workmen left the manufactories, and several houses were damaged.

MR. J. L. HADDEN, C.E., who was blinded by watching the electric light at Constantinople, is reported as having recovered.

ON June 15, according to the official journal of the Viceroyalty of Konieh, in Asia Minor, snow fell heavily on the mountain called Bulgardagh, in the Kaza of Erkeli. In some places the snow was five feet deep.

WE have already referred to the U.S. exploring expedition to Montana, in connection with the survey for the Northern Pacific Railroad. The correspondent of the *New York Tribune*, writing from Fort Rice in the Upper Missouri, near a newly-founded town called Bismarck, gives details concerning the organisation of the expedition, which was expected to set out from Fort Rice at the end of June. There is a large military escort as a protection against the Indians, and the scientific party is well equipped. It is expected that the waggons which carry out supplies will return loaded with specimens of the natural products of the region, especially of the Yellowstone Basin, to be arranged systematically, and deposited in the National Musuem of the United States. The results of this expedition, so liberally fitted out by the American Government, are likely to be of great service to science.

THE *Times of India* contains an account of the death of a huge boa-constrictor which infested some marshy ground at the foot of the hills near Poodoocottah. The animal was regarded as sacred by the natives, who would not molest it, although only on the morning when Dr. Johnstone and Mr. Pennington, with great danger to themselves, bravely hunted it up and shot it, it had swallowed a young child. The animal is about 21 feet long, and its stuffed skin is to be deposited in the Madras Museum.

As might be expected, Mr. G. J. Symons' "British Rainfall for 1872," considering the unusual wetness of the year, is of great interest to meteorologists. The author deserves great credit for the immense trouble he has taken in putting together in a handy and useful form such a multitude of statistics, and the great care he appears to have taken to secure accuracy. The greatest rainfall in the three kingdoms during 1872 occurred at The Stye in Cumberland, 1,077 ft. above the sea-level, where it reached the extraordinary amount of 243·98 in.; the smallest amount was at Silsoe in Bedfordshire, where it was only 26·18 in., unusually small as compared with most other places. The

volume, besides rainfall statistics, contains much that is of interest to meteorologists, including some statements on the supposed connection between rainfall and sunspot frequency, that are worthy of attention.

"THE U.S. Sanitary Commission in the Valley of the Mississippi during the War of the Rebellion, 1861—1866," is the title of a very interesting volume, giving a detailed account of the organisation and working of this benevolent commission during the American civil war. It seems to have been on the whole well organised and successful in carrying out its object, thus doing much to alleviate the miseries of that unfortunate war.

MR. FREDERICK AYRTON, barrister-at-law, long resident at Cairo, who died in London recently, has bequeathed to the British Museum a splendid library of caligraphic writings in Arabic, Persian, and Turkish, collected during many years' residence in Egypt, and the market value of which probably exceeds 3,000*l.* Mr. F. Ayrton was a perfect connoisseur in the Oriental science of caligraphy, of which so little is known, artistically, in Europe; and he devoted time and money, without stint, to this his favourite study. His collection is, perhaps, unrivalled in Europe. The gift is made on condition that the trustees set apart a room in the Museum for the exhibition of these specimens of Oriental caligraphy, and that Mr. Ayrton's Arabic scribe, Asaâd Effendy, be engaged for three or four years, at a salary of 100*l.* per annum, to draw up a catalogue *raisonné* of the contents of each series.

"LES Richesses Naturelles du Globe à l'Exposition Universelle de Vienne," by M. Bernardin, is the title of a short pamphlet called forth by the Vienna Exhibition, the author's object being to show that most of the industrial materials obtained from the animal, vegetable, and mineral kingdoms within the last forty years have been lighted upon by chance, and that if competent men were to make a thorough investigation of the subject, Nature might be made to contribute to industry a vastly greater amount of material than she at present does.

WE learn from Trübner's *Literary Record* that M. Alphonse Pinart has just published a catalogue containing a description of the different collections made during his stay in what was formerly Russian America (Alaska), brought to Europe, and is now exhibiting in one of the galleries of the Museum of Natural History, Paris. The collection comprises objects of Natural History in general, Palæontology, Conchology, and especially a rich collection of objects of high ethnographical interest, as costumes, tools, arms, &c., used by the aborigines of Alaska.

WE are indebted to *Iron* for the following:—During the recent building of a bridge in Holland one of the traverses, 465 feet long, was misplaced on the supports. It was an inch out of line, and the problem was how to move it. Experiment proved that the ironwork expanded a small fraction of an inch for every degree of heat it received. It was noticed that the day and night temperature differed by about 25°, and it was thought this might be made to move the bridge. In the morning the end out of place was bolted down securely, and the other end left free. In the heat of the sun the iron expanded, and towards night the free end was bolted down, and the opposite end was loosened. The contraction then dragged the whole thing the other way. For two days this experiment was repeated, till the desired place was reached. We find no record that the heat of the sun has ever been employed in this way before.

THE following is from *Ocean Highways*:—During the last three years a naval party, commanded by Lieutenant Simpson, has been employed by the Chilian Government to explore the western side of Patagonia. In November and December 1871, Lieutenant Simpson, whose narrative has only just been published, ascended the river Aysen, which falls into the sea in latitude 45° 20′ S., opposite the Chinos Archipelago, to the south of Chiloe. He soon came to rapids and waterfalls which stopped his boats, but he pressed on through the forest in pouring rain on foot, and crossed the Cordillera at a point where it has never before been visited. The country had no inhabitants, but it is well wooded, and signs of coal were found.

No. 5 of the "Lecture Extras" of the *New York Tribune*, contains seven lectures with numerous woodcut illustrations. The principal lectures are, "Sound and Hearing," "Voice and Speech," and The Explanation of Musical Harmony," by Prof. Elsberg, of the University Medical College, New York, "Deep Placer Mining in California," by Prof. Benjamin Silliman, of Yale College, and "The Seven Senses," by Dr. R. W. Raymond, U.S. Mining Commissioner.

ADDITIONS to the Brighton Aquarium during the past week:—3 Green Turtle (*Chelonia viridis*), 4 Green Lizards (*Lacerta viridis*), 45 Mackerel (*Scomber scomber*), 3 Sea-trout (*Salmo trutta*), 4 Bass (*Labrax lupus*), 8 Black Bream (*Cantharus lineatus*), 3 Shad (*Clupea Alosa*) 1 Scad (*Trachurus trachurus*) 2 Octopus (*O. vulgaris*), 2 bunches of spawn of Squid (*Loligo vulgaris*), a brood of young Lobsters (*Homarus vulgaris*), hatched in tank No. 28.

THE additions to the Zoological Society's Gardens during the past week include a Mississippi Alligator (*Alligator mississippiensis*) from New Orleans, presented by Mr. John Hanley; four blossom-headed Parrakeets (*Palæornis cyanocephala*) and an Alexandrine Parrakeet (*P. alexandri*) from India, presented by Mr. Hugh Nevill; six Zenaida Doves (*Zenaida amabilis*) from the West Indies, presented by the Right Rev. Dr. Stirling; a Tabuan Parrakeet (*Pyrrhulopsis tabuensis*) from the Feejee Islands, and a Wagler's Conure (*Conurus wagleri*) from Venezuela, both new to the collection; an Eland (*Oreas canna*) from South Africa, purchased; two Crested Porcupines (*Hystrix cristata*) born in the Gardens.

*ON THE GERM THEORY OF PUTREFACTION AND OTHER FERMENTATIVE CHANGES.**

II.

THE author next proceeded to describe and illustrate, by diagrams enlarged from camera lucida sketches, some of the variations he had observed in organisms found in the milk glasses when introduced into other media. Another unnamed species of Oidium closely allied to that before referred to, and like it operating as a putrefactive ferment upon urine, was seen to present strange varieties according to the fluid in which it grew and the length of time it remained in it; yet, when placed in boiled milk, it returned to exactly the same character which it had when in the flask of unboiled milk in which it was first observed. But still more remarkable modifications were seen among the Bacteria. One species of very large size, but of ordinary form and movements, as seen first in the milk, presented the following, among other varieties. In Pasteur's solution it grew as motionless algoid threads with nucleated segments. In urine and turnip infusion it did not grow at all, nor did it in the albuminous fluid till boiled and cooled solution of sugar of milk had been added, when it returned to its original Bacteric form at first, but afterwards assumed the characters of a toruloid organism. In boiled milk it resumed the original Bacteric character, but, after seven weeks, the Bacteria had changed from very large to excessively minute ones.

Another species, seen in the first instance in milk, as about the most minute form of Bacterium the author had ever observed, grew in Pasteur's solution as an ordinary full-sized Bacterium; but in urine it assumed the unjointed and cork-screw shape, and the spiral movements of a Spirillum. In turnip infusion it grew with extreme rapidity as an ordinary double-rod-like moving Bacterium, but after remaining some weeks in that medium it assumed a remarkable fungoid character with greatly increased

* Continued from p. 214.

diameter, which on introduction into urine reproduced the moving Spirillum, now of very large size, and sometimes remarkably branched, but as time passed gradually growing a smaller and smaller progeny as the liquid became vitiated, till at length it lost in the urine its spiral shape, and returned to the appearance of the minute ordinary Bacterium first seen in the milk. These may serve as samples of this class of observations, which proved on the one hand how utterly fallacious are any descriptions hitherto given of Bacteria according to form, size or movement, yet, on the other hand, showing that the different Bacteria, like the different Oidia, retained amid all their variations their distinct specific characters.

The fermentative changes induced in the media by the introduction of the various organisms were next alluded to. The test-tubes of the experiment with unboiled milk were shown, and it was pointed out that each different organism was accompanied by a different appearance of the milk, implying that each was associated with a special chemical change in the fluid in which it grew. An enlarged sketch was also exhibited of the boiled milk glasses as they were seen some weeks after they had been inoculated with the various Bacteria, showing that no two of those glasses were alike. In that containing the Bacteria derived from a drop of tap-water introduced into urine the milk had changed to a beautiful green colour; that with the kind which formed the Spirillum in urine was a pure white curdy mass, sharply acid to test-paper, while a third, inoculated with a curious irregular form of Bacterium from another of the milk-flasks, was of umber brown colour. This glass was brought to the meeting because it was of especial interest, not only on account of its peculiar tint, but because it was an instance of a primary alkaline fermentation of milk. Another milk glass had been inoculated with the same organism, and had undergone the same change, assuming in a few days the same umber brown colour, accompanied by powerful alkaline reaction. This particular Bacterium was in some forms undistinguishable from pairs of granules of a form of "Granuligera," which occurred in one of the milk glasses associated with the large Bacteria above mentioned; but the Granuligera having been obtained unmixed by introducing it successively into liquids which permitted its growth, but not that of the Bacterium, it proved to be a feeble acid ferment of milk, not producing any effect upon its colour. One of the glasses sketched was of peculiar interest, because it contained a large motionless Bacterium, which had been the sole product of exposure of a glass of the boiled milk for an hour in a sitting room, the fungus spores that in all probability entered with it having been prevented from developing by the growth of the Bacterium. It happened that the Bacterium thus derived from the air refused to grow in Pasteur's solution, urine, or turnip infusion, so that if the experiment had been performed with either of those fluids, it would have afforded negative results as regards the Bacterium, though fungi would probably have appeared; and this might have been quoted as a good illustration of absence of Bacteric development after atmospheric exposure.

The Oidium, which, as before mentioned, was a powerful putrefactive ferment of urine, produced scarcely any effect on milk, which had remained unchanged in flavour for seven weeks, although converted into a thick mass, not by coagulation of the casein, but simply by the dense jungle of the fungus filaments, while test paper indicated merely a very faint increase of alkaline reaction. The fluid remaining thus unimpaired in quality, explained the luxuriant growth and healthy appearance of the fungus in it, contrasting strikingly with its characters in urine, in which it rapidly occasioned putrefaction, and then formed merely a scum of toruloid rounded cells.

In describing these facts, the author did not affect the circumlocution that would be necessary in order to avoid using the language of the germ theory. As stated at the outset, his original object in the investigation had not been to prove that theory, but to throw light upon the nature and habits of the fermenting organisms. Nevertheless, for the sake of any who might still entertain doubt upon the question, it might be well to point out that the facts which had been adduced were irreconcilable with any other view. It was plain that they utterly disproved the oxygen theory, while they indicated with sufficient distinctness that all instances of so-called spontaneous generation had been due simply to imperfect experimentation. It remained to consider shortly the only other rival theory, the somewhat specious one of chemical ferments. After pointing out some of the inconsistencies of that theory with the facts observed, and how its difficulties became increased with the discovery of every new organism with its corresponding chemical change, requiring the assumption of a new and purely hypothetical chemical ferment, the author reminded the Society that in truth there was not a fact in chemistry to favour the belief that any substance destitute of vitality possessed the one faculty which distinguished all true fermentation, viz. the property of self-propagation of the ferment. Perhaps the most remarkable instance of a chemical ferment was the resolution of the amygdalin of the bitter almond into the essential oil of bitter almonds, hydrocyanic acid, formic acid and glucose under the influence of emulsin. The amygdalin neither gained nor lost a single atom, but was simply broken up into new compounds under the influence of the peculiar albuminous principle emulsin. But did the emulsin undergo multiplication as in the true fermentations? On the contrary, it had been shown by Liebig and Wöhler in their original paper * that a certain weight of emulsin would only break up a limited quantity of amygdalin, and that the emulsin when afterwards separated no longer affected amygdalin. So far from having the property of self-propagation, it lost its catalytic power in the act of catalysis. Thus the chemical ferment theory was in truth utterly destitute of scientific basis as explaining true fermentation.

Such being the case it was contended that the germ theory must now be regarded as demonstrated; viz. that putrefaction and other true fermentations characterised by indefinite multiplication of the ferment are caused by the growth of living organisms, which, while capable of great variations according to the circumstances in which they are placed, retain their specific characters like larger plants, and like them spring only from pre-existing similar organisms.

Nevertheless the so-called chemical ferments had a high degree of interest in this question, as very likely playing an important part in bringing about the chemical changes. For just as it was proved that a peculiar albuminous principle, emulsin, existing in the sweet as well as in the bitter almond, but absent from the pea, or bean, or other leguminous plants examined by Liebig and Wöhle, could break up as much as ten times its weight of a stable crystallisable substance like amygdalin, so it seemed probable that other peculiar albuminous principles might exist in other plants, such as the fungi, and in like manner break up larger or smaller quantities of other stable organic compounds. In this sense, then, as intervening between the growth of the organisms and the resulting decompositions, the theory of chemical ferments might be welcomed as a valuable hypothesis.

Lastly, the author showed some blood obtained from a horse between three and four weeks previously, in the hope that by exposing the carotid artery antiseptically, and receiving the blood from it into a "heated" vessel, and protecting it from dust, he might, after the clot had contracted, decant off the clear serum, and inoculating or exposing the uncontaminated fluid, observe organisms and fermentations corresponding to those which occur in the practice of surgery.

But to his great surprise day after day passed without the clot showing any sign of shrinking, and it remained still uncontracted. In the flask shown, the buffy coat was seen to be present on the upper part of the still tremulous jelly-like coagulum, but instead of being powerfully pinched together into a comparatively small bulk bathed with serum, that part like the rest of the clot was everywhere in contact with the sides of the glass, and not a drop of serum was to be seen. At the same time there was no smell whatever about the cotton that covered the neck of the flask, showing that putrefaction had been avoided. Somehow or other the exclusion of living organisms, while it had not interfered with coagulation, had prevented the fibrine from acquiring a tendency to shrink. This fact, while entirely new, and opening up a wide field of inquiry, was seen to tally with phenomena met with in surgical practice, such as the absence of shrinking of the plug of clot near a ligature placed upon an artery. It was an illustration of how little we are often able to predict what may arise when even the most familiar objects are placed in new circumstances.

SCIENTIFIC SERIALS

THE *Journal of Mental Science*, July.—We have heard or read of a rather impressionable gentleman who, as he perused Dr. Buchan's "Domestic Medicine," fancied himself afflicted with

* *See* "Annales de Chimie et de Physique," 1837, p. 185.

every disorder therein described, not even excepting the pains of pregnancy. Bearing this in mind, we would recommend that none save those well assured of their own sanity should read the *Journal of Mental Science*. There is so much about morbid psychology, madness, and idiocy, that weak readers are in some real danger of being taken possession of by an uncomfortable suspicion that they may be a little touched themselves. The place of honour is given to an address on idiocy by Dr. J. C. Bucknill. This is a piece of special pleading (justified, perhaps, by its occasion) for the education of idiots. Now, as these miserable abortions must be kept in life because of the *indirect* evil effects of any system of extinguishing them, we certainly desire that they should be kept in asylums and made comfortable. But we cannot even grant that they are "more worthy of our efforts than those races of animals which men strive to bring to perfection." Except in so far as Science may be advanced by such work, it seems very much of a waste of time for such a man as Séguin to labour for four months to fix the eye of an idiot as the first step in the education of sight. We cannot go into ecstacy on hearing that idiots are actually taught to use knives and forks, when so many rational beings around us have neither knives nor forks to use, nor any use for them. By all means let the charitable support asylums for idiots; but at the same time it should not be forgotten that these poor creatures can never be educated into anything useful or lovely, and that a point is soon reached beyond which further education is misspent labour.—A valuable paper on "The Use of Digitalis in Maniacal Excitement" is contributed by Dr. W. J. Mickle. Next follows, under the title of "Consciousness and Unconscious Cerebration," a rather muddled attempt, on the part of W. G. Davies, B.D., to upset Dr. Carpenter's doctrine of "unconscious cerebration." From this article one might suppose that the views combated were peculiar to Dr. Carpenter and his so-called disciples Dr. Bastian and Miss Cobbe, whereas in truth the writer has against him not these only, but also the most distinguished of living psychologists. His writing is a good deal in the bad old style, the language serving at times, as it seems to us, to obscure rather than express thought. Dr. Carpenter is accused of imagining a nervous anatomy to suit his theory. But Mr. Davies does not himself seem to be up with the latest scientific surmises. For example, in laying the groundwork of one of his own arguments, he says: "The very same cells in the visual sense-centre cannot, at one and the same moment, see brown and yellow." He does not seem to be aware that it is highly probable that the cells that see one colour never do see another. There are over a dozen other papers, all of more or less, some of them of considerable interest.

THE *Monthly Microscopical Journal* for this month commences with an article by Mr. J. W. Stephenson on the optical appearances presented by the inner and outer layers of Coscinodiscus when examined in bisulphide of carbon and in air, in which the importance of considering the refractive index of the medium in which calcareous and silicious structures are examined, is fully discussed. This is followed by a paper on some new diatoms from the harbours of Peru and Bolivia, by Mr. F. Kitton, in which *Aulacodiscus formosus* and *Omphalopelta versicolor* are the most important.—Mr. F. Wenham, in a very temperate manner, rebuffs the unjustifiable statements of the American microscopists, who, not realising the high scientific position he holds in this country, accuse him of acting unfairly to Mr. Tolles, and insinuate that he has acted from mercenary motives. He ends by saying, "I trust that Colonel Woodward, having affirmed that 'the position taken by me is certainly true for objectives, as ordinarily constructed,' will allow that this additional lens embodies a deviation from the ordinary question, which was to the effect that there would be no loss of angle aperture of ordinary objectives by the immersion of the front surface in fluids."—Dr. Braithwaite continues his observations on the bog-mosses.—Dr. Royston-Piggott considers the high-power definition of minute organic particles, in which he divides his subject into five parts, including the nature of the least circle of confusion, the nature of mixed shadows, and the nature of perfect definition.—The preparation of the brain and spinal cord for microscopic examination, forms the subject of a paper by Mr. H. S. Atkinson, in which he explains in detail the methods employed by Professor Rutherford, and the means of staining sections adopted by himself.

Petermann's Geographische Mittheilungen, No. VI.—An account of Dr. Nachtigal's travels in Northern Africa, which appears in this number, we have already noticed in the advanced sheets One of the longest and most valuable papers is by Dr. C. E. Meinicke on Dr. Bernstein's explorations in the Northern Moluccas, accompanied by a map. An important article is the second part of an account by Freiherr F. von Richthofen, of some of the results of his journey from Pekin southwestwards through China, embracing valuable details on the geology, topography, and natural history of the little known interior of that country. Another important article is on the Aurora Borealis, by M. E. Pechuel-Loesche, who for the purpose of ascertaining the real nature of the phenomenon, brings together the results of the observations of those who have carefully observed it in the Polar regions. This is to be followed by another paper in the same direction.—Dr. H. Wagner contributes an article on the Development of the German Railway System, accompanied by a well-constructed map.

A VERY interesting number of the *Bulletin Mensuel de la Société d'Acclimatation de Paris* has been published for May. One of the principal papers is a long article by the Abbé Desgodins, missionary at Yer-ka-lo, on the zoology of Thibet. The varied temperatures of its different levels are such that the country contains a great variety of animals, the fauna of both tropical and cold climates being found there. A description is given by M. Robert of his patent artificial incubators for hatching eggs, which seem to be more perfect in all their details than any of those appliances we have seen. As a proof of the usefulness of such a Society, the secretary calls attention to the increased price of certain animal and vegetable products of foreign countries, which, if the principle of acclimatisation were more fully developed, could be produced much cheaper in France. Experiments on sericulture have shown that silk of varied colour can be produced by feeding the silkworm on different leaves. Worms fed on vine leaves produce a silk of a magnificent red colour. Lettuce has been found to produce an emerald-green coloured silk. During April, 51 animals and 886 birds were received at the Gardens of the Society, while 51 animals, and 1,333 birds were distributed. Among interesting items of intelligence we may mention that the ostriches have begun to lay, and it is hoped that kangaroos may be so freely bred in France as to justify their being turned loose in suitable parts of the country. Three Trumpeter Swans were received from America.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, June 19.—"On a tendency observed in Sunspots to change alternately from the one Solar Hemisphere to the other." By Warren De La Rue, D.C.L., F.R.S., Balfour Stewart, LL.D., F.R.S., and Benjamin Loewy, F.R.A.S.

1. Hitherto in our reductions we have summed up the spotted areas of the various groups occurring on the sun's surface on any day, and have regarded their sum as a representation of the spot-activity for that day. It has occurred to us to see what result we should obtain by taking instead for each day the excess of the spotted area in the one solar hemisphere above that in the other.

2. On adopting this method, it soon became evident that during periods of great disturbance there is a tendency in spots to change alternately from the north or positive to the south or negative hemisphere, and *vice versâ*, the period of such change being about 25 days. When, on the other hand, the solar disturbance is inconsiderable, the spots do not present any such systematic oscillation.

3. We have graphically represented on a diagram the results derived from this method during three of the most considerable periods of solar disturbance.

In this diagram the observed values of hemispherical excess are marked with an asterisk, and a curve is drawn so as to equalise their smaller irregularities. The northern hemisphere is reckoned positive, and the southern negative. The unit of area is, as before, the one millionth of the sun's visible hemisphere.

4. The first of these three periods extends from the beginning of August to the end of December, 1859. We derive from our diagram the following Table, exhibiting the maximum amounts of hemispherical excess, with their respective dates:—

Date.	Hemispherical excess. North.	South.
1859, July 31	+4180	
Aug. 18		(+ 40)
Aug. 27	+2580	
Sept. 11		−2920
Sept. 17	+ 920	
Oct. 3		−1420
Oct. 16	+1000	
Nov. 3		−2480
Nov. 15	+ 120	
Nov. 20		−1320
Dec. 7	+1050	
Dec. 22		−1400

From these we derive the following values of a period of oscillation by taking the differences in dates between the positive extremes :—

27 days, 21 days, 29 days, 30 days, 22 days—mean, 25·8 days ;

while doing the same with the negative extremes, we obtain :—

24 days, 22 days, 31 days, 17 days, 32 days—mean, 25·2 days.

5. The second of the three periods extends from the end of June to the beginning of November 1860. Treating this in the same manner, we obtain :—

Date.	Hemispherical excess. North.	South.
1860, July 1	+4900	
July 22		− 600
July 30	+2040	
Aug. 9		−2400
Aug. 21	+ 400	
Sept. 5		−1400
Sept. 16	+ 400	
Oct. 1		−1180
Oct. 9	+ 800	
Oct. 19		−2560
Oct. 31	(− 380)	

From these we derive, by taking the differences in dates of the positive extremes,

29 days, 22 days, 26 days, 23 days, 22 days—mean, 24·4 days ;

while doing the same with negative extremes, we obtain :—

18 days, 27 days, 26 days, 18 days—mean, 22·25 days.

6. The third of these three periods extends from the beginning of May to the end of August 1862. Treating this in the same manner, we obtain :—

Date.	Hemispherical excess North.	South.
1862, May 9	+ 600	
May 22		−1160
June 3	+2960	
June 15		−2600
June 29	+1880	
July 16		−800
July 26	+2400	
Aug. 14		− 200
Aug. 23	+ 460	

Taking, as before, the distances between the positive extremes, we obtain :—

25 days, 26 days, 27 days, 28 days—mean, 26·5 days ;

while from the negative extremes we obtain :—

24 days, 31 days, 29 days—mean, 28·0 days.

From the whole three periods we obtain, as the most probable mean value, 25·2 days.

7. We do not profess to have discovered the cause of these oscullations, but we would nevertheless suggest that the observational facts here brought to light may perhaps be connected with two other observational facts, the one of which was first brought to light by Carrington, and the other by ourselves.

The first of these is the fact that, generally speaking, spots in the north hemisphere have much about the same latitude as those occurring at the same or nearly the same period in the south, both sets widening or contracting together. We may perhaps, therefore, suppose, by applying this law, that the latitude of the spots which cause the positive extremes in the above series is not greatly different from that of those which cause the corresponding negative extremes.

The second observational law is that which tells us that spots about the same period have a tendency to attain their maximum at or near the same ecliptical longitude. Now, if we suppose that in the foregoing three series the greatest positive extremes were caused by the positive spots attaining their greatest size, and the greatest negative extremes by the negative spots, attaining their greatest size, it would follow that the two sets, positive and negative, must have taken their rise at places on the sun's surface 180° of longitude different from each other inasmuch as the one set about twelve or thirteen days before or after passed (let us say) the same ecliptical longitude as the other.

But if the positive set have the same latitude as the negative, and if the one is 180° of solar longitude different from the other, it would mean that *the two outbreaks are at opposite ends of the same solar diameter*.

This conclusion is an interesting one, but, of course, it requires to be verified by further observation before it be finally received. Meanwhile, we are engaged in mapping out systematically the positions of the various outbreaks of the sun's surface, and we shall soon, therefore, be able to find whether or not there be any truth in this conjecture.

Geologists' Association, July 4.—Mr. Henry Woodward, F.R.S., president, in the chair.—1. "A sketch of the Geology of Northamptonshire," by Samuel Sharp, F.S.A. A general section of the county of Northampton shows the lias as a basal formation with the inferior oolite beds of the "Northampton sands" above. Fossils are abundant, and some species are not found in other localities. The upper division consists of a nearly white siliceous sand with bands of clay and a plant bed, the whole of these deposits being evidently of estuarine and littoral origin. Above these, but unconformably, lies the bed classed as Great Oolite, and which consists of, firstly, a series of clay beds with a ferruginous base and containing a plant bed ; then, secondly, a limestone series abounding with fossils and affording an ornamental stone called "Alwalton marble." The bed of clay reposing on these great oolite strata may be considered the equivalent of the "Bradford clay," and still higher in a general section will be found the Forest marble, the Cornbrash, and, highest of the secondaries, the Oxford clay. The high lands of the county are frequently capped by boulder clay and glacial gravels containing fragments from nearly the whole series of the primary and secondary rocks. A peaty fluviatile bed above the gravels contains at its base numerous remains of mammalia. The lias extends throughout the county though appearing only in the valleys, the iron sands occupy the middle and the Lincolnshire limestone the northern portion of the county, while the other formations are patchy in extension. A high table-land about Naseby gives rise to the Avon, the Welland, and the Nene, which occupy the principal valleys of the county. In past times efforts were made at considerable cost to find coal, and recently the question of whether coal can be obtained in the county has been discussed, but judging from what we know of the rocks of the nearest coal-field of Warwickshire, and of the intervening district, as much as 4,500 ft. of strata may lie above coal-seams of sufficient thickness to be worked. Moreover, Prof. Hull, F.R.S., concludes that "Carboniferous" coal will not be found at any depth in Northamptonshire.—2. "On some new Crag Fossil," by Alfred Bell. The author's observations since his former paper on the crags was read, confirm the views he then expressed as to the divisibility of the English crags into four divisions founded on palæontological evidence. He had determined 145 species (some new, some new to the crag, and some new to particular divisions) in addition to those given in his published lists.—3. "An account of the Eruption of Mount Vesuvius of April 1872," by J. M. Black. In this paper the brief but violent and destructive eruption of last year was described by the author, who has carefully noted the various phenomena that occurred during its continuance. An ascent of the volcano was made by Mr. Black, a few days after the eruption, and the form and condition of the crater observed. The author had succeeded in photographing various parts of the mountain after the eruption, and the views so taken were exhibited.

PHILADELPHIA

Academy of Natural Sciences, April 1.—Dr. Ruschenberger, president, in the chair. The following paper was presented for publication :—"On the Affinities of the Sirenians," by Theo. Gill. Prof. Leidy remarked that the rat presented this evening by Mr. L. Fussel was a specimen of the Black Rat, or *Mus rat-*

tus, which had been caught on board a ship in the vicinity of the city. This rat is exceedingly rare, but is said to have once been common enough, and is also said to have been nearly exterminated by the common brown or Norway Rat.

April 8.—Dr. LeConte announced the death, at Davidsburg, York Co., Pa., on March 10, of Freidrich Ernest Melsheimer, M.D., a correspondent of the Academy, aged nearly ninety-one years. He inherited great taste for entomology from his father, E. F. Melsheimer, a clergyman, who cultivated natural science with much success, and not only was a highly esteemed correspondent of Knoch and other European entomologists of the end of the past and beginning of the present century, but an active collaborator with Say, the founder of descriptive entomology in the United States. Entomology also owes to Dr. Melsheimer the catalogue of the described Coleoptera of the United States, which was published by the Smithsonian Institution in 1853. It was the first work of bibliographical importance in the modern history of that branch of science, and gave a powerful impetus to its development in the United States, and has greatly diminished the labour of those who have continued the study of that department.

April 15.—"Observations on a Change of Structure of a Larva of *Dryocampa imperialis*," by Thos. G. Gentry.—"Remarks on Extinct Mammals from California. Prof. Leidy directed attention to some fossils, which he had borrowed, through Prof. E. O. Hovey, from the cabinet of Wabash College, Crawfordsville, Indiana. The most interesting specimens consist of an upper molar and a complete lower molar series of a lama as large as the existing camel. Remains of a still larger species from California have been previously indicated under the name of *Auchenia californica*. The present specimens were referred to a species with the name *Auchenia hesterna*. Prof. Owen has described some remains of an equally large lama from Mexico, which he refers to an allied genus with the name *Palauchenia magna*, and which perhaps may be the same as the *Auchenia hesterna*. An inspection of Prof. Owen's figures of a series of molar teeth leads to the suspicion that he has inadvertently mistaken the upper series for the lower ones, and has thus been led to refer them to a genus different from *Auchenia*.

April 22.—"Influence of Nutrition upon Sex among the Lepidoptera," by Thos. G. Gentry.—"Fungus Parasite on a Mouse." Prof. Leidy exhibited a mouse with several whitish masses adherent to the ears, side of the face, and nose. The mouse had been caught in the children's department of Blockley Hospital. The white matter examined beneath the microscope proved to be composed of sporular bodies, single, double, or in short chains of a dozen or more. They measure about the $\frac{1}{810}$ of a line in a diameter. The fungus is a Torula or Oidium, and resembles that found in Aptha. Perhaps the disease in the mouse is the result of feeding upon articles imbued with adherent portions of apthous matter from the mouths of children.

BERLIN

German Chemical Society, June 24.—C. Rammelsberg, vice-president, in the chair.—F. Römer has investigated the following derivatives of normal propylic alcohol:—The mercaptan and its mercury-compound, propyl-xanthogenic acid and its sodium salt, and the monamine. By heating cyanate of potash with propyl-sulphate of potash no cyanurate of propyl was formed, but a well-crystallised biuret in which three atoms of hydrogen are replaced by three molecules of propyl.—R. Otto sent a well-crystallised specimen of phosphate of ammonium and magnesium from the cesspool of an old house in Brunswick, analogous to the crystals of "Struvite" found in Hamburg in 1842.—C. Scheibler showed a specimen of glass ground by a new method, which has come to us from America, and is now practised in the glassworks of M. Hasenclever at Hollberg, near Aix-la-Chapelle. By means of Giffard's injector a current of fine hard sand is thrown with great force on the glass, which is thus ground; but any pattern cut in paper and pasted on the glass remains unaltered. Even hard minerals, such as corundum, can be ground by this process.—C. Böttinger has studied the action of baryta on pyruvic acid. According to Finck two acids are thus produced, one crystalline, which he called uritinic, and one syrupy body, to which he gave the name of uritonic acid. Mr. Böttinger's researches throw doubts on the existence of the latter body, which seems to be a mixture of uritinic, acetic, and oxalic acids.—C. Rammelsberg communicated new researches on the composition of vesuvians of different origin.—W. H. Pike, of London, has treated sulfo-urea with chloride of benzoyle, obtaining well crystallised benzoyle-sulfo-urea $(C_7H_5ONH)CS(NH)_2$ of the melting-point 170°.

PARIS

Academy of Sciences, July 7.—M. de Quatrefages, president, in the chair. The following papers were read:—New clinical researches on the localisation, in the anterior lobes of the brain, of the action by which the brain contributes to the psycho-physiological faculty of speech, by M. Bouillaud. At the conclusion of this somewhat long paper, M. E. Chevreul made some remarks on Dr. Bouillaud's conclusions.—On the exponential function, by H. Hermite.—On the heat of combination referred to the solid state, a new expression for thermo-chemical reactions, by M. Berthelot.—The election of Dr. Carpenter, Mr. Steenstrup, and Mr. Dana, as recorded in our notes, then took place.—On a system of optical telegraphy, invented during the siege of Paris, by a commission appointed by the Governor, by M. Laussedat.—On the nutritive and milk-producing properties of *Galega officinalis*, by M. Gillet-Damitte.—On the constitution of the sun and the theory of the spots, by M. E. Vicaire. The author vigorously supported the scoriæ theory of spots, which he regards as formed by the fall of heated products of combustion into a boiling liquid; he considers that the prominences are formed at the same time and by the same agency.—Solar cyclones compared to those of our own atmosphere, by M. H. Tarry.—On a new isomer of valeric acid, by MM. Friedel and Silva.—On the transformation of succinic into malic acid, by M. E. Bourgoin. The author has succeeded in effecting this by heating fine and dry argenetic malate, mixed with fine sand, to 180°.—On the mode of decomposition of explosive bodies as compared with the phenomena of supersaturation, by MM. Champion and Pellet.—On the action of benzyl chloride on napthalamine, by MM. Ch. Froté and D. Tommasi.—Experimental researches on the action of nitrous oxide, by MM. F. Jolyet and T. Blanche. The authors believe that this gas is not a true anæsthetic, but acts by producing asphyxia.—Researches on the floral organogenesis of the hazels, by M. H. Baillon.—Discovery of the makis and the horse in the fossil state in the phosphorites of Lot, by M. E. Delfortrie.—On the crystalline forms of Scotch Lanarkite, by M. A. Schrauf.—Details of the earthquake of the 29th of June, by M. W. De Fonvielle.

THE ENDOWMENT OF RESEARCH
III.

IT is probable that though the main proposition here advocated, that original workers in the Sciences deserve, on public grounds, a recognised position and pecuniary support, will not meet with much opposition from any quarter, the means by which this desirable end is chiefly proposed to be attained will not be acquiesced in with equal readiness. Englishmen have been so long accustomed to regard their Universities as merely high schools of liberal education, and the independent growth of modern Science in this country has been so rapid and vigorous, that to many worthy persons it will seem nothing better than a Utopian dream to attempt to re-establish the genuine pursuit of scientific knowledge as an end in itself at our ancient seats of learning. Those, however, who know something about the system of a German University, and are acquainted with the former history of Oxford and Cambridge, will not consider the attempt to be of such a hopeless character. The present time also affords an admirable opportunity of urging upon public attention a fundamental reform in the direction above indicated. The Universities have of late years been losing many of the peculiarities which they once so warmly cherished, and at the same time their revenues have been increasing to an enormous extent. The same Government which passed a Bill to pronounce them national and not ecclesiastical establishments, has also issued a Royal Commission to inquire into the extent and distribution of their endowments. Now that the nation has established its claim to remodel the Universities solely with a view to the public interest, and is taking stock, as it were, of the property which has fallen under its disposal, the very occasion has come when scientific men should formulate their demands on behalf of those public interests which the practical politician is likely to neglect. It must, moreover, be borne in mind that the impulse in this direction must come from without, for although it will not be difficult to prove that no less benefit would accrue to the Universities themselves than to the cause of Science from the scheme herein advocated, yet the most advanced academical reformers do not seem to have got beyond the notion of extending and perfecting the professorial functions.

We propose then to show at some length that the Endowment of Research should naturally take a leading place in the reconstruction of the University system which appears to be close at hand, and to indicate in what manner such endowment may most readily be carried into effect. For this purpose it will not be necessary to reveal the many minor abuses which the reforms of twenty years ago failed to remove, but it will be necessary to adopt the more difficult task of sketching out the true conception of what a University should be, and of considering the comparative claims to endowment of teaching and of study.

Without any attempt to prejudge the matter, or to awake the dormant controversy as to the original meaning of the word, it may be safely laid down that a University is an institution composed of the most competent teachers and the most promising students, on which the State, in consideration of its diligently promoting the higher education, confers a lofty position and important privileges. That such an institution should enjoy large endowments is evidently not of the essence of its nature, for the Universities of old were uniformly most famous when they were least rich: it is, however, absolutely necessary for the healthy activity of its functions that it should not be so encumbered with wealth as to be disposed to lavish sinecures upon its favourite members. It is evident, also, that it will forfeit its trust as the home of Culture and of Science, and will degenerate into a lyceum for the adult sons of the well-to-do classes, unless it continually maintains itself on a level with the ever-advancing boundaries of human knowledge, and that just so far as it lags behind it will exercise a mischievous influence on the simple public, who continue to rely upon its treacherous authority. Further, it is of great importance that the original institution, on which alone the rank was bestowed, and which alone deserves the high privileges, should not be absorbed by the growth of a number of parasitic institutions, whose interests and aims may be not identical with or even analogous to its own. But above all other symptoms of decay that a University can show, is to be placed its rejection of the highest branches of knowledge which the progressive activity of human thought is ever comprehending within the domain of Science. To this danger the most ancient and the most wealthy Universities are naturally the most exposed. Their antiquity leads them to regard the erudition which they have inherited through many centuries as synonymous with real knowledge, and their wealth is used (where it is not misused) to afford encouragement only to those kinds of learning which their traditions have sanctified. In brief, a false University would be an institution which is content merely to satisfy the demand for teaching which custom approves, and which neglects as a hindrance to its tuitional duties the higher knowledge which it was originally founded to promote.

To recall such a University to the true conception of its duties no mere mechanical changes with reference to its internal organisation will be sufficient. It has lost the spirit of disinterested study which first gave it life, and the atmosphere of intellectual activity under which alone it can flourish. It requires that new vigour should be poured into it, and a new order of workers established within its limits. It requires to be relieved of the burden of part of its wealth, in order that it may receive back again greater advantages than it can give. By endowing research in all those departments of knowledge to which the scientific method has been already extended, and by reserving the power of similar endowment for those other departments of knowledge which will, no doubt, before long be similarly reduced to order and law, Oxford and Cambridge may yet regain the proud position which was once theirs, as "bodies of learned men devoting their lives to the cultivation of Science, and the direction of academical teaching."

To point out more particularly the source from which the endowments of research should be drawn, it will be necessary to revive the original distinction between the Universities and the Colleges of which they may be said to be now composed. To raise the University proper at

the expense of the individual Colleges, has long been a favourite project with academical reformers, yet no one yet appears to propose any more radical scheme than an augmentation in the number of University Professors, and a diminution in the influence of College tutors. Against any such scheme, however carefully elaborated, there arise the old objections that an improvement in the mechanism of teaching is not the main reform of which the Universities stand in need, and that the endowment of more teachers will not remedy the crying evil which has so lamentably hindered the advance of purely scientific investigation in this country. The circumstance that the Universities are comparatively poor, while many of the Colleges are very rich, and an awakening conviction that the Colleges exist for the Universities, and not the Universities for the Colleges, would seem to have suggested the above proposal: whereas the smallest historical knowledge of the objects with which the Colleges were originally founded, would reveal the curious circumstance that the first benefactors had a truer conception of the manner in which knowledge ought to be endowed, than have the modern recipients of their benefits. Nothing can be more certain, though nothing is more frequently denied by those whose duty it is to be better informed, than that the majority of the great Colleges were not founded to be boarding schools for teachers and students, subordinate to the University curriculum, but to be homes at the central seats of learning, where life-long students might be supported while acquiring all the knowledge of the age, and augmenting the store of learning which they had there inherited. According to the old Oxford tradition, she could boast in the fifteenth century before there was ever a wealthy College that she had thousands of students living in hundreds of private halls. Many of the early Colleges did not include at all in their arrangements those whom we should now call Undergraduates, some of those which did do so allowed for a teaching staff independent of the body of Fellows, and it is within modern memory that many Colleges have had more Fellows than Undergraduates on their books. All these facts, and there are many similar ones, go to prove decisively that, in the language of Mr. Mark Pattison, "the Colleges were in their origin endowments not for the elements of a general liberal education, but for the prolonged study of special and professional faculties by men of riper age: and that so far from it being the intention of a Fellowship to support its holder as a teacher, it was rather its purpose to relieve him from the drudgery of teaching for a maintenance, and to set him free to give his whole time to the studies and exercises of his faculty." The wish of the Founders, that is to say, when harmonised with the wants of the present age, and interpreted into the language of modern science, was to afford the means of living and the instruments of work to those who pledge their lives to the unremunerative task of scientific investigation, and original research.

Surely then, if the influential and wealthy members of our Universities have at heart the real interest of their Institutions, or retain any veneration for the express intentions of their benefactors, they should not be the last to join in the patriotic object of raising the scientific reputation of this country, and increasing in manifold unseen ways the elements of our national greatness. C.

ALEXANDER VON HUMBOLDT

Life of Alexander von Humboldt, compiled by F. Löwenberg, Robert Ave-Lallemant, and Alfred Dove. Edited by Professor Karl Bruhns. Translated by J. and C. Lassell. 2 vols. (London: Longmans, 1873.)

WE cordially welcome this admirable translation of the only biography of A. v. Humboldt that has yet appeared possessing any authentic or scientific value. Humboldt's own definitely expressed aversion to biographical notices, whether in regard to himself or his friends, the fact of his having outlived nearly all his blood-relations and the greater number of the contemporaries of his earlier working years, together with other causes, combined, for a time, to retard the appearance of a trustworthy life of this remarkable man.

The want of such a work was, however, strongly felt, and at the Congress of Astronomers convened at Vienna on Sept. 14, 1869, in honour of the centenary of A. v. Humboldt's birth, Dr. Karl Bruhns, Director of the Observatory at Leipzig, laid before the meeting the prospectus of a Scientific Biography of their great countryman, for which he demanded their active co-operation. The result of this appeal and of his own editorial labours, was the appearance last year, in Germany, of the work of which the present excellent translation gives us two volumes. The third volume of the original, which consists of critical *résumés* by various writers of the state of different branches of the physical and natural sciences, with notices of Humboldt's contributions to each, has been omitted by the translators, on the ground that the facts were treated of with sufficient minuteness in the general biography. On less good grounds, as it appears to us, they have also omitted from the last section of the second volume, the comprehensive catalogue of his published writings, of which upwards of 600 are enumerated in this list.

Humboldt's life, like the work devoted to its exposition, resolves itself into two distinct parts or periods. The first of these is characterised by intense and incessant activity in the acquisition of knowledge, the second by the quiet mature elaboration of the results of earlier study and observation ending in a thirty years' term of comparative stagnation under the depressing influences of honorary court servitude.

Alexander v. Humboldt was born at Berlin, in 1769, and together with his elder brother Wilhelm, was prepared under excellent private tutors for his university career at Frankfort, A. O., where he matriculated in 1787. He had already then shown that craving for the accumulation of facts which he retained to his latest years, and from his boyhood had been distinguished for his love of observing and collecting natural history objects, and his inaptitude for acquiring the exact classical scholarship for which his brother evinced such marked ability. Botany was Alexander's first love, and the earliest of his voluminous literary productions was a treatise in French which appeared anonymously at Berlin, in 1789, in the *Gazette Literaire*, entitled, "Sur le Bohon-Upas, par un jeune Gentilhomme de Berlin." This composition was, however, rapidly followed by papers on the flora and geology of the Rhine lands, and other districts which he visited in the course of the few short intervals of cessation

from study which mark his university career, and b numerous essays on mathematical, physical, medical, physiological, and even *classical* subjects; for by dint of hard work he had, during his attendance on Heyne's Greek lectures at Göttingen, so thoroughly mastered his earlier deficiencies that he won from that learned professor the distinction of being commended as "a better philologer than any who had left the class for many years." The University of Göttingen to which the brothers had migrated in 1789, and which had already begun to attract students from all parts, as the best school of pure and practical science, afforded the advantages that Frankfort had failed to give them; and here, under Lichtenberg Gmelin, Osiander and Blumenbach, Alexander laid the solid foundations of those varied acquisitions in the departments of physical and natural science, which justly entitle him to rank as the greatest pioneer in the cause of modern research. Others may have very far surpassed him in one or more domains of inquiry, but no one man in his time has done more than A. v. Humboldt in accumulating materials, testing evidence, repeating experiments and carrying on observations in almost every section of knowledge by which the labours of subsequent inquirers have been lightened. To his latest years, Humboldt did justice to the benefit which he had derived from Göttingen, which he had entered with "the *unusual* advantages," as we are told by his former tutor, the mathematician, Fischer, "of having received an excellent education, and of possessing a proficiency in mathematics which might have secured him distinction had he been able to devote his attention exclusively, or even partially, to that science." Political economy had, however, already become the principal object of his studies, in consequence of his having made choice of the public bureaucratic service of the State as his future career. In 1790 his experiences of foreign travel were begun during a visit to England, made in company with George Forster, the friend whose adventurous voyages and various books of travel had given Humboldt from his earliest boyhood the keenest desire to visit tropical lands, and see with his own eyes the exotic floras and faunas which he described in such glowing colours. The journal which records the experiences of this tour gives evidence of the astonishing range of information possessed at this time by Humboldt, who, true to his destined vocation, set himself steadily to work to observe everything bearing upon the politico-economical aspects of English life, although his scientific tastes are perpetually cropping out in remarks upon the geological features of the country. To this first experience of English life and to the influence exerted on his future pursuits by intercourse with George Forster and his friends, Humboldt long looked back with grateful pleasure. Soon after his return to Germany he went to Hamburg for the sake of attending lectures on currency, book-keeping, and other practical branches of commercial knowledge at the Academy of Commerce, which, under the management of its chief professors, the jurists Busch and Ebeling, was attracting the attendance of young men preparing for a political career.

From Hamburg A. von Humboldt passed to the Freiberg School of Mines, where, under Werner, he prepared himself for the special duties of the post of Assessor and Superintendent of Mines to which he had for some time aspired, and which for a time after its attainment seemed to him the realisation of all his wishes. No *employé* had ever been more zealous, and all his reports were expansive geognostic treatises on the districts he was called upon to survey. The charm of novelty soon, however, wore off, and then the complete stagnation, the systematised red-tapeism, and the absolute dearth of intellectual or rational interests belonging to Prussian Public Service in those times, proved as unbearable to Alexander as they had already become to his elder brother, and both ceased their official connection with the State at the first moment they could do so. Society in Berlin was equally distasteful to them on account of the prejudice and etiquette by which it was regulated, and after a prolonged and happy sojourn at Jena and Weimar, the then active centres of the true intellectual, æsthetical, and literary life of Germany, Alexander proceeded, on the death of his mother in 1796, to carry out his long-cherished dream of visiting far distant tropical regions. To prepare himself thoroughly for this purpose had been for years the object of his studies, and few men were ever better fitted than himself for the end he had in view. To his other qualifications for becoming an efficient scientific traveller, he added the possession of an almost unparalleled range of knowledge, including an intimate acquaintance with the character, history, and resources of his own country, unbounded love of nature, unflinching perseverance, nearly inexhaustible capacity for work, wide sympathies with his fellow-men, a ready gift of pleasing and being pleased, and an ardent, almost ideal enthusiasm, which found expression in his own favourite motto, "Der Mensch muss das Grosse und Gute wollen" (Man must strive after the Great and the Good).

After oft repeated disappointments and many shattered plans, A. v. Humboldt, in spite of the numerous obstacles arising from the disturbed political condition of Europe at the time, achieved his long-cherished project of visiting the New World, and in the summer of 1799 he landed in South America. In the following year he and his companion and friend, Bonpland, plunged into the steaming forests of the Orinoco, and bidding farewell to civilisation, threw themselves into the work before them. An enormous mass of specimens collected from every kingdom of nature preceded A. v. H.'s return to Europe in 1804, and gave the scientific world at home a faint foreshadowing of the gigantic dimensions of the labours accomplished by that indefatigable explorer. Paris was at that time the only spot where a work such as he meditated could be produced, and accordingly thither he repaired, and after securing the co-operation of Cuvier, Latreille, and many of the other leaders of science, proceeded to elaborate his materials. The result of these combined labours was the appearance, in 1807, of the magnificent work known as "Voyage aux Régions equinoxiales du Nouveau Continent fait dans les années 1799 à 1804, par A. de Humboldt et A. Boupland." The cost of bringing out this colossal *résumé* of his American observations involved Humboldt in pecuniary embarrassments, from which he can scarcely be said ever to have freed himself, and which had moreover the disastrous results of forcing him to accept help at a subsequent period from the King of Prussia; and thus incur an obligation which he found

could only be redeemed by devoting himself to the perpetual restraints of a court-life. The times were inauspicious to great literary or scientific undertakings, and hence we cannot wonder that the "Voyages aux Rég. Equinox." should have proved pecuniarily a failure. At that period of political inquietude and financial depression in every part of the Continent, 290*l.* was a very large sum to pay for any work, although, perhaps, not in this case commensurate with the outlay, when we bear in mind that the printing and paper alone had cost 840,000 francs, and that it contained more than 1,400 beautifully coloured illustrations, and consisted of twenty folio and ten quarto volumes, which were, moreover, divided into five distinct parts, complete in themselves, and to be purchased separately. Humboldt had started on his travels with property realising about 500*l.* a year, but the cost of his expedition and of publishing, added to the war requisitions by which the value of his private property had been materially injured, left him for a time on the brink of absolute poverty. These temporary anxieties had, however, little effect on his mental energies; and after the completion of his American voyage, he continued for twenty years to reside at Paris, where his life was passed in one incessant whirl of intellectual labour, scientific discussions and social intercourse. Thus at one time he would spend months together working with Guy Lussac in the laboratory of the Ecole Polytechnique, at another keeping watch day and night at the Observatory, while he was always preparing fresh papers to read before the Institute and other scientific associations, and carrying one or more works contemporaneously through the press. Besides these labours he had early entered upon the study of the Oriental languages with the view of undertaking a scientific expedition into Asia for the purpose of collecting materials for a comparison between the eastern and the western continents. This scheme after many abortive attempts was finally carried out in 1829, when by the munificent aid of the Prussian King and the truly imperial liberality of the Emperor Nicholas, Humboldt found himself able to penetrate at the head of a carefully equipped scientific staff into the Steppes and the remotest parts of Asiatic Russia. The cost of his journey from Berlin to St. Petersburg and back was defrayed by the Prussian Government, whilst a sum of 20,000 roubles was placed at his disposal for his personal expenses by the Emperor, on his arrival in Russia. The results of this great expedition are of very inferior value to those yielded by the American voyages of earlier years.

This comparative failure may be in part referred to the short time—only nine months—devoted to the purpose, during which the veteran traveller passed over nearly 12,000 miles of the Russian territory. The journey was moreover a princely procession rather than a scientific expedition. Wherever he went crowds of local dignitaries, soldiers and police officers surrounded him. Governors of provinces, commandants of fortresses, superintendents of mines welcomed him with speeches and reports whenever he appeared within the limits of their jurisdiction. Generals supplied him with minutes of the strength of the various brigades under their command, while officers and men in dress uniforms saluted him in military fashion as he passed their posts. At Miask these military marks of respect culminated in the presentation, by the directors of the mines, of a grand cavalry sabre, in honour of his sixtieth birthday. The learned bodies were equally on the alert to show him respect. At Kasan, after incessant feasting and speechifying, the Professors escorted him to his lodgings at 1 A.M. in gala costume, and reappeared in the same attire at 4.30 A.M. to speed his departure to the next station. After enduring a host of similarly oppressive social distinctions, which included at Jekatharinenburg the obligation of leading off a ball in a stately quadrille, and on the Steppes at Orenburg the necessity of presiding over a Kirghis festival at which the men ran races and the Tartar Sultanas warbled sweet songs in his praise, Humboldt had to encounter at Moscow one of the most absurd ordeals to which the fame of his greatness exposed him. On his arrival he was invited to attend a special meeting of the Physical Society, and duly made his appearance at the University, holding in his hand the paper he had prepared to read to the learned members "On the deviation of the Magnet in the Ural." The court, passages, stairs, and halls were crowded with great people, gorgeous with stars and orders, amongst whom stood conspicuous the Professors, wearing long swords girded to their sides, and three-cornered hats tucked under their arms. Speeches of welcome in German, French, and Latin from the Governor-General, the chief clergy, and the deans of the various faculties had to be heard and replied to, and instead of engaging in scientific discussion on magnetic aberration, Humboldt had to listen to a Russian poem in which he was hailed as Prometheus, and to examine a plait of Peter the Great's hair, which was solemnly presented for inspection by the Rector of the University. The "Asie Centrale" and a few very fragmentary works were the immediate results of this most oppressively-honoured expedition, from which, satiated with ceremonials and respect, Humboldt had, in the winter of the same year, 1829, returned to Berlin, which thenceforth to the end of his long life in 1859 became his home.

To fully understand the sacrifices to expediency and to the obligations of gratitude made by Humboldt in accepting the position of what may best be termed an honorary *attache* to his own Court and Sovereign, one requires to read with attention the pictures drawn in these volumes of society in the Prussian capital during the earlier half of this century. But it would scarcely, perhaps, be possible in the present changed position of Prussia to realise the deadness and stagnation that then hovered over every phase of social life. Humboldt, who from the year 1809, when he accompanied the Prince of Prussia to Paris in the capacity of friendly and official adviser, had repeatedly been entrusted with diplomatic and other honourable missions by the Sovereign, entertained a warm regard for the different members of the Royal family, while his relations to the late King Frederick William IV. were those of a long-tried, affectionate friendship. These feelings undoubtedly softened the hardships of the courtly bondage in which he spent his last thirty years, but though they may have gilded the bitter pill, they scarcely made it palatable; and Humboldt's voluminous correspondence at Berlin bears ample testimony to the struggle which was going on within himself to keep in check his contempt for Courts, his

natural proclivity to sarcasm, and his impatience of routine constraints. With the view of trying to leaven the dead mass around him, and to awaken some interests apart from everyday life, he gave popular lectures to the upper classes, which ultimately resolved themselves into that very attractive—if slightly prolix—*résumé* of his knowledge, observations, and speculations, which we know under the title of "The Cosmos." And while he laboured assiduously to exercise his influence for the endowment of scientific institutions of all kinds, and the encouragement of learning and learned men, not only in Germany, but in every country where his reputation made his recommendations authoritative, he set his scientific brethren a striking example of patient, persevering industry in trying to keep pace with the rapid progress of inquiry, and of humble readiness in renouncing old opinions whenever he found that they had been superseded by more correct views.

To the English reader interested in tracing the progress of scientific and social development in Germany and other parts of the Continent during the close of the last and the first half of the present century, the "Life of A. von Humboldt, by Bruhns and Lassell," cannot fail to prove at once instructive and suggestive.

STIRLING'S "PHILOSOPHY OF LAW"

Lectures on the Philosophy of Law. Together with Whewell and Hegel, and Hegel and Mr. W. R. Smith, a Vindication in a Physico-Mathematical regard. By James Hutchinson Stirling, F.R.C.S. and LL.D. Edin. (London: Longmans, 1873)

THIS volume contains certain lectures on the Philosophy of Law, delivered to the Juridical Society of Edinburgh in November 1871, together with a discussion of Hegel's opinions concerning gravitation and the differential calculus. Of the lectures we may say, that if the members of the Juridical Society understood them, they must be much more clever than we profess to be. The first lecture is an introduction to philosophy in general, that is, the philosophy of Hegel. It expounds the doctrine of the *notion*, and discloses in the briefest possible space the "secret of Hegel." Mr. Stirling has already written a work of two substantial octavo volumes, entitled "The Secret of Hegel." A friend of the author being found reading it, and being asked what he thought of the "Secret," answered, "Why, I think the author has kept it." If then the secret cannot be disclosed in two volumes, how did Mr. Stirling hope to make it plain in a lecture occupying only fifteen printed pages? In reading this lecture we did not enjoy for a single moment the feeling of solid ground. We had an impression that we understood what logic was until we met with the following passage:—

"Hegel's system, as is now pretty well known, is contained in three great spheres—the Science of Logic, the Philosohpy of Nature, and the Philosophy of Spirit. Here we see at once that what we have before us is the Notion. Logic is the universal; Nature is the particular; and Spirit is the singular. Logic, having developed into full *Idea*, passes into the particular as the particular, into externalisation as externalisation, in Nature; and Nature, rising and collecting itself, through sphere after sphere, from externality itself in the form of space, up to *natural* internality in the form of organic life, passes into the Soul, which is the first form of Spirit. The instrument of the evolution all along, we are to understand, is the *Notion*, in its three *Moments*" (p. 15).

So long as Hegel and his satellite Stirling kept to the *notion* and its three moments in the abstract, they are impregnable and unapproachable, like those fishes which are said to make the water muddy all around when an enemy is near. It was when Hegel ventured out of his own mists that he showed his extreme fallibility. Having applied his "notion" to the theory of gravitation, he discovered that Newton was wrong in asserting the curve of motion of a gravitating particle to be any conic section.

"Hegel's idea certainly is that the ellipse is a necessary outcome of *the notion* on this the stage of free motion according to the relations of time and space as moments. If planets do move in circles, or even if planets might move in circles, Hegel would here have to confess a failure. It would be his metaphysic that in that event would suffer, however, rather than his knowledge of physics. In the meantime, the fact is that the curve of movement still remains an ellipse, and Hegel so far is not in error" (p. 99).

Now, inasmuch as the circle is only the extreme case of an ellipse possessing no eccentricity, it is just as likely that a planet would move in a circle as in any one definite ellipse; but astronomers could never discriminate with certainty between a circle and an ellipse of very slight eccentricity; and so far Hegel escapes absolute conflict with fact. Unfortunately, however, it is known that certain comets move in hyperbolic paths (see Chambers' "Handbook of Descriptive and Practical Astronomy," p. 203, 1861), and as the ellipse is the *necessary outcome* of Hegel's notion, we think he must suffer both in his metaphysics and his physics.

In Mr. Stirling's controversy with Mr. W. R. Smith concerning Hegel's notion of the differential calculus, we also think that Hegel suffers. The critical statement of the necessary outcome of Hegel's philosophy is as follows (p. 113):—

"The limit of a qualitative relation is that in which it both is and is not, or, more accurately, that in which the quantum has disappeared, and there remains the relation only as qualitative relation of quantity."

Now the very essence of the differential calculus consists in the fact that quantities, although indefinitely decreasing, or vanishing, as the expression is, preserve all their quantitative relations. Mr. Stirling says (p. 114):—

"What is called infinitely *little* is only qualitative, and is neither little nor great, nor quantitative at all."

On the contrary, the very principle of the calculus is that infinitely little magnitudes are still comparatively little or great, and preserve all their quantitative relations, so that differential co-efficients, or the ratios of such infinitesimals, are definite numbers.

As Hegel's "notion" here again comes into conflict with all that is best established in abstract mathematical science, we must decline to follow Mr. Stirling through his generally incomprehensible vindications of Hegel. When Hegel's philosophy breaks down so sadly at the slightest touch of fact, can we waste our own time, or that of our readers, with endeavouring to attach a meaning to pages of this kind of *philosophy?*—

"The outside *Aarshauung* being viewed as the *con-*

tinuum, the *regula* may be regarded as the *discretum*; but it were a false conception, that of the continuum as made up of an infinite number of *discreta* (regulæ) infinitely small. Such continuum is but the *exemplification, proexumbration, externalisation* of the regula," &c. (p. 116.) W. S. J.

OUR BOOK SHELF

Junior Course of Practical Chemistry. By H. E. Roscoe, B.A., F.R.S., &c., and Francis Jones. (London: Macmillan and Co.)

THE work now before us represents the course of practical chemistry carried out by students entering the Owens College Laboratory. It commences with the preparation of the ordinary gases, which are, if anything, too shortly described; and then proceeds to the subject of blowpipe analysis and the preliminary examination of simple substances, and afterwards to the reactions of metals, &c., and qualitative analysis itself. The book does not deal in any way with theoretical chemistry, but the student is referred to Prof. Roscoe's "Lessons in Elementary Chemistry" for any explanation of this kind. This, of course, necessitates a considerable amount of extra reading, more particularly in the earlier portions of the book. The course of qualitative analysis, and so forth, through which the student has to pass, seems to be very similar to that which is now in use in most of our laboratories.

The various experiments, reactions, &c., are as a rule clearly described, but we notice one or two which would undoubtedly be better for some slight alteration and addition; thus, on p. 59, we find the following given as a method of testing for Baric sulphate:—"Barium sulphate fused with $Na_2\ Co_3$ and HCl added, yields $BaCl_2$ (flame coloration green), precipitated by $SrSo_4$ solution." Now we think that there is a strong probability that a student proceeding as directed in the book would again form the original Baric sulphate, and he would certainly not obtain any precipitate with Strontic sulphate solution, and probably would not obtain the green colouration. The same method is also given for the detection of Strontic sulphate. Another instance in which we think that clearness has perhaps been sacrificed to brevity is in Table A, but with a teacher at hand there need be little fear but that the student will easily overcome such minor difficulties. In fact the book is written with the desire to aid the teacher in his work, and not to dispense with his services altogether; in the former we think the book is very successful, but we do not believe that a student could well work through the book without such aid.

A number of well-selected questions is appended at the end of the book. They seem well adapted to test the student's knowledge of his work, and will in this way considerably lighten the teacher's labours.

We must also not forget to mention in terms of high praise the three short rules for the guidance of students, which are appended by Prof. Roscoe at the end of the preface, and we hope that every student who works by this volume will lay them to heart, and practise them with all sincerity.

The title of this book, "Junior Course," &c. scarcely conveyed to our minds exactly what we have found the book to be. It is more advanced than we anticipated, and yet, perhaps, it is not a thoroughly complete manual of qualitative analysis, although nearly so; but we must still thank the authors for a clear and succinct little manual, which will no doubt prove very useful to both teachers and students.

The Philosophy of Evolution. An Actonian Prize Essay. By B. T. Lowne. (Van Voorst.)

THE author of this short sketch of the theory of evolution is already favourably known by his treatise on the anatomy of the Blow-fly, a strictly anatomical work, abounding in detail, and not going beyond the region of fact. We can scarcely congratulate him, however, on the success of his theoretical attempts, as many of them are but weakly based, and others lead to very unreasonable deductions.

In the discussion of the variations which, according to the Darwinian hypothesis, give rise to the development of new forms, Mr. Lowne terms the greater tendency possessed, as he states, by some animals, to vary, plasticity, and the less tendency among others, rigidity; and he considers that these characters, plasticity and rigidity, are capable of being transmitted from generation to generation like other hereditary characters. At first sight this may appear highly probable, but to any one who considers the subject, it will be evident that it is based on an erroneous conception of the nature of that so frequently employed, but still ill-understood expression, variation. For the assumption of the existence of a struggle, together with the concomitant "Survival of the Fittest," means that the possible variation in a particular advantageous direction is tending to a limit, or in other words, that the continuation of the struggle is correlated with a tendency to the reduction to a minimum of the power to vary, for directly any advantageous tendency is developed, it is immediately run upon and exhausted.

The chapter on nutrition contains more than one proposition open to criticism; the function is incorrectly defined, and the ultimate destination of foods which is said to be in three directions, namely of nutrition, energy, and excretion, is very misleading. But it is in the explanation of the formation of the antlers of the Deer that a theory is given, which is not exceeded in rashness and lack of foundation by any lately put before the scientific world; the following is a sketch of the argument:—Herbivorous animals, specially ruminants, take into their system a superabundance of salines, the excess of which the kidney is not sufficiently developed to eliminate; consequently, on an axiom laid down by Sir J. Paget (who would be one of the first to object to this abuse of his words) that every part of the body may be looked upon as an excretion to every other part in highly complex organisms, this excess is got rid of by the development of the antlers, which contain a large amount of calcium salt, and are shed every year: the females have no horns, because in them the excess of salts is employed in the formation of the bones of their progeny. Such being the case, we do not know how Mr. Lowne explains the elimination of the salts in the Cavicorn ruminants, and their non-development in the males of all other herbivorous animals.

We cannot agree with our author in his attempt to derive all the higher forms of animal life from aquatic ancestors. Upon this supposition he attempts to prove that the Penguins and Auks belong to the early type of birds, and that they show marked reptilian affinities, but as they do nothing of the kind, his endeavour is worse than feeble. We are quite unable to see how the view "that the aquatic penguins belong to an early type of birds has been materially strengthened of late by Professor Marsh's remarkable discovery of an Ichthyornid type of birds in the Cretaceous shales of Kansas."

The elaborate markings of the flint shields of the Radiolaria and Diatomaceæ being somewhat like the curves which are produced on the surface of a vibrating metal plate, on which sand has been scattered, we are told that "nothing appears more probable than that similar points of vibration and rest exist upon the surface of these shield-forming organisms, and that the excreted silica which forms their shields comes to rest at the nodal points." This explanation is bold, to say the least, considering the very different circumstances under which the results are produced. Mr. Lowne should try to produce the curves or the vibrating metal plate under water.

Natural Theology being the subject for which this essay obtained a prize, some of its dogmas are shortly discussed. In answer to the statement that the hypothesis of a soul is objectionable "on the ground that it is not known to exist in nature, and cannot, therefore, be known to be capable of producing the effects ascribed to it," it is shown "that when the effects are such that they cannot be produced by any known cause, they must result from an unknown cause or causes capable of producing the effects ascribed to them." However, in an earlier part of the work it is remarked that Mr. Darwin has done injustice to his theory by comparing it to the undulatory theory of light, because the latter assumes the existence of an ether, which is an unknown agent. It is therefore to be inferred that the Darwinian hypothesis is on a better basis than that of the existence of a soul, from the perusal of an Actonian Prize essay!

Light Science for Leisure Hours. Second Series. Familiar Essays on Scientific Subjects, Natural Phenomena, &c., with a Sketch of the Life of Mary Somerville. By Richard A. Proctor, B.A. Camb., Honorary Secretary of the Royal Astronomical Society, author of "The Sun," "Other Worlds," "Saturn," "Essays on Astronomy," "The Orbs around Us," &c. (Longmans, 1873.)

THE essays in this volume have already appeared in various journals. Besides the life of Mrs. Somerville, the volume contains the following:—"The coming Transit of Venus, and British Preparations for observing it;" "The Ever-widening World of the Stars;" "Movements in the Star-depths;" "The great Nebula in Orion;" "The Sun's True Atmosphere;" "Something Wrong with the Sun;" an article occasioned by the intense heat of July last year; "News from Herschel's Planet;" "The two Comets of the Year 1868;" "Comets of Short Period;" "The Gulf Stream," "Oceanic Circulation," "Addendum in Reply to Dr. Carpenter;" "Climate of Great Britain;" "Low Barometer of the Antarctic Temperate Zone."

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Pay of Scientific Men

IT is unfortunately too true, as stated in your last week's leading article, that whether the claims of men of Science in serving their country are generally acknowledged in the future must to a large extent depend upon the men of Science themselves. I say unfortunately because, as a general rule, such claims, at least as far as pecuniary rewards go, could not be left in worse hands. I know so well how utterly repugnant it is to the feelings of all true and earnest workers in Science even to speak of such matters, however much they may be compelled to feel them sometimes, that they will be the last to force public attention to the question. Though this may be a natural and honourable feeling as far as each individual is concerned, I cannot help thinking that it is one which for the sake of the Science they love, it is a duty to place, for the time at least, in abeyance.

Very much has been said and written of late about the "Endowment of Scientific Research." I, for one, hold what you would probably consider rather heretical views on the subject, believing that the "protesters" against the report of the Committee on the Organisation of Academical Study, as well as the writer of your recent articles on the subject, are rather running the risk of losing a very substantial and comparatively easily attainable method of reaching the end we all have in view, whilst so keenly pursuing a very shadowy ideal. I think that Scientific Research can be endowed *indirectly*, so effectually and at comparatively so little trouble in overcoming old prejudices, and all the various obstacles to radical changes of organisation which I need not specify, that this should be the first object of all who have its promotion at heart. The far more difficult question of *direct* endowment will follow more appropriately and be carried out more efficiently when the body of educated scientific men in the country is larger than it is now, and the public generally, especially those in high places, have more appreciation of the claims of Science for its own sake.

The educated men of Science in this country are still but a handful; we want more, and there is but one way of obtaining them. Pay them better for their work, that it may be worth while for parents to allow their sons of promise to take up a scientific calling. What our Universities and to a certain extent our Government are now beginning to do to encourage scientific education, viz. offering prizes, scholarships, and even fellowships is a delusion and a snare, unless followed up by something more substantial.

There will never be wanting young minds ardent enough to commence the pursuit of Science for its own attractions, but it is positive cruelty to lure them on by bribes further in a path which will only lead them to the edge of a precipice or into a morass of hopeless difficulties. To be supported in a scientific pursuit when young, is of very doubtful advantage, if you are to find yourself landed in middle or old age, encompassed by all the stern realities of life and all the needs engendered by our complicated social system, with only the miserable and precarious pittance now accorded even to some of the most able veterans of Science. It is this which naturally and rightly discourages scientific research in this country; and it is this which could to a large extent be so easily remedied.

The urgent want is better paid appointments which can be held by men of high scientific attainments, more especially professorships at the Universities. I must confess that I am not one of those who think that a moderate amount of teaching work or even official duties of a scientific nature is any hindrance to a life of healthy and genuine advancement of Science by original research. On the contrary, they may be (if not overdone, as usually is the case in this country) rather an assistance; but that is a long question which I need not discuss on the present occasion.

As such appointments would probably only be given to those who had already shown evidence of their ability by their contributions to knowledge (and this will be more and more the case as the number of available candidates increases, and public opinion forms itself in such matters) the prospect of attaining one would be the greatest possible stimulus to scientific research in young men. Scholarships and Fellowships are valuable adjuncts to the training of such men, but nothing more. What I contend for is that if Science, as a profession, is to compete in its attraction with other callings, as law, medicine, the civil services, to say nothing of trade, we must provide far more liberally than at present for the endowment of the latter half of the lives of those that follow it. That a man should be able to grow wealthy by Science is not asked for, probably not to be desired. The advantages and pleasures of a life devoted to scientific pursuits are such that for myself (and probably most others would say the same) I would prefer them with a simple competency—by which I mean sufficient to join freely in intellectual society and to give one's children a good education—to the wealth of a millionaire acquired in any other way.

But in the present condition of things Science does not even do this, at least for the branches with which I am best acquainted. Some pursuits, such as chemistry, which bear more directly on the arts and commerce, stand on a different footing; but in biological Science I do not know of a position in the kingdom to which a man, however distinguished he may be in his subject, can aspire, in which he can live as I have described, unless aided by independent means.

To remedy this we want no new organisations; nothing, in act, but the simplest and most intelligible change in the present

state of things. In the first place the Government ought at once to increase the pay of all its scientific officers, such as the Astronomer Royal, the Director of Kew Gardens, and especially the Curators of the British Museum referred to in your article.

Secondly, the Universities, as bodies specially interested in the advancement of learning, and having (at least in the revenues of the Colleges) immense resources at their disposal which could legitimately be devoted to such purposes, ought to lose no time in largely increasing the number and the emoluments of their scientific professors, as has been so long and ably urged by the Rector of Lincoln College.

Lastly, certain still more strictly scientific bodies, who have in their own hands the appointment and pay of their fellow-workers, are especially concerned in showing their appreciation of their services, as it may fairly be taken as a standard by which the other cases may be judged. It is gratifying to find that in some of these bodies a liberal spirit is spontaneously showing itself, as in the case of the one with which I have the advantage of being associated. The Council of the Zoological Society is another example, although even here it takes time to shake off the narrow spirit of illiberality or economy which has so long prevailed in such matters. We think nothing (and very properly) of paying a judge or a bishop 5,000*l*. a year, but a fifth part of that sum for a first-class scientific man still seems to many a preposterous extravagance. There are many societies which, being mainly supported by scientific men themselves, are unfortunately without the means of doing justice to their officers, however much it might be their wish; but I cannot conclude without referring to one body which I think really might be expected to set a better example—a body composed solely of scientific men of the highest character, who have the nearly uncontrolled use of a large sum of public money to spend in carrying out a great scientific object; I mean the Meteorological Committee of the Royal Society. Whatever the committee may do personally in the way of suggestion and guidance, the real efficiency of the operations carried out under their care must depend upon the chief executive scientific officers. The committee, in fixing the proportion of the 10,000*l*. annually placed at their disposal by Parliament, which is devoted to the remuneration of these officers, afford, I am afraid, an illustration of what I stated in the beginning of this letter, that scientific men are not the best fitted to take care of their interests or those of their class. Eight hundred and four hundred a year respectively for the Land and Marine Superintendents of the departments, are considered by the committee as sufficient remuneration for such responsible posts. If a body of the first scientific men in the land think it is so, who can wonder that very unscientific Lords of the Treasury should be of the same mind. Doubtless it was with some fear of the same Lords in their eyes, that the committee fixed the lowest possible standard at which they thought they could get the work done. Happily for themselves and the country, they found competent *amateurs* willing to undertake it; but from such a body a different line of action might be expected; they should lead, not follow, the instincts of Chancellors of the Exchequer in such matters. If scientific men are reluctant to speak on such topics for themselves, the lovers of Science among men of influence, wealth, and position, are the more bound to speak for them.

July 21 W. H. FLOWER

Habits of Ants

SOME months ago (vol. vii. p. 443) I sent you an extract from a letter from Mr. Hague, a geologist residing in California, who gave me a very curious account of the terrifying effect on the other ants of the sight of a few which he had killed on one of their paths. Mr. Traherne Moggridge saw this account in NATURE, and wrote to me that he had heard from a gentleman who had lived in Australia that merely drawing a finger across the path deters ants from crossing the line.

Mr. Moggridge tried this experiment with some ants a Mentone with similar effects. I therefore sent the letter to Mr. Hague, and asked him to observe whether his ants were alarmed by the smell left by the finger, or were really terrified by the sight of their dead and dying comrades. The case appears curious, as I believe no one has ever observed an invertebrate animal realising danger by seeing the corpses of a fellow species. It is indeed very doubtful whether the higher animals can draw any such inferences from the sight; but I believe that everyone who has had experience in trapping animals is convinced that individuals who have never been caught learn that a trap is dangerous by seeing others caught.

Here follows Mr. Hague's letter, fully confirming his former statement. CHARLES DARWIN

"By a somewhat singular coincidence the first reappearance, since last winter, of any ants in the room where I then observed them occurred on the day when your last note arrived,—that is, after an interval of several months. Then a few were observed about the tumbler at the middle of the shelf and the vase at the other end from that whence they were first driven, although they all came from a hole near the base of the mantel, directly beneath the vase which they avoided.

"Acting on Mr. M's. suggestion, I first tried making simple finger marks on their path (the mantel is of marble) and found just the results which he describes in his note, as observed by himself at Mentone, that is, no marked symptoms of fear, but a dislike to the spot and an effort to avoid it by going around it, or by turning back and only crossing it again after an interval of time.

"I then killed several ants on the path, using a smooth stone or a piece of ivory, instead of my finger, to crush them. In this case the ants approaching all turned back as before and with much greater exhibition of fear than when the simple finger-marks was made. This I did repeatedly. The final result was the same as obtained last winter. They persisted in coming for a week or two, during which I continued to kill them, and then they disappeared and we have seen none since. It would appear from this that while the taint of the hand is sufficient to turn them back, the killing of their fellows, with a stone or other material, produces the effects described in my first note. This was made clear to me at that time from the behaviour of the ants the first day that I killed any, for on that occasion some of them approaching the vase from below, on reaching the upper edge of the mantel, peeped over and drew back on seeing what had happened about the vase, then turned away a little and after a moment tried again at another and another point along the edge with the same result in the end. Moreover, those that found themselves among the dead and dying, went from one writhing ant to another in great haste and excitement, exhibiting the signs of fright which I described.

"I hardly hope that any will return again, but if they do, and give me an opportunity, I shall endeavour to act further on Mr. M's. suggestion. "JAMES D. HAGUE"

San Francisco, June 26

Fertilisation of Viola tricolor and V. cornuta

ALLOW me to thank Mr. Kitchener for his correction of my spelling. What I object to in the word "be-pollen" is the harsh combination of syllables, which I should have thought would be offensive to any ears, whether scientific or not. The word "pollen," used as a verb, would be free from this fault, and would be objectionable chiefly from the possibility of confusion arising from the novelty of its use in this sense. Neither of these objections could apply to Mr. Kitchener's term "be-dust," but why coin a new word when a simpler one exists ready-made? Does not the ordinary English verb "to dust" equally give the exact meaning of *bestäuben?* I cannot, however, agree with Mr. Kitchener that it would be more expressive than "pollinate," as, unlike the Germans, we do not habitually use the word "dust" as a synonym for "pollen." I have no wish to dispute Mr. Bennett's conclusion that *Viola tricolor* is very commonly fertilised by "very minute insects of the Thrips kind," but only to

point out that in its whole structure the flower seems rather adapted for cross-impregnation by larger insects, and that at least some varieties are attractive to humble-bees. On this view, the opening between the two lower anthers, described by Mr. Kitchener, is necessary for the escape of the pollen, which falls, according to Hildebrand, without the help of insects, into the groove beneath, where it is held by the lining hairs until removed by insects. Besides humble-bees, I have seen the small cabbage butterfly (*Pieris rapæ*) sucking the flowers of a cultivated pansy.

With regard to *V. cornuta*, besides the absence of the black mark on the style, mentioned by Mr. Kitchener, which is not universally present in *V. tricolor*, it differs from the latter in the uniform size of the unvariegated, pale blue, or white flowers, the somewhat looser disposition of the petals, the great length of the spur, and the sweetness of the flowers at night, all characters leading to the belief that it is, in fact, a pansy (if I may use the word in a sub-generic sense), adapted to uniform conditions of life, and to fertilisation by *Noctuidæ*. A comparison of the present condition of two beds of this species in our garden, in connection with their surroundings, helps to strengthen this belief, of the practical truth of which I have been able to satisfy myself by the capture of *Cucullia umbratica* in the act of sucking the flowers. One of these beds, in an exposed part of the garden little frequented by moths (as I can testify from long experience), still displays a profusion of blossoms in all their virgin beauty, with only a few small capsules among them; in the other, in a sheltered nook, an old favourite "mothing-ground," the flowers are mostly past their prime, and a great number of well-filled capsules are already formed. By day I have seen the flowers visited by a few humble-bees, which seemed to have difficulty in reaching the nectar, and by the meadow-butterfly (*Hipparchia Janira*). Hosts of small flies run over the petals in bright sunshine, but rarely attempt to enter the nectary, and I have never seen such an attempt succeed. A remarkably long-beaked fly which I watched feeding on the pollen, as it repeatedly inserted and withdrew its proboscis, must probably have left some of the flower's own pollen on the stigma.

W. E. Hart

Kilderry, Co. Donegal, June 22

Spots on the Cherry-laurel

Can any of your readers tell me of what use to the plants are the small spots—glands I suppose—on the back of the laurel-leaf near the bottom of the rib? Sometimes there are two pairs, sometimes one; but no leaves seem to be without them. They are most apparent in the young leaves. They evidently contain something delectable to the bees, which frequent the laurels very much this year, and always fly to these spots upon the leaves; and the microscope shows a drop of liquid.

J. M. H.

Sidmouth

Your correspondent means, I suppose, the cherry-laurel. His observation is quite correct; such glands are to be found in similar situations on other leaves. I know of no explanation of their purpose or origin.

W. T. Thiselton Dyer

Turnham Green, July 10

Halomitra

There is a singular morphological coincidence between the specimen of *Orbitolites tenuissimus* Carpenter, figured on p. 91 of "The Depths of the Sea," and several specimens which I have seen of the corallum of a species of the *Fungia* group, genus *Halomitra* Dana. The *Orbitolites* has the appearance of having been developed on a nucleus formed by a frustum of a former specimen. The outer rings are altogether unconformable with those of the truncated segment composing the nucleus; and it is somewhat interesting to notice, as illustrated by the figure in Prof. Wyville Thomson's work, how the growth of the Foraminifer, oppressed at the corners and advancing *per saltum* at the excavated sides, has shaped itself towards the completion of its normal disc-like form.

An appearance precisely similar has come under my notice in the corallum of *Halomitra*. Two specimens in the Free Public Museum, Liverpool, from the Solomon Islands, exhibit this peculiarity, and of about eight or ten other specimens seen by myself, I cannot recollect more than one in which the large frustum of a former corallum, constituting an unconformable nucleus, did not distinctly appear.

In a single case the presumption would be altogether in favour of attributing the peculiarity to an accidental fracture of a former corallum; but its frequent occurrence suggests that it may be worth while to inquire into the possibility of spontaneous fission taking place in the adult *Halomitra*. Some of the *Fungidæ* are said to possess powers of limited locomotion. It is quite conceivable that a great extension of size in the coral might interfere with its mobility and render division advantageous. That the Zoantharian Actinozoa are able to re-absorb solid portions of their coralla is variously illustrated, no example being more familiar than that of the young of several species of *Fungia*, which are attached to the under side of the parent polype by a strong neck of cœnenchyme, which is subsequently absorbed and the young are liberated.

Henry H. Higgins

Periodicity of Rainfall

I have observed in recent numbers of Nature a discussion upon the subject of the Periodicity of Rainfall, and its connection with sun-spots, and I hoped by an examination of the Rainfall Returns of this island (Barbados), which I have collected for 30 years, 1843 to 1872, to have been able to confirm the theory broached by Mr. Meldrum and Mr. N. Lockyer, which is so interesting in itself, and might lead to such important results. But assuming that sun-spots affect all parts of the globe equally, and that periodicity prevails in all alike, the experience of Barbados is opposed to the theory, and I am led to the conclusion that it was "chance alone" that led to the coincidences noticed by Mr. Symons in his letter published in vol. viii. p. 143.

In the following calculation I state the years separately in order to show that not only the triennial and quinquennial averages, but the individual years, contradict the theory. I am able to furnish six periods—three of maximum and three of minimum sun-spots. Of the triennial averages two of each show an absolute equality; in the third the rainfall is in an *opposite* proportion to the sun-spots. The quinquennial averages do not materially disturb those results. As regards individual years, the rainfall was much above the average in two of the minimum sun-spot years; and was above it only in one of the maximum sun-spot years; in the second it was an average; in the third it was excessively below it. The average of the island for 25 years, from 1847 to 1871, is 57·74 inches, based upon the mean of 3 stations in 1843, and increasing to 141 in 1871.

		Yearly Rainfall.	Average of 3 years.	Average of 5 years.
	43	45·31		
Minimum	1844	74·45	54·56	
	45	43·91		
	46	65·82		
	47	48·10		
Maximum	1848	63·77	54·86	59·67
	49	52·77		
	50	67·88		
	54	50·88		
	55	77·31		
Minimum	1856	48·49	62·23	56·56
	57	60·90		
	58	45·22		
	58	45·22		
	59	56·22		
Maximum	1860	57·91	61·98	58·09
	61	73·82		
	62	59·27		
	65	68·64		
	66	59·68		
Minimum	1867	69·93	58·07	58·27
	68	44·60		
	69	48·52		
	69	48·52		
	70	60·17		
Maximum	1871	41·46	50·00	52·71
	72	48·39		
	73	65·00		

I have ventured to estimate the rainfall of the present year with much confidence upon the data given in the accompanying notice, with which I need not trouble your readers.

Rawson W. Rawson

NOTES FROM THE "CHALLENGER"

IV.

ON Saturday, the 15th of March, before going into the harbour of St. Thomas, a sounding was taken in 450 fathoms off the island of Sombrero. The bottom brought up by the sounding machine was globigerina mud largely mixed with broken shells, chiefly those of pteropods. The dredge was put over early, and veered to 1000 fathoms. At noon it was hauled up half filled with calcareous ooze. It was again sent down, and brought up early in the afternoon with a like freight. These dredgings, which we did not regard as entering into the regular work of the sections, but which were only undertaken to give us a general idea of the deep-water fauna of the West Indian province, may be taken in connection with one or two hauls taken with the same object and under the same circumstances, in waters of nearly equal depth on the 25th of March, after leaving St Thomas. The careful examination of this zone, between 300 and 1,200 fathoms among the West Indian Islands, will undoubtedly add enormously to zoological knowledge. The objects of the present expedition do not, of course, include a detailed investigation of this kind, which must be done quietly in a small steamer, by some one on the spot, and will require the patient work of several years. Even the few hauls of the dredge which we had it in our power to make, brought to light a number of new and highly interesting forms, representing nearly all the invertebrate groups. A thorough investigation of the belt must yield a wonderful harvest.

Fig. 1.—Astacus Zaleucus, v. W.-S.

In those dredgings on the 15th we got several sponges belonging to the Hexactinellidæ, very closely allied to those which we had previously met with in moderately deep water off the coast of Portugal, showing that the distribution of this remarkable order in deep water is very wide. Several stony corals occurred, but of all these, with the exception of a species of *Stylaster*, which was very abundant at this station, we got better examples on a subsequent occasion. The *Stylaster* agrees very closely with the description and figure given by Pourtalés of *S. complanatus*. The only marked difference is that the primary and secondary septa do not unite to the same extent as shown in the figure.

Fig. 2.—Salenica Varispina, A Ag.

In this dredging two very interesting crustaceans occurred, both belonging to the decapod family Astacidæ,

and both participating in a singular deficiency, the total absence of eyes. One of these has been referred by Dr. v. Willemoes-Suhm to his genus Deidamia. It agrees with the species described in my former report in all its leading characters, although certain marked differences must lead to a slight modification of the characters of the genus as formerly defined. In *Deidamia leptodactyla* all the five pairs of ambulatory legs bear chelæ, while it is a character of the typical Astacidæ that chelæ are present on three pairs only. In the new species there are chelæ on four pairs of the ambulatory legs, the fifth pair ending in simple curved claws. The two species agree with one another, and with *Astacus*, in possessing a lamellar appendage at the base of the outer antennæ, and with this they have the flattened carapace of *Palinurus*. These characters have not been hitherto observed in combination, and their so occurring seems to be a more valuable generic character than the variable one of the form of the limbs. The character of this genus will now stand thus :—

Deidamia.—Cephalothorax flattened, with a compressed free lateral margin. A lamellar appendage at

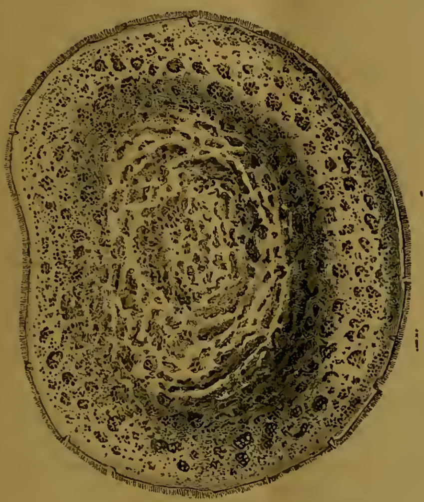

FIG. 3.—Hyalonema Toxeres, Wyville Thomson (Upper surface of sponge body).

base of each of the outer antennæ. Swimmerets, consisting of three joints with two palpi. No trace of eyes or of eyestalks.

D. leptodactyla v. W.-S.—All the ambulatory feet bearing chelæ.

D. crucifer v. W.-S.—Four pairs of the ambulatory feet bearing chelæ.

As in *D. leptodactyla,* not only are the eyes and eyestalks absent, but there is no indication of a space for their accommodation in the position in which eyes are normally developed.

Deidamia crucifer certainly differs widely in general appearance from the recent Astacidæ, at the end of which family we should, however, be inclined to place it for the present. It has a very close resemblance to some fossil forms, particularly the varying species of the genus *Eryon.* It has been already remarked that *Deidamia,* in its flattened cephalothorax, approaches the Palinuridæ; in all the living members of that family, however, the first pair of legs are monodactylous, while in *Deidamia* they are didactylous. The fossil genus *Eryon* forms an exception in this particular among Palinurids, with which it has hitherto been arranged, and has the first pair of limbs didactylous, as in *Deidamia.* It has not yet been ascertained whether *Eryon* has a lamellar appendage at the base of the outer antennæ. If this appendage be absent, there is probably scarcely sufficient ground for separating *Deidamia* generically from *Eryon.* It is very likely that when the recent deep-sea forms near the Astacidæ and Palinuridæ come to be carefully correlated with the cretaceous and Jurassic species, it may be necessary to establish an additional family.

The second crustacean, although having little of the facies of the typical *Astaci,* presents apparently no characters of sufficient value to warrant its separation from that genus.

Astacus zaleucus, v. W.-S. (Fig. 2), with its long compressed cephalothorax, flattened abdomen and unequal chelæ, has at first sight somewhat the appearance of a *Callianassa.*

The total length of the animal is 120 mm.; the cephalothorax, 50, and the abdomen, [60 mm. The

FIG. 4.—Hyalonema (Lower surface).

carapace is hard, and firm, though only slightly calcified. It is greatly compressed laterally, rising into a high arch. It terminates in front in a slender spiny rostrum, 8 mm. in length. The rostrum is covered with a thick felting of hair, which extends backwards, forming two hairy triangles on the anterior part of the cephalothorax In front of the carapace, between its anterior and upper edge and the insertions of the antennæ, in the position of the eyes in such forms as *Astacus fluviatilis,* there are two round vacant spaces which look as if the eyestalks and eyes had been carefully extirpated and the space they occupied closed with a chitinous membrane. The lamellar appendage of the outer antennæ has teeth along its inner border. It extends to the middle of the second basal segment of the antenna, which is remarkably long. The flagella of the outer antennæ are 130 mm. in length. The inner antennæ originate in a line with the outer. The funiculus is shorter, and the flagella, which are equal in length, are much shorter than those of the outer antennæ.

The parts of the mouth are normal. The three first pairs of ambulatory legs are terminated by chelæ, the fourth pair bear recurved claws, and the fifth abortive stump-like claws. The chelæ of the first pair of legs are strangely developed, particularly the right chelæ, which is double the length of the left, and with its formidable ranges of long spines along the inner border of each claw reproduces on a small scale the jaws of the Gangetic gavial. The last segment of the pereion is not covered by the carapace but is in moveable connection with it. The first segment of the abdomen is very small, and the segments gradually increase up to the fourth, which the fifth and sixth equal in size. The abdominal segments are flattened from above downwards. The telson is quadrate, and combines with the two pairs of caudal appendages, which are widely expanded laterally to form the caudal fin. The dorsal surfaces of the second, third, and fourth abdominal segments, and the margin of the tail, are thickly covered with woolly hair. The individual being a male, the first pair of swimmerets consist of long slender appendages, and the four succeeding pairs have one strong, round, basal joint, to which are attached two palpi fringed with hair. There is some resemblance between this form and *Calianassa*, but in this genus the lamellar appendage to the outer antenna is absent. There are four pairs of limbs with chelæ instead of three, and the carapace is soft.

To the genus *Astacus*, therefore, with which it has all characters in common except the great development of the right chela and the total absence of eyes—neither characters of generic value—the present species must be referred.

A. Zaleucus, n. sp. (Fig. 1).

Rostrum spiny, elongated. Lamellar appendage of the outer antennæ reaching to the middle of the second joint of the funiculus. Chelæ on three pairs of ambulatory feet, those on the first pair strongly but unequally developed. Cephalothorax very much compressed laterally, eyestalks and eyes entirely wanting.

On Sunday, March 16, we anchored in the Gregaria Channel, at the entrance of the harbour of Charlotte Amalia. We spent a few very pleasant days at St. Thomas, some of the civilians of our party enjoying greatly their first experience of life and scenery within the tropics. M. Gardé, the Danish Governor, received us with the most friendly hospitality. He is a naval man, and was greatly interested in our investigations, and his Aide-de-Camp, Baron Eggers, had collected and worked out the plants of the Island with care, and was otherwise well acquainted with its natural history.

The natural history of the island of St. Thomas is tolerably well known, and large collections of its fauna and flora have been sent home from time to time by very competent naturalists to the Museum at Copenhagen. On the present occasion our time was much too limited to attempt to make collections, so the naturalists contented themselves with a little shallow water dredging, and such a general survey of the island and shores as might familiarise them with the more characteristic forms of animal and vegetable life; for while the Atlantic Islands Madeira, and the Canaries, although gradually assuming a more tropical character, maintain the most intimate relations in natural products with the south of Europe, in Tropical America everything is changed, and it takes a little time to become familiar with new acquaintances whom one has hitherto known, if he has known them at all, only from descriptions or figures, or at best mummied or pickled, or otherwise in inadequate effigy. Ophiurideas are particularly plentiful at St. Thomas, and we made large collections of these, particularly of the many large and characteristic West Indian species of the genus *Ophioderma*.

On the 24th of March we left the harbour of Charlotte Amalia and proceeded with a light north-easterly breeze towards the Culebra passage. The next morning we sounded in 625 fathoms. The ooze was closer and more free from shells and coral than in the former haul, but otherwise much of the same character. This time the dredge came up about half full, and on sifting its contents many interesting additions were made to our collections. Here we met for the first time with the curious little crinoid, *Rhizocrinus lofotensis*, for which we had been on the outlook since the beginning of the cruise, and *Salenia varispina*, which we now recognise as a very widely distributed inhabitant of the deeper water.

This elegant little urchin (Fig. 2) is about 10 mm. in diameter of the test. It resembles in general appearance young specimens of *Cidaris hystrix*. The ambulacral zones are narrow, the interambulacral correspondingly wide, and both are furnished with double rows of flat, paddle-shaped, secondary spines beautifully striated in purple and white, ranged along the middle line, from which they shed outwards on either side. The primary tubercles are large, imperforate, and distinctly crenated. Some of the larger of the primary spines are 50 mm. in length, ·8 mm. in diameter, and cylindrical, gradually tapering towards the point. They are fluted and serrated along the ridges with sharp prickles. The spines in all the specimens we have dredged are very uniform; some are slightly curved, but they scarcely agree with the description given by Prof. A. Agassiz, from a young specimen, of being "of all shapes." The spines round the mouth are short, some of them slightly, flattened and sharply denticulated.

The corals which were abundant in individuals were all deep-water forms. They have been examined by Mr. Moseley, who refers the majority to species which have been described by M. de Pourtalès * from the Straits of Florida.

Two examples of the sponge-body of a very handsome Hyalonema were sifted out of the coral mud. Unfortunately in both cases the sponge had been torn from the central coil, and the absence of the coil might have thrown some little doubt upon the form and mode of finish of the complete animal, so that it was extremely fortunate that a young specimen of the same species about 40 mm. in length was caught in the tangles quite perfect.

Hyalonema toxeres, new species, resembles closely the other known species *H. lusitanicum* and *H. sieboldi* in general appearance and in the arrangement of its parts. A more or less funnel-shaped sponge presents two surfaces covered with a network of different patterns formed by varying arrangements of large fine rayed spicules. The upper concave surface shows a number of oscular openings irregularly arranged, and the lower surface a more uniform network of pores, some of which seem to be inhalent and others exhalent.

The central axis of the sponge is closely warped into the upper part of a coil of long and strong glassy spicules which, as in the other species, serve to anchor the sponge in the soft mud. Both of the species dredged have the sponge more flattened and expanded than it is in *H. lusitanicum*. In one of them it is nearly flat (Fig. 3), forming a reniform cake-like expansion 80 mm. in length by 70 mm. in width, and about 8 mm. in thickness. The upper or oscular surface is covered by an exceedingly close network with groups of large openings at nearly equal intervals. It is slightly raised in the centre. The central elevation is followed by a slight depression, and the upper wall then passes out nearly horizontally to a sharp peripheral edge fringed with long delicate spicules, each consisting of a slender central shaft with a cross of four short transverse processes in the centre. The outer half of the central axis is delicately feathered. The lower surface of the sponge (Fig. 4) is protected by a singularly

* Illustrated Catalogue of the Museum of Comparative Zoology at Harvard College, No. 4—Deep-sea Corals. By L. F. de Pourtalès, Cambridge (Mass.), 1871.

elegant net-work of sarcode with wide oval and round meshes radiating irregularly from a central point. The membrane is traversed by irregularly radiating ridges of firmer substance, which unite in the centre in a projecting boss at the point where, in this specimen, the "glass-rope" has unfortunately been torn out.

WYVILLE THOMSON

(*To be continued.*)

THE ANCESTRY OF INSECTS

WITHIN a very few days after my last article on the "Origin and Metamorphoses of Insects" appeared in NATURE, I received from Mr. Packard a memoir,* under the above title, in which he developes his latest views on the same subject; and I am happy to find that his views do not differ so much from mine as I had supposed. He lays great stress, as is natural, on the larval forms. "If we compare," he says, "these early stages of mites and myriopods, and those of the true six-footed insects, as in the larval Meloë, Cicada, Thrips, and Dragon-fly, we shall see quite plainly that they all share a common form. What does this mean? To the systematist who concerns himself with the classification of the myriads of different insects now living, it is a relief to find that all can be reduced to the comparatively simple forms sketched above. It is to him a proof of the unity of organisation pervading the world of insects. He sees how Nature, seizing upon this archetypal form has, by simple modifications of parts here and there, by the addition of wings and other organs wanting in these simple creatures, rung numberless changes in this elemental form." And again (p. 151), "Going back to the larval period, and studying the insect in the egg, we find that nearly all the insects yet observed agree most strikingly in their mode of growth, so that, for instance, the earlier stages of the germ of a bee, fly, or beetle, bear a remarkable resemblance to each other, and suggest again, more forcibly than when we examine the larval condition, that a common design or pattern pervades all."

He distinguishes, as in his previous writings (p. 175), two principal types of larvæ:—

"There are two forms of insectean larvæ which are pretty constant. One we call leptiform, from its general resemblance to the larvæ of the mites (Leptus). The larvæ of all the Neuroptera, except those of the Phryganeidæ and Panorpidæ (which are cylindrical, and resemble caterpillars), are more or less leptiform, *i.e.*, have a flattened or oval body, with long thoracic legs. Such are the larvæ of the Orthoptera and Hemiptera, and the Coleoptera (except the Curculionidæ; possibly the Cerambycidæ and Buprestidæ, which approach the maggot-like form of the larvæ of weevils). On the other hand, taking the caterpillar or bee larvæ, with their cylindrical fleshy bodies, in most respects typical of larval forms of the Hymenoptera, Lepidoptera, and Diptera, as the type of the eruciform larva," &c.

At first sight it would appear that Mr. Packard's conclusions differ widely from those which I have advocated. He rejects, indeed, the suggestion made by Haeckel that the "common stem form of all Tracheata" may be found in "Zoeaform Crustacea." It is evident, he says (p. 159), that "the Leptus fundamentally differs from the Nauplius and begins life on a higher plane. We reject, therefore, the crustacean origin of the insects." And elsewhere "we find through the researches of Messrs. Hartt and Scudder that there were highly-developed insects, such as may-flies, grasshoppers, &c., in the Devonian rocks of New Brunswick, leading us to expect the discovery of low insects even in the Upper Silurian rocks. At any rate this discovery pushes back the origin of insects beyond a time when there were true Zoëæ, as the shrimps and other allies are not actually known to exist so far back as the Silurian, not having as yet been found below the coal-measures."

But then he observes that the "larvæ of the earliest insects were probably leptiform, and the eruciform condition is consequently an acquired one, as suggested by Fritz Mülller." Again, "for reasons which we will not pause here to discuss, we have always regarded the eruciform type of larva as the highest. That it is the result of degradation from the Leptus or Campodea form, we should be unwilling to admit." And once more, "The Caterpillar is a later production than the young, wingless Cockroach."

Mr. Packard had already expressed these opinions elsewhere, and as I have on the contrary suggested that the grublike, or Lindia-forms were the first to come into existence, then the Tardigrade-form, and lastly, the Campodea-form, I had supposed that our views were in direct opposition to one another: but I am glad to find from other passages that after all there is not so much dfference as these passages would seem to indicate. I cannot, indeed, agree with him in his classification of Insect larvæ; he ranks the Caterpillars with the grubs and maggots of Bees and Flies, as a class for which he proposes the term "eruciform" in opposition to the "leptiform" larvæ of Orthoptera, Hemiptera, and most Coleoptera. It seems to me, on the contrary, that the two great groups are the Hexapod or Campodea-form, and the apod, grublike type, which I have proposed to call the Lindia-form. At the first glance, no doubt, the heavy sluggish Caterpillar seems to have more in common with the grub of a Bee than with the active larvæ of Coleoptera. The difference, however, is one of habit, not of type.

As regards the ancestral forms of Insects, Mr. Packard considers that "while the Poduras (p. 154) may be said to form a specialised type, the Bristle-tails (*Lepisma*, *Machilis*, *Nicolitea*, and *Campodea*) are, as we have seen, much more highly organised, and form a generalised or comprehensive type. They resemble, in their general form, the larvæ of Ephemerids, and perhaps more closely the immature Perla, and also the wingless Cockroaches. Now such forms as these Thysanura, together with the mites and singular Pauropus, we cannot avoid suspecting to have been among the earliest to appear upon the earth; and putting together the facts, first, of their low organisation, secondly, of their comprehensive structure, resembling the larvæ of other insects, and thirdly, of their probable great antiquity, we naturally look to them as being related in form to what we may conceive to have been the ancestor of the class of insects. Not that the animals mentioned above were the actual ancestors, but that certain insects bearing a greater resemblance to them than any others with which we are acquainted, and belonging possibly to families and orders now extinct were the prototypes and progenitors of the insects now known."

As regards the probable origin of this Leptus form, Mr. Packard's views are expressed in the following passage (p. 169):—"While the Crustacea may have resulted from a series of prototypes leading up from the Rotifers, it is barely possible that one of these creatures may have given rise to a form resulting in two series of beings, one leading to the Leptus form, the other to the Nauplius. For the true Annelides (Chætopods) are too circumscribed and homogeneous a group to allow us to look to them for the ancestral forms of insects. But that the insects may have descended from some low worms is not improbable, when we reflect that the Syllis and allied genera of Annelides bear appendages consisting of numerous joints; indeed, the strange *Dujardinia rotifera*, figured by Quatrefages, in its general form is remarkably like the larva of Chloëon."

Moreover, though Mr. Packard says that "the caterpillar is a later production than the young wingless, cockroach," he elsewhere (p. 182) says, "it is evident that in the

* Being a chapter from "Our Common Insects," by A. S. Packard, jun. (Printed in advance.)

young grasshoppers the metamorphoses have been passed through, so to speak, in the egg, while the bee larva is almost embryonic in its build." Mr. Packard admits then that theoretically the Orthoptera do pass through transformations similar to those of metamorphic insects; though, while bees are hatched in an early larval, "almost embyonic" condition, Orthoptera pass through these early stages rapidly, and within the egg.

Mr. Packard then derives the various groups of Insecta as I do from ancestors more or less resembling the hexapod larvæ of Neuroptera, &c.; these from a more acariform type; and these again from lower, more vermiform ancestors.

That the Lindia-type larvæ *of Diptera* are of more recent origin than the Campodea-form larvæ of Neuroptera of course I admit, because the palæontological evidence seems to show that the Neuroptera are a more ancient group than the Diptera; but I am not the less of opinion that the Lindia type itself is more ancient than the Neuropterous.

How far the form of any given existing larva is adaptive and how far it is hereditary, is a comparatively minor, though interesting question, and I am glad to find that there is less difference of opinion than I had supposed between Mr. Packard and myself as to the various stages through which in the long lapse of geological ages the existing types of insects have gradually been evolved.

JOHN LUBBOCK

*NOTES ON THE HONEY-MAKING ANT OF TEXAS AND NEW MEXICO**

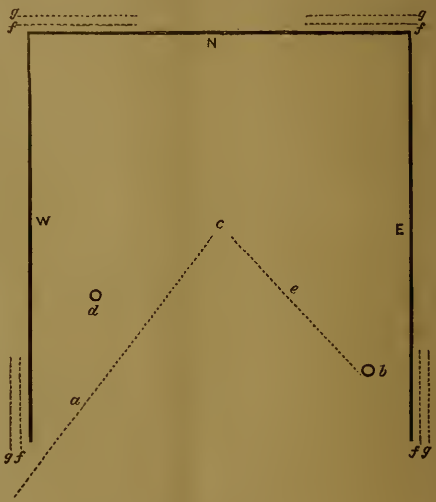
THE natural history of this very curious species (*Myrmecocystus mexicanus* Westwood) is so little known, that the preservation of every fact connected with its economy becomes a matter of considerable scientific importance, and the following observations, gleaned from Capt. W. B. Fleeson of this city, who has recently had an opportunity of studying the ants in their native haunts, may, it is hoped, be not without interest.

The community appears to consist of three distinct kinds of ants, probably of two separate genera, whose offices in the general order of the nest would seem to be entirely apart from each other, and who perform the labour allotted to them without the least encroachment upon the duties of their fellows. The larger number of individuals consist of yellow worker ants of two kinds, one of which, of a pale golden yellow colour, about one-third of an inch in length, acts as nurses and feeders of the honey-making kind, who do not quit the interior of the nest, "their sole purpose being, apparently, to elaborate a kind of honey, which they are said to discharge into prepared receptacles, and which constitutes the food of the entire population. In these honey-seeking workers the abdomen is distended into a large, globose, bladder-like form, about the size of a pea." The third variety of ant is much larger, black in colour, and with very formidable mandibles. For the purpose of better understanding the doings of this strange community, we will designate them as follows:—

No. 1.—Yellow workers; nurse and feeders.
No. 2.—Yellow workers; honey-makers.
No. 3.—Black workers; guards and purveyors.

The site chosen for the nest is usually some sandy soil in the neighbourhood of shrubs and flowers, and the space occupied is about from four to five feet square. Unlike the nests of most other ants, however, the surface of the soil is usually undisturbed, and but for the presence of the insects themselves, presents a very different appearance from the ordinary communities, the ground having been subjected to no disturbance, and not pulverised and rendered loose as is the case with the majority of species.

The black workers (No. 3) surround the nest as guard or sentinels, and are always in a state of great activity. They form two lines of defence, moving different ways, their march always being along three sides of a square, one column moving from the south-east to the south-west corners of the fortification, while the other proceeds in the opposite direction. In most of the nests examined by Captain Fleeson, the direction of the nest was usually towards the north; the east, west and northern sides being surrounded by the soldiers, while the southern portion was left open and undefended. In case of any enemy approaching the encampment, a number of the guards leave their station in the line and sally forth to face the intruder, raising themselves upon their hind tarsi, and moving their somewhat formidable mandibles to and fro as if in defiance of their foe. Spiders, wasps, beetles, and other insects are, if they come too near to the hive attacked by them in the most merciless manner, and the dead body of the vanquished is speedily removed from the neighbourhood of the nest, the conquerors marching back to resume their places in the line of defence, their



object in the destruction of other insects being the protection of their encampment, and not the obtaining of food. While one section of the black workers is thus engaged as sentinels, another and still more numerous division will be found busily employed in entering the quadrangle by a diagonal line bearing north-east, and carrying in their mouths flowers and fragments of aromatic leaves which they deposit in the centre of the square. A reference to the accompanying sketch will give a more clear understanding of their course; the dotted line *a* representing the path of this latter section, while the mound of flowers and leaves is marked *c*. If the line *a* be followed in a south-west direction, it will be found to lead to the trees and shrubs upon which another division of the black workers is settled, engaged in biting off the petals and leaves to be collected and conveyed to the nest by their assistants below. On the west side of the encampment is a hole marked *d* leading down to the interior of the nest, which is probably chiefly intended for the introduction of air, as in case of any individuals carrying their loads into it, they imme-

* By Henry Edwards, Californian Academy of Sciences. Communicated by Mr. Charles Darwin, F.R.S.

diately emerge and bear them to the common heap, as if conscious of having been guilty of an error. A smaller hole near to the south-east corner of the square, is the only other means by which the interior can be reached, and down this aperture, marked *b*, the flowers gathered by the black workers are carried along the line *e*, from the heap in the centre of the square, by a number of smaller yellow workers (No. 1), who, with their weaker frames and less developed mouth organs, seem adapted for the gentler office of nurses for the colony within. It is remarkable that no black ant is ever seen upon the line *e*, and no yellow one ever approaches the line *a*, each keeping his own separate station and following his given line of duty with a steadfastness which is as wonderful as it is admirable. By removing the soil to a depth of about three feet, and tracing the course of the galleries from the entrance (*b*) and (*d*), a small excavation is reached, across which is spread in the form of a spider's web, a net work of squares spun by the insects, the squares being about one-quarter inch across, and the ends of the web fastened firmly to the earth of the sides of the hollow space which forms the bottom of the excavation. In each one of the squares, supported by the web, sits one of the honey-making workers (No. 2), apparently in the condition of a prisoner, as it does not appear that these creatures ever quit the nest. Indeed it would be difficult for them to do so, as their abdomens are so swollen out by the honey which they contain, as to render locomotion a task of difficulty, if not to make it utterly impossible.

The workers (No. 1), provide them with a constant supply of flowers and pollen, which, by a process analogous to that of the bee, they convert into honey. The fact that the remainder of the inhabitants feed on the supply thus obtained, though it is surmised, has not been established by actual observation; indeed with reference to many of the habits of these creatures, we are at present left in total ignorance, it being a reasonable supposition that, in insects so remarkable in many of their habits, other interesting facts are yet to be brought to light respecting them. It would be of great value to learn the specific rank of the black workers (No. 3), and to know the sexes of the species forming the community, their season and manner of pairing, and whether the honey-makers are themselves used as food, or if they excrete their saccharine fluid for the benefit of the inhabitants in general, and then proceed to distil more. I regret that at this time I am only able to bring before the notice of the Academy, specimens of the honey-makers (No. 2), the other members of the community, except from Captain Fleeson's description, being quite unknown to me. It is, however, my hope that at a future meeting I may be enabled to exhibit the other varieties, and to give some more extended information upon this very interesting subject. The honey is much sought after by the Mexicans, who not only use it as a delicate article of food, but apply it to bruised and swollen limbs, ascribing to it great healing properties. The species is said to be very abundant in the neighbourhood of Santa Fé, New Mexico, in which district the observations of Capt. Fleeson were made.

NOTES

THE arrangements for the forty-third meeting of the British Association at Bradford, have been pretty nearly completed. The General Committee will meet on September 17, the opening day, at 1 P.M., for the election of sectional officers, and the despatch of business usually brought before that body. The concluding meeting takes place on September 24. We regret very much to hear that Mr. Joule, on account of ill-health, has been compelled to resign the presidency; Prof. W. A. Williamson, will, it is said, be appointed in his place.

THE forty-sixth meeting of the German Association of Naturalists and Physicians will be held this year at Wiesbaden from September 18 to 24. Communications are to be addressed to Drs. Fresenius and Haas Senior.

WE are glad to see so influential a paper as the *Times* give so prominent a place to a notice of Sir Charles Wheatstone's election to the French Academy, which we ourselves noted a fortnight ago. There is no doubt that if we take into consideration the amount and value of the services Sir Charles has rendered to Science, both in its theoretical and practical aspects, he must be ranked as among the most eminent men of the time. The following is the notice in the *Times*:—

"Sir Charles Wheatstone was elected, on the 30th ult., Foreig Associate of the French Academy of Sciences, to fill the vacancy occasioned by the death of Baron Liebig. He was for many years previously corresponding member of the Academy; but the honour recently conferred upon him is the highest which it is in the power of that body to confer upon a foreigner. The election was nearly unanimous, as he obtained 43 out of 45 votes. Sir Charles has also lately received from the French Society for the Encouragement of National Industry the great medal of Ampère, which is awarded every six years for what is considered the most important application of Science to Industry. The former recipients of this medal were Henri Sainte-Claire Deville, who introduced the manufacture of aluminum; De Lesseps, the Engineer of the Suez Canal; and Boussingault, distinguished for his researches in agriculture.

GUSTAV ROSE, the celebrated mineralogist, died after a few days' illness on the 15th inst., in the 75th year of his age and the 50th of his connection with the University of Berlin. His mind and power of work remained unimpaired almost to the last, and he was able on his sick bed to dictate to his son the results of his last researches.

MR. J. S. DAVENPORT was elected on Wednesday, the 16th inst., Assistant-Secretary to the Royal Horticultural Society, in the place of Mr. Richards, who has accepted a post under the Commissioners of the International Exhibition.

THE Chair of Physiology at Edinburgh is likely to be soon vacant, we believe, by the resignation of Prof. Hughes Bennet, from ill health. There are several likely candidates for the prospective vacancy, all of them good men:—Dr. McKendrick, who has for some time efficiently discharged the duties of the chair, and a paper by whom in conjunction with Mr. James Dewar, on the Physiological Action of Light, we published a fortnight ago; Prof. Rutherford, a former assistant of Prof. Bennet's, and Dr. J. Bell Pettigrew, F.R.S., who has distinguished himself as an investigator in comparative anatomy. There is a rumour that Prof. Burdon Sanderson is also a candidate.

WE regret very much to hear that Mr. Saville Kent has resigned his position in connection with the Brighton Aquarium. We do not desire to express any opinion upon the misunderstanding which has resulted in Mr. Kent's resignation, but we cannot help saying that we consider it a great loss to Science that the Aquarium is now without a resident naturalist. The Brighton Aquarium offers unequalled opportunities for studying the habits of fishes, and during Mr. Kent's short connection with the establishment he has considerably increased our knowledge of this department of Natural History, and we confidently looked to the Aquarium to add still more to scientific knowledge in this direction. It would be a grievous thing, indeed, if the Directors should allow their fine establishment to degenerate into a mere place of popular amusement.

MR. GEORGE SMITH returned on Saturday last from his successful labours in Assyria.

THE number of institutions in America devoted to education of all kinds and of all grades, endowed and supported both by the State and by the generosity of private individuals, theoretically and practically open to all-comers, is almost sufficient to fill a Briton with envy and chagrin, when he contrasts it with the comparative meagreness of the educational means of his own country, hampered with so many traditional restrictions. One of the most admirable, best organised, and most successful of these American institutions is the Sheffield Scientific School of Yale College, the Eighth Annual Report of which for 1872–73 we have just received. The School forms the Scientific Faculty of Yale College, on the same footing as the other faculties of Arts, Medicine, Law, and Divinity, and, to judge from the Report, must be one of the most successful and efficient scientific schools in the world. It owes its name to Mr. Joseph E. Sheffield, who, in 1860, presented it with a magnificent building and a liberal endowment, and has since frequently munificently increased his original gifts, his last one being an additional building of five stories, with ample accommodation, which was very much needed to meet the rapid increase in the number of students, which, during the last session, was 201. The education supplied is in all branches of Science, students being at liberty to choose a course of instruction to fit them for pure scientific research, or for some practical application of scientific principles, as engineering, agriculture, &c. The school is most liberally supplied with scientific apparatus in all departments, seems to have plenty of funds at its command, furnished both by the State and by private individuals, and, to judge from the prospectus, provides students with a thoroughly well-organised and complete course of scientific instruction in each of its numerous departments. "The benefit," the report says, "which the Scientific School has conferred upon the State in turning out young men who, on leaving the institution, are enabled to assume the position of leaders in their several callings, and of educators of the people to a higher grade of culture, increasing the productive brain capacity as well as the material wealth of the country, cannot be estimated in dollars and cents. From all parts of the country come back most favourable reports of the graduates who have been sent out, and their influence, already great, is constantly on the increase. The people of this state cannot do too much for an institution which has already done and is continuing to do so much for them, by developing the material resources of Connecticut, and by extending its reputation throughout the entire country."

IN this month's number of the *American Journal of Science and Art* Mr. Sellack gives a short but interesting account of his photographic work among the southern star-clusters at the Argentine National Observatory, Cordoba, where, for this purpose, he has been for some time at the expense of some gentlemen from Boston, U.S.A. On his arrival at Cordoba Mr. Sellack found the lens of the photographic refractor he was to use, broken, but by dint of perseverance and ingenuity he managed to put the pieces together in such a manner as to enable him to obtain a well-defined, nearly circular, photographic image of stars of the first and second magnitude; and with exposures of eight minutes, even stars of the ninth magnitude, of white colour, give a photographic impression. We have received a lunar photograph obtained by Mr. Sellack, and although it will not bear comparison with the well-known photographs obtained by other astronomers who have devoted attention to the subject, nevertheless the impression submitted to us reflects great credit on Mr. Sellack, considering the difficulties he had to contend with in getting it taken. The picture has suffered somewhat by too long an exposure in the telescope and over development.

WE have received from Mr. Gerard Krefft, Curator of the Sydney Museum, what he calls "a splendid bit of mimicry," in the shape of a photograph of the chrysalis of *Papilio sarpedon*. The chrysalis seems to be attached to a leaf, and has itself contrived to assume the shape of a leaf, or rather of a part of the leaf to which it is attached. Its colour, Mr. Krefft says, is pale green, or sea-green.

THE last number of the Journal of the Linnean Society is entirely occupied by Mr. Bentham's important paper on the structure, classification, and history of development of the Compositæ, the largest and most natural order in the vegetable kingdom. In accordance with the system proposed in the "Genera Plantarum," he divides the order into 13 sub-orders, viz.: 1, Vernoniaceæ; 2, Eupatoriaceæ; 3, Asteroideæ; 4, Inuloideæ; 5, Helianthoideæ; 6, Helenioideæ; 7, Anthemideæ; 8, Senecionideæ; 9, Calendulaceæ; 10, Arctotideæ; 11, Cynaroideæ; 12, Mutisiaceæ; 13, Cichoriaceæ; the most important diagnostic characters depending on the structure of the pistil (in the hermaphrodite flowers), fruit, andrœcium, corolla, and calyx (pappus). A very exhaustive account is given of the geographical distribution of the sub-orders and principal families; and the first appearance of the order is traced with probability to Africa, Western America, and probably Australia; the difference between the forms now observed in the northern and southern hemispheres having become developed only after the tropical belt introduced an impassable barrier between them. It is one of the most important contributions to structural and systematic botany which has issued from this country for many years.

Dr. ROBERT SCHLESINGER publishes (from the house of Orell, Füssli & Co., Zurich) a small work on the microscopica examination of Textile Fabrics in the raw and coloured state, with a note on the mode of detecting "shoddy-wool." It contains a complete account of the fabrics made from the various vegetable fibres in more or less common use, also from hair and silk, with their distinguishing characteristics, as exhibited under the microscope, when raw, spun or woven, and dyed, illustrated with 27 woodcuts, and introduced by a preface by Dr. Emil Kopp.

THE current number of the *Zoologist* commences with a paper by Mr. F. H. Balkwill, having the pretentious title "A Difficulty for Darwinists," in which, like many others who do not fully understand the subject, he lays too much stress on the possibility of slight variations in an *infinite* number of directions. No doubt it is theoretically possible for an infinite number of variations to occur in living bodies, if they are within the influence of an infinite number of different forces, just as the result of a very large number of forces acting on a particle, may cause it to take one of almost an infinite number of directions. But the forces acting on the living body are comparatively limited, and when as in the cases of the Thylacine and the Dog, or of the Wombat and the Rodent, which are the author's stumblingblocks, the forces which have been called to act on the Marsupial and Placental types of organism have been practically identical, they having had to undergo the struggle for existence under similar circumstances, it is not to be wondered at, but only to be expected, that similar organisms should be the result, especially as the two types to start with are not separated by any great interval. It is just as probable, external circumstances being similar, that the isolated Marsupial ancestor should give rise to carnivorous, rodent, and herbivorous forms, as that they should be developed from a Placental type.

THE current part of Mr. Dresser's "Birds of Europe" commenced with the description of the Imperial Eagle (*Aquila mogilnik*), to which two plates are devoted, in one of which the young of that species is contrasted with that of the distinctly separated White-shouldered Imperial Eagle (*Ag. adalberti*), from Spain. This is followed by illustrated descriptions of the Algerian Black-headed Jay (*Garrulus cervicalis*), the Siberian Jay (*Perisoreus infaustus*), the White Stalk (*Ciconia alba*), several Anserine birds, and the Isabelline Lark (*Galerita isabellina*), which, by the way, does not occur in Europe.

IT is locally stated that among the collections made by the Chilian exploring expeditions on the west coast of Patagonia in the *Chacabuco*, is a specimen of the huemul, an animal which had altogether been lost sight of. There are five well-prepared skins in the National Museum of Chile. Molina mentions it in his "Natural History of Chile," published in 1782. He describes a species of horse (*Equus bisulcus*), or rather an ass, with its hoofs divided like ruminants. He says it inhabits the most inaccessible parts of the Andes, and is difficult to be taken. Mr. E. C. Reed, of the National Museum of Chile, pronounces it to be a stag of the genus *Cervus*, and as not belonging to any new genus.

THE record of the "Astronomical and Meteorological Observations made during the year 1870 at the U.S. Naval Observatory" occupies a bulky quarto volume of about 1000 pages, and contains in its numerous carefully-constructed tables sufficient evidence of the amount and value of the work done at the Observatory. The U.S. Government contribute liberally to the support of the Observatory, the work of which is performed by an efficient staff. One of the most interesting parts of the record of work for 1870 is that describing the details of the Transit Circle.

WE would recommend to all interested in education a pamphlet by Mr. Henry Leedam, a practical teacher, entitled "Complete School Education." It is evidently the result of much thought and observation, and of advanced views of what constitutes a complete education even for boys intended for business. We are glad to see that in his system he gives great prominence to science, as one of the most efficient instruments in general training.

THE Liverpool papers report that a sharp shock of earthquake was felt at Southport on the evening of Wednesday, July 16, accompanied by a loud report. It was thought at first by many that a colliery explosion must have taken place in some of the collieries near Ormskirk, so loud and distinct was the first report. The other three—for there were four shocks—followed much quicker after each other than did the second after the first. There was no undulatory motion such as accompanied the severe shock which occurred about two years since.

ON May 10 a strong shock of earthquake, lasting two seconds, occurred at Opiape, in North Chile.

A COLLECTION of stone implements from Costa Rica, in Central America, has been sent to the American Museum of Natural History in New York.

DON CARLOS MOESTA, formerly Director of the Astronomical Observatory at Santiago, in Chile, has been appointed Chilian Consul-General in Saxony.

THE sixth annual report of the Provost of the Peabody Institute of Baltimore, to the trustees, dated June 5 of this year, is in all respects very satisfactory, and shows that the Institute forms an important means of education, literary and scientific, in the city to which it belongs. The library is a large one, upwards of 50,000 volumes, and the number of readers has increased considerably during the year, the proportion of scientific works sought for being on the whole, as things go, large. During the year 120 lectures were delivered, of which 20 were popular, and 90 special class lectures in particular departments. Though scientific lectures seem to be much less attractive than lectures in literature, still the Provost rightly thinks they should be persisted in, especially as this is one of the main objects of the institution, which is well supplied with scientific apparatus. We have no doubt that by judicious arrangement of subjects and hours, and by securing competent lecturers who know how to make their subjects attractive, scientific lectures will become increasingly popular.

WE give the following on the authority of the *American Artisan*:—The President of Rutgers College, New Jersey, Dr. Campbell, recently found beneath some of the trees in the campus, numerous carpenter bees, each minus its head. Having called the attention of Rev. Samuel Lockwood, the eminent naturalist, to the fact, careful observations were made with interesting results. It was first noted that these bees were all of the same species, and were all honey-gatherers. The case at first appeared to be one of wanton massacre; the merciless executioners being common Baltimore orioles. On making a more thorough examination of the headless trunks, it was discovered that every body was empty, the insect having been literally eviscerated at the annular opening made at the neck by the separation of the head. The interesting fact disclosed by these observations is that these birds had learned that the body of these particular bees—the stingless males—were filled, or contained honey sipped from the blossoms of the horse-chestnut; and so they watched the insects until they were fully gorged, then, darting upon them, snipped off their heads, and always at one place, the articulation, thus showing themselves acquainted with the anatomy of their victims as well as their habits, and taking advantage of both for the gratification of their love for sweets.

THE *Journal of the Franklin Institute* says that the splendid telescope designed for the National Observatory at Washington will, in all probability, soon be erected and in use. The work upon the new tower and dome, intended for its reception, is being rapidly brought to completion. The object-glass—the largest in the world, twenty-six and a half inches diameter, and thirty-two feet focal length—is now finished, and ready for the instrument. The cost of the new instrument, with the necessary machinery, will be about 30,000 dols., and that of the tower and dome, erected to receive it, about 15,000 dols. If to this we add the list of new apparatus already acquired or in process of construction for the Observatory, for the observation of the coming transit of Venus, the Institution will shortly be as well or, perhaps, better equipped than any other of its kind in the world.

THE additions to the Zoological Society's Gardens during the past week include two Argus Pheasants (*Argus giganteus*) from Malacca, presented by his Excellency, Sir H. Ord; a Jaguar (*Felis onca*) from America, presented by Mr. J. H. Murchison; a Himalayan Bear (*Ursus tibetanus*) presented by Mr. G. R. Taylor; two Mulita Armadillos (*Tatusia hybrida*) from Buenos Ayres, presented by Mrs. Mackinlay; two White-crested Guans (*Pipile jacutinga*) from British Honduras, presented by Mr. S. Carmichael; a Patas Monkey (*Cercopithecus ruber*) from West Africa, presented by Mr. E. Hoad; three Black Vultures (*Cathartes atratus*) from America, presented by Mr. C. C. Lovesy; three Fournier's Capromys (*Capromys pilorides*) from Cuba, presented by Mr. J. R. Watkins; a Rhesus Monkey (*Macacus erythræus*) from India, presented by Miss E. D. Wishart; a Sable Antelope (*Hippotragus niger*), from South Africa, deposited.

RESEARCHES ON EMERALDS AND BERYLS *

Part I. On the Colouring-matter of the Emerald.

FROM the time of Vauquelin's analyses, the colour of the emerald was always regarded as due to the presence of oxide of chromium, until the publication of the memoir of Lewy, who ascertained that emeralds contained that element, and concluded that the colour was due to the presence of some organic substance. Lewy also affirmed that the deepest tinted emeralds contained the most carbon. Wöhler and Rose, on the other hand, having exposed emeralds to a temperature equal to the fusing-point of copper for one hour, without their losing colour, and also having fused colourless glass with minute quantities of oxide of chromium and obtained a fine green glass, considered chromium and not organic matter to be the cause of the colour.

Boussingault, in the course of an investigation of the "morallons," arrived at the same conclusion as Wöhler and Rose; and although admitting them to contain carbon, denied that it was the cause of their colour, inasmuch as they endured heating to redness for one hour without loss of colour. This result has been confirmed by Hofmeister. I have carefully repeated and extended these experiments. The emeralds employed were canutillos from Santa Fe de Bogota. Their specific gravity was 2·69.

One of the above emeralds was exposed for three hours in a platinum crucible to a bright reddish-yellow heat. At the end of the operation it was rendered opaque on the edges, but the green colour was not destroyed. This experiment completely confirms those of Wöhler and Rose and Hofmeister. The power of the colouring-matter to resist a red heat having made me inclined to disconnect the question of the colour from that of the presence of carbon, I made experiments to determine whether beryls contained that element, and, if so, to what amount. The experiments given further on, were made at this stage of the inquiry, and the result showed that the beryl analysed† contained the same amount of carbon as Lewy's emerald.

Although demonstration had been obtained of the presence of carbon in the beryl A, it was still possible that it might have been derived from the decomposition of a carbonate. To settle this question, an apparatus was so arranged that the beryl could be treated with sulphuric and chromic acids successively. It was found that no carbonic anhydride was liberated by sulphuric acid, but the addition of chromic acid caused it to appear immediately. The numerous precautions taken are fully described in the original paper.

Strictly comparative experiments were then made upon minute quantities of charcoal and graphite, the results indicating the carbon contained in the beryl A to be in a condition which is more slowly attacked than either charcoal or graphite, and it is probably in the form of diamond, as has been shown to occur with the carbon contained in artificially crystallised boron.

The presence of carbon in beryls does not appear to be invariable. After repeated experiments upon another large beryl from Haddam County, North America, I was unable to satisfy myself that it contained carbon.

The next point I wished to ascertain was the relation borne by the quantity of carbon in the beryl A to that in the emerald. For this purpose I employed a similar apparatus to that used by Dumas in his researches on the atomic weight of carbon previously alluded to. The following percentages were obtained:—

	Beryl A. I.	Beryl A. II.	Emerald.	Lewy. Emerald (mean).
Carbon anhydride . .	0·31	0·31	0·26	0·28
Water	1·35	1·73	1·20	1·89

II.—On the Effects of Fusion upon Emeralds and Beryls.

On the Effects of Fusion upon Opaque Beryls.—In order to study the effects of fusion upon beryls or emeralds, I found it necessary to use the oxyhydrogen blowpipe. My first experiments were made upon the beryl A; it weighed 62·54 grms., and its density was 2·65.

The phenomena observed on submitting a fragment of beryl to the action of the flame are very beautiful. Having so adjusted the flame that the beryl fuses tranquilly, and is yet at the exact point of maximum heat (if the substance is not too large for the apparatus), it no longer lies as a shapeless mass on the car bon support, but gathers together, rises up, and forms a perfect bead—round, clear, and brilliant. To obtain the adjustment of position necessary for this result, it is indispensable to wear very dark glasses, so dark, indeed, that objects can scarcely be discerned through them in broad daylight. Without this precaution, the minute details of the globule cannot be observed. The heat and glare would also seriously affect the sight. If all is working properly, the bead should be quite mobile; and advantage of this must be taken to keep it incessantly rolling, and yet not remove it from the point where it gives out the most brilliant light. By this means the whole globule is rendered transparent. If, on the other hand, it is allowed to remain without motion on the carbon (unless the globule be very minute), it will be found, when cold, to have a white opaque base, passing into the centre of the bead in a conical form, and entirely destroying its beauty.

The globules thus obtained from the beryl A were clear and colourless, but generally contained a few minute air-globules and striæ, which become obvious under the lens. Towards the end of this part of the investigation I succeeded in almost entirely avoiding these defects; but I have been compelled for a time to abandon experiments in this direction in consequence of the strain thrown upon the eyes.

When chromic oxide is added to the beads, and they are again carefully fused, they acquire a fine green colour; the tint is, however, inferior to that of the emerald. The green beads may, by an intense and prolonged heat, be rendered colourless. With cobalt oxide the beads afford beautiful blue glasses of any desired shade; and in all cases the results are the same as with the artificial mixture of beryl ingredients to be described further on.

The effect of fusion upon the beryl is to lessen the hardness and lower the specific gravity. The globules may be scratched by quartz. The specific gravity was found to be 2·41.

The beryl, therefore, lost nine per cent. of its density in passing from the crystalline to the vitreous state.

I was desirous of carefully comparing this loss of density undergone by beryls with that of rock crystal fused under the same circumstances. I have repeated with great care the determination of the specific gravity of rock-crystal, both before and after fusion. Before fusion it was 2·65, and afterwards, 2·19.

Rock-crystal loses, therefore, no less than seventeen per cent. of its specific gravity on passing from the crystalline to the amorphous state, or about half a per cent. less than is undergone by garnets, according to the observations of Magnus; whereas the beryl A only lost nine per cent., or little more than half as much.

On the Effects of Fusion upon Emeralds.—On heating alone before the oxyhydrogen blowpipe, emeralds bear a bright red heat without losing their colour; and at a heat which causes incipient fusion, the edges turn colourless and opaque, while the centre remains green. After fusion for a short time they yield an opalescent greenish glass, which, kept for a long time at the maximum temperature of the blowpipe, becomes quite transparent and almost colourless. The addition of chromic oxide causes the bead to become of a dull green colour, which is not improved by moderate heating. The fact that emeralds endure a temperature capable of fusing the edges, without the centre losing colour, appears conclusive against the idea of the colouring-matter being organic. The beads produced by the fusion of emeralds resemble those formed in the same manner from beryls; the phenomena during the fusion are also nearly alike; but it takes longer and a higher temperature to produce a colourless transparent bead with emeralds than with colourless beryls. The beads can be scratched by quartz, and the density is reduced to 2·40. The density of fused emeralds is therefore almost exactly the same as the globules obtained in a similar manner from the beryl A.

On the Effects of Fusion upon an Artificial Mixture of Beryl Ingredients.—Being desirous of trying the effects of fusion upon an artificial mixture of the same composition as that of a beryl, I made a series of careful analyses of the beryl A. Even my earlier analyses enabled me to obtain a sufficiently close approximation to the compositions of the beryl A. The following were the proportions used:—

Silica	67·5
Alumina	18·5
Glucina	14·0
	100·0

* Abstract of paper read before the Royal Society, June 19. By Greville Williams, F.R.S.

† As this beryl will be repeatedly alluded to in this paper, and especially in the second part, I shall, for convenience of reference, call it "beryl A." It was found in Ireland.

I did not introduce any iron or magnesia, as I regard them as accidental impurities varying in amount.

When a mixture of the above composition is exposed to the flame of the oxyhydrogen blowpipe, it fuses with almost exactly the same phenomena as with the natural beryl. It is, however, as might be anticipated from the absence of iron and chromium, much easier to get a colourless transparent bead with the mixture than with either emeralds or beryls. The greatest difficulty in this respect is, of course found with emeralds. The specific gravity of the artificial fused globules was 2·42, or almost exactly the same as the density of native emeralds and beryls after fusion.

When a small portion of chromic oxide is added to the artificial mixture and the whole is subjected to fusion, the resulting bead is of a rich yellowish green, and in many experiments approached to the emerald tint; but, as a rule, the colour is more of a faded leaf-green: and, although I have never obtained a globule of the vivid tint of a fine emerald, the glasses, when well cut, are quite beautiful enough to serve as jewels. Prolonged heating gradually diminishes the colour, the bead gradually becoming of the palest bottle-green, and, finally, nearly colourless. This result is the same as with the emerald.

The metallic oxide which yields the finest tints when fused with opaque beryls, or the artificial mixture, is that of cobalt. The manner in which this oxide withstands the intense heat of the oxhydrogen flame is remarkable. All tints, from nearly black to that of the palest sapphire, can be obtained, and the resulting glasses, when cut, are extremely beautiful, and have almost the lustre of crystallised gems.

The globules obtained by fusing the artificial mixture of beryl ingredients with didymium oxide show the characteristic absorption-spectrum of that metal in a very perfect manner, the lines being intensely black. Even when the bead is quite opalescent from insufficient heating, the black lines are beautifully distinct in the spectroscope. With a large quantity of didymium oxide the beads are of a lively pink, becoming more intense by artificial light, and, when cut, form very pretty gems. The presence of didymium in sufficient quantity raises the specific gravity to 2·59, being nearly the same as that of the emerald before fusion.

Conclusions.—The evidence given in this paper, showing that colourless beryls may contain as much carbon as the richest tinted emerald, taken in conjunction with the ignition experiments, and the results of the fusion of chromic oxide with colourless beryls, and with an artificial mixture of the same composition, leave me no room to doubt the correctness of Vauquelin's conclusion, that the green colour of the emerald is due to the presence of chromic oxide.

The fact that emeralds and beryls lose density when fused cannot properly be cited as proving that they have been made in nature at a low temperature; for it is quite possible that they were crystallised out of a solution in a fused mass, originally formed at a temperature high enough to keep the constituents of the emerald in a state of fusion, and that the crystals developed themselves during a slow process of cooling or evaporation. The method employed by Ebelmen for the artificial production of chrysoberyl, namely, heating alumina, glucina, and carbonate of lime with boracic acid in a porcelain furnace until a portion of the menstruum had evaporated, yielded crystals of the true specific gravity, showing the density of minerals to be less dependent on the temperature at which they are produced than upon their crystalline or amorphous state.

One crystalline gem (the ruby) has undoubtedly been produced in nature at a high temperature. I have frequently repeated Gaudin's experiment on the artificial formation of this stone, and can confirm most of his results. I did not, however, find the density to be quite the same as the native ruby or sapphire, which is, in different specimens, from 3·53 to 3·56. Artificial rubies of the finest colour made by me by Gaudin's process had a specific gravity of 3·45, which is not 3 per cent. lower than that of the ruby. The reason for this close approximation will be found in the fact that fused alumina crystallises on cooling. The crystallisation is, however, confused and imperfect, which causes the resulting product to be only partially transparent, and to have a slightly lower specific gravity than the natural gem. It is consequently scarcely correct to call the fused stones made by Gaudin's process "artificial rubies."

I have convinced myself that rubies have been formed in nature at a temperature equal, or nearly equal, to that of the fusing-point of alumina, from the circumstance that the reaction between chromic oxide and alumina, which results in the development of the red colour of the gem, is not effected at low or even moderately high temperatures, but requires a heat as high as that of the oxyhydrogen blow-pipe. It is not necessary that the chromium should be presented to the alumina in the form of chromic acid. It appears, therefore, that the red colour of the ruby is not caused by the presence of chromic *acid*. It is, in fact, a colour reaction *sui generis* between alumina and chromic oxide, which, as far as my experiments have gone, only takes place at very elevated temperatures.

SOCIETIES AND ACADEMIES

London

Royal Horticultural Society, June 18.—Scientific Committee.—Dr. Hooker, C.B., F.R.S., in the chair.—Dr. Capanema, from Rio Janeiro, described the destruction in Brazil of orange, peach, and cotton plants, more especially at Milagres, in the province of Ciara, from the attacks of a Coccus. An orange tree of historic interest more than 200 years old had been destroyed by this insect.—Dr. Masters, F.R.S., reported upon a double-flowered variety of *Lobelia erinus*. The calyx was normal, the corolla was affected by a *dédoublement*, the stamens were more or less petaloid, the ovary was represented by obscure carpellary leaves bearing ovules on the margins.—Mr. Lane, of Berkhampstead, sent a cutting of a yellow-leaved variety of Laburnum which had broken from an old stem of the ordinary kind previously budded some time before with the yellow one. The buds which were inserted died, but as in other cases the tendency to variegation in the foliage had been communicated to the stock.—The Rev. M. J. Berkeley stated that he had provisionally referred the thread blight which had attacked the tea plantations in India to *Corticium repens* Berk.

July 2.—A. Smee, F.R.S., in the chair.—Prof. C. Babington sent flowers of a potato in which the petals were replaced by stamens.—Dr. Denny sent a Pelargonium which showed an interesting reversion to one of the original wild forms (*P. inquinans*). It had been raised from Wellington as the seed parent, and Marathon as the pollen parent, both varieties of the nose-gay class.

Edinburgh

Scottish Meteorological Society, July 2.—Sir Thomas Buchan Hepburn in the chair.—The Council reported to the General Meeting, that there are 92 Stations in Scotland in connection with the Society, 5 in England, 4 on the Continent, 2 in Iceland, 1 in Farö, and 1 in South America; that there are 9 honorary, 16 corresponding, and 557 ordinary members; that the value of the Instruments at the Society's Stations amounts to 1,173*l.*, of which 218*l.* belongs to the Society, and the rest to local parties; and that during the past ten years, 63 certified Barometers, 59 louvre-boarded boxes, on Stevenson's pattern, for holding thermometers, had been despatched to the Society's Stations, and about 800 thermometers compared in the office. In reply to an application from a Committee of the British Association, the Council have intimated that they will, as hitherto, be glad to make the unpublished meteorological observations in their possession available to scientific men, and free of charge, in so far as the limited means of copying at their disposal will enable them to do so.—Mr. Buchan gave in the report from the Committee which had been appointed to inquire into the subject of the Herring Fisheries in relation to Meteorology. The returns of the fishings at Wick, Buckie, Peterhead, and Eyemouth, for six seasons of thirteen weeks each (1867-1872) had been examined, and the catches of herring compared with the mean daily temperature of the sea and that of the air with the height of the barometer, the direction and force of the wind, storms of wind, thunderstorms, Auroras, and rain. The fishing season at these places, in common with the whole of the east coast of Great Britain, from Scotland to Flamborough Head, occurred during July, August, and September, ending somewhat earlier at the northern than at the southern stations. From the mean daily catch at Wick and Buckie, from which daily returns had been made, it is seen that during the six years the largest average catches were taken between the 13th and 22nd August, and the whole herring season began about the 19th July, and ended on the 2nd September. That period agreed exactly with the highest mean daily temperatures of the sea during the year, and the period of the

heaviest catches coincided with that of the absolute maximum temperature of the sea. It is premature to affirm that there is any absolute connection between those two facts, seeing, for example, that the herring season at Stornoway occurred in May and June, but it is, to say the least, a striking coincidence. The relations of the temperature of the sea to the migrations of the herrings will receive further elucidation when, the returns from Stornoway and other places being discussed, it is exactly determined with what critical epochs of the annual march of the temperature of the sea, the herring seasons, and the periods of maximum catches in different districts correspond. In almost all cases the largest catches occurred with a high, steady barometer and light winds, indicating settled weather; and very light catches, in the height of the season, with thunder-storms, a low and unsteady barometer, northerly and easterly winds, and weather more or less stormy. It was recommended that, in the further prosecution of the inquiry, attention be given to investigate the causes which determine the time of the commencement of the fishing, the fluctuations of the catches in different districts or on different days, and the end of the fishing season. Self-registering thermometers, similar to those now in operation at Peterhead Harbour, established at different points on the coast, and observations on the temperature of the sea, by the more intelligent fishermen on their fishing excursions, could not fail to contribute very material assistance to this difficult inquiry. The Committee was re-appointed to continue their investigation of this important question, Mr. Thomas Stevenson, convener.—Mr. Robert Louis Stevenson then read a paper on "Local Conditions influencing Climate in Scotland;" in which the effect of shelter from the East and West, and of relative proximity to the sea, were chiefly considered. The mean annual temperature of Unst and Monach, two of the Society's stations, which, being situated on outlying islands, are almost wholly removed from the influence of the land, was found to coincide with the mean sea temperature in their neighbourhood. A series of observations was proposed at three or four stations, provided with thermometers similarly placed and protected, one set being close to the shore, another a mile inland, and the others at intermediate distances, in order to decide in what manner the climatic influence of the sea extends inland. Mr. Milne Home stated his belief that the Society would be able to carry out the proposal.

Berlin

German Chemical Society, July 14.—C. Böttinger has obtained a new acid from pyruvic acid, by heating it to 130° with a small quantity of baryta. It is well crystallised, and having two atoms of hydrogen more than uritric acid, has obtained the name of hydruritic acid. Its mode of formation is expressed by the formula

$$4C_3H_4O_3 = \underset{(\textit{new acid})}{C_9H_{10}O_4} + \underset{(\textit{oxalic acid})}{C_2H_2O_4} + CO_2 + 2H_2O.$$

A. Kekulé and A. Fleischer have treated camphor with iodine and thus transformed it into oxy-cymol, a phenolic body boiling at 231° of the formula $C_{10}H_{14}O$. Prof. Kekulé considers this reaction as a proof for a new graphic formula for camphor, which he intends to prove by further researches.—F. Landolph reported on the action of nitric acid on various cymols. Camphor-cymol yields mono-nitrocymol and mono-nitro-toluyic acid, which is volatile below its fusing point. Cymol from ptychotis-oil yields dinitro-cymol and a mononitro-toluyic acid different from the above and fusing at 184°.—F. Fittica has obtained identical products from the cymols of camphor, ptychotis-oil and thymol. All of them yield two different mono-nitro-cymols, one solid, the other liquid.—A. Kekulé has found amongst the products of PCl_5 on phenol-parasulfuric acid a body of the formula $PO . \genfrac{}{}{0pt}{}{OC_6H_4Cl}{Cl_2}$, yielding with water a corresponding acid and chlorophenol.—V. v. Richter has found that benzoate and formate of potassium fused together yield both terephthalic and isophthalic acids, a fact which renders untrue many conclusions on the constitution of aromatic bodies which have been founded on the production of either one or the other of the above acids with derivatives of benzol and formate of potash. Prof. Richter thinks that either one or the other of those isomeric acids are formed according to the temperature employed in fusing.—F. Baumstark has found in urine a new neutral crystallised substance of the formula $C_3H_8N_2O$, which with alkalis yields lactic acid and ethylamine.—K. Birnbaum reported on the attraction of water by superphosphate of calcium exposed to moist air.—G. Barbaglia reported on the impurities contained in commercial isobutylic aldehyde (chiefly acetone) derived from propylic alcohol, and on the conditions under which isobutylic alcohol yields acetone.—A. Oppenheim communicated the continuation of his researches on cymoles derived from various $C_{10}H_{16}$ isomers. Those from terpene and from citrene yielding both paratoluyic as well as terephthalic and acetic acids, can only differ in the position of the 2 atoms of hydrogen which they contain in addition to cymol. This renders improbable that all $C_{10}H_{18}$ yielding cymoles should be constituted according to the view lately expressed by Kekulé.

Paris

Academy of Sciences, July 7.—M. Bertrand, president.—The proceedings commenced with the announcement, by the perpetual secretary of the award of the Albert Medal of the Society of Arts to M. Chevreul.—During the meeting the commission charged with the recommendation of a candidate for the place left vacant by the decease of M. de Verneuil, presented its report. It recommends, 1st, M. de Lesseps; 2nd, MM. Bréguet, du Moncel, Jacqmin, and Sedillot.—The following papers were read:—Theory of the planet Saturn, by M. N. J. Leverrier.—On an isochronous regulator constructed by M. Bréguet for the Transit of Venus at Yokohama, by M. Yvon Villarceau.—On the method of action of the water during the reactions accompanying the mixing of neutral, acid, and alkaline solutions, by M. Becquerel.—On the definition attainable with small astronomical telescopes, by M. d'Abbadie.—A direct demonstration of the fundamental principles of thermo-dynamics; the laws of friction and concussion, by M. A. Ledieu.—Thermal researches on saline solutions by M. P. A. Favre.—On the fossils of the phosphatic chalk of Quercy, by M. P. Gervais.—On the development of the plague in the mountainous countries and plateaus of Europe, Africa, and Asia, by Dr. Tholozan.—On the iron ores of the department of Ille-et-Vilaine, by M. Delage.—Experiments on the action of ammonia and the prolonged action of water on the Phylloxera, by M. Gueyraud.—On magnetism, by M. du Moncel.—On the variable period of the closing of a Voltaic circuit, by M. Cazin.—On an "absolute" barometer, by MM. Hans and Hermary.—On the dissociation of mercuric oxide, by M. H. Debray.—On a method of comparing different gunpowders, by M. de Tromenec.—On the oxalins, or ethers of glycerin and the polyatomic alcohols, by M. Lorin. Oxalin is produced by the action of oxalic acid on glycerin.—On the zoological position and rôle of the acarians known as *Hypopus*, *Homopus*, *Trichodactylus*, by M. Mégnin.—Experimental contributions to the history of digestion in birds, by M. Jobert.—Observations on certain of the organic liquids of fish, crustacea, and cephalopoda, by M. F. Papillon.—On the heat of combustion of explosive substances, by MM. Roux and Sarrau.—New experiments relating to the theory of the thrust of earthworks, by M. J. Curie.

THE ENDOWMENT OF RESEARCH

IV.

IN accordance with the heading, deliberately adopted for this series of articles, the main object of them has been to insist upon the national importance of a direct endowment of research, and to indicate a way whereby scientific investigators, relieved from any incidental duties, may be placed upon a footing of security and competence. In justice, however, to the letter from Professor Flower, published in our last number, it is necessary to give some explanation why the indirect endowment of scientific men by means of the existing professoriate has been comparatively ignored.

Though it is very far from our intention to quarrel with the main drift of that letter, yet it were vain to attempt to disguise the real point of disagreement between Prof. Flower's proposals and those herein advocated. To augment the salaries of distinguished men of Science, whether government officials, executive members of the wealthy scientific bodies, or University professors, and to increase their numbers, is no doubt an object to which certain classes of the public require that their attention should be drawn, as it is also one of the means by which original scientific work would be encouraged. At this point, apparently, Professor Flower would for the present stop; yet we think that there are many and weighty reasons why those who are not content with such a scheme as final, should hold that a favourable time has now arrived for putting forward a more complete system sufficiently elastic to comprehend within its future development the liberal subsidy of all forms of unremunerative Scientific Research.

As to the funds at the disposal of scientific bodies, it is well known that they are so small as to form a scarcely appreciable element in the consideration of the present question, nor is it likely that they will receive much increase; but yet it would be desirable that the method of their distribution should form an example to guide the application of a more complete system. Again, with reference to the Government appointments, the prospect does not appear more encouraging. Our practical politicians are not unnaturally offended by the anomaly that the holders of these offices should confessedly receive pay, not for the work they do, but in honour of their general scientific attainments. The Mastership of the Mint has not been saved even by the illustrious character of its previous occupants, and along with it have gone several subordinate posts which also were honoured by the scientific men who held them. It only remains for some Chancellor of the Exchequer or Minister of Public Works to arise, wholly given over to the less noble doctrines of Political Economy, and Science will lose the remainder of those places which open competition could fill so much more cheaply, and then the public scientific work of which the popular voice demands the accomplishment, may be resigned to the enterprise of pushing newspaper proprietors. This sort of indirect endowment of research may be said to have had its day; it was of a piece with the public sinecures which used to be awarded indiscriminately for literary or other ill-recognised merit. It was extremely useful when no particular kind of work was required in return, and when the national benefits arising from the advancement were less thought of than they are now.

It is, without doubt, to the professoriate at the Universities that the advocates of indirect endowment must turn in the first place, both for the wealth and the organisation they require, and it is on this ground that issue with them must be joined. It is our purpose, therefore, to point out, first, that the Science professors at the Universities are already in a fair way to get both the position and the emoluments which they deserve, and secondly, that to subordinate original research to the paramount duty of teaching is a clumsy expedient which should not, on principle, be systematically adopted.

In the first place it hardly needs to be said that all the tendency of ancient and modern endowment has been in favour of the Professoriate, so that the interests of teaching are already in possession of the field. In the old days when all instruction was of necessity oral, to found a chair was the one means by which the highest forms of new learning could be promoted; and the force of this tradition, acting in harmony with the practical character of Englishmen, who always expect visible results from money spent, has been a guarantee that modern Science, while growing to its present dimensions, should not fail to receive this sort of attention at the Universities. At Oxford, for example, the present holders of the three leading chairs of Chemistry, Physiology, and Physics receive from various academical sources endowments of 800*l* each per annum, and if the other Science Professorships are inadequately endowed, the same may be said of many of those subjects which enter directly into the course for the Arts degree. According to a rough estimate of Mr. M. Pattison's, Science on the whole receives nearly 5,500*l*., whereas Philology, the next highly endowed faculty, gets but 4,000*l*.* It must also be borne in mind that the University Commission of twenty years ago gave a stimulus in this direction which has not died away. Both the University and College authorities are not unmindful of the duty of extending the Professoriate, and endowing it worthily: new chairs are even now in process of foundation, and at Oxford at least it is the rule rather than the exception to confer a full fellowship upon a hardworking professor in whatever department of knowledge, whose statutable endowment is comparatively small. From these statements it would be manifestly wrong to draw the inference that either the physical sciences or the other branches of scientific study are as yet fully represented or adequately endowed at Oxford and Cambridge: the purport of them rather is to show that teaching at the Universities in Science as in other matters has gained a position which can well take care of itself. If the plan were adopted which has worked so well at Glasgow, viz. to allow the professors an official house, and to leave to the fees of their pupils the further augmentation of their salaries, Prof. Flower's demand for a simple competency would be completely satisfied.

The real difficulty, however, will yet remain, for on the one hand we have not yet attained any assurance that we

* It should be noticed that the anomalous chairs of Divinity have been throughout excepted from these calculations.

shall get from our endowments anything more than first-rate teaching, and on the other hand we have a large proportion of the University revenues yet to dispose of. It would, of course, be a possible alternative to endow so large a number of professors as to reduce their teaching duties to a vanishing point, and thus avoid the appearance of a radical change and escape the reproach which apparently attaches to the direct endowment of Research. It is not to be supposed that the advocates of indirect endowment intend deliberately to take up with such a subterfuge, yet on any other hypothesis it is as certain as anything can well be, that the original investigation which they put in the second place will come off second best. It were invidious to allude to particular instances, but it is past denial that the original discoveries in Science which once made England famous, and now more or less maintain that fame, neither were nor are achieved by the holders of teaching posts, and it is equally clear that many of the forms into which modern Science is developing are not of such a character as to be capable of being transmitted by oral instruction. The truth seems to be that the intimate connection sought to be established between original investigation and professorial teaching is borrowed from the artificial institutions of another country. It is the chief characteristic of a German University that the full professor, the extraordinary professor, and the *privat docent* make up the class which is there engaged in scientific study not less than in academical teaching, a peculiarity which may be partly attributed to the laborious character of the people, but yet more to the pecuniary poverty of the Institutions. It is in fact from the want of endowments that the emulous spirit of German patriotism has been compelled to exact double work from a single instrumentality. The renowned University of Berlin is indebted for the whole of its resources to the state, and that, a state which is the most frugally administered of any in Europe: and from this cause it has learnt to elaborate an organised system of student teachers and inchoate professors, from whom research is expected as a duty co-ordinate with instruction, while the natural docility and perseverance of the German character have caused these expectations to be abundantly realised. Yet one of the most celebrated of modern German professors is reported to have said, that "the life of a professor would be a very pleasant one, if it were not for the lecturing." No doubt there are many English professors who secretly to themselves would re-echo the sentiment; yet what could sound more absurd if regarded from the ordinary point of view which is popular in this country? Germany indeed has set an example of the novel forms of scientific industry which should flourish at a living University, but the attempt to transfer to Oxford and Cambridge the German system in its integrity would in some respects be a backward step, and would probably prove a failure. The history of our Universities is against it, and their wealth alone serves to vitiate any analogy borrowed from the parsimonious Teuton. They possess, however, a large number of appointments, unconnected for the most part with teaching duties, and originally destined to be held on the condition of study. It would be easy by means of amalgamation and modification of tenure to make these appointments worthy of the acceptance of those who devote their lives to scientific research; nor ought it to be styled "a visionary ideal," to recognise that natural division of labour, which is permitted to us by the magnificent wealth at our disposal, agreeable to English precedent, and in close accordance with the intentions of the founders of Colleges.

C.

CARNÉ'S "TRAVELS IN INDO-CHINA"

Travels in Indo-China and the Chinese Empire. By Louis de Carné, Member of the Commission of Exploration of Mekong. With a Notice of the Author by the Count de Carné. Translated from the French. (London: Chapman and Hall, 1872.)

THE work, a translation of which is before us, is a history of the expedition despatched in 1865, under the auspices of the French Government, for the purpose of exploring the river Mekong, of which expedition Mons. Louis de Carné was a member. In consequence of his death the work has been carried through the press by his father, the Count de Carné. Mons. Louis de Carné, with every allowance being made for a father's very natural expressions of eulogy and admiration, seems to have been a young man of rare ability and promise, and his untimely death at the early age of twenty-seven, the result of the hardships he had to encounter during the expedition, marks a devotion to the cause of Science worthy of the emulation of all those who are desirous of helping forward scientific inquiry and research. The expedition, the history of which is here detailed, originated in a suggestion by the Governor of the French colony of Cochin-China to his Government, that the river Mekong, at the mouth of which Saïgon, the capital of the colony, is situate, might be made the principal route for the commerce passing between Europe and China. There can be no doubt that, could this route be satisfactorily established, the advantage to Europe would be immense, for in addition to a saving of about 1,200 miles in point of distance, the perilous navigation of the China seas, so much dreaded on account of the terrible monsoons by which they are periodically ravaged, might be entirely avoided. Accordingly, in the year 1865 the Marquis de Chasseloup, the French Colonial Minister, sanctioned the scheme of an expedition which should serve the interests of Science, as well as those of the colony, and which, ascending the Mekong from its mouth, where it empties itself into the Indian Ocean, to its sources amid the mountains of Thibet, should report fully on the navigability of that great river, which was then almost unknown beyond the Lake of Augeor, through which the boundary line between the kingdoms of Siam and Cambodgia passes. M. de Carné thus sums up the objects of the expedition:—"It was desired, first, that the old maps should be rectified, and the navigability of the river tried, it being our hope that we might bind together French Cochin-China and the western provinces of China by means of it. Were the rapids, of whose existence we knew, an absolute barrier? Were the islands of Khon an impassable difficulty? Was there any truth in the opinion of geographers who, with Dumoulin, believed that there was a communication between the Meïnam and the Mekong? To gather information respecting the sources of the latter, if it proved impossible

to reach them; to solve the different geographical problems which would naturally offer, was the first part of the programme the Commission had to carry out. We were required, besides, to report any miscellaneous facts which might throw light on the history, the philology, the ethnography, or the religion of the peoples along the great river, which was to be as much as possible the guiding-thread of our expedition. We had instructions to seek for a passage from Indo-China to China; an enterprise in which the English have always failed as yet."

M. Drouyn de Lhuys, the Minister of Foreign Affairs, heartily approved of the scheme, and appointed young de Carné to represent his department on the expedition. The exploration party started from Saïgon in June, 1866, but they were doomed to disappointment, so far as regarded their main object, for it was ascertained that the Mekong abounded in rapids, cataracts, and obstructions of various kinds, which precluded all possibility of a route being found to China in that direction, and after encountering severe sufferings and hardships to which some of their number succumbed, including M. de Lagrée, the chief of the expedition, they returned to Saïgon after an absence of about two years and a half.

M. de Carné claims, as the actual results of the enterprise, so far as it was successful, to have "corrected the errors, and set at rest, by lifting the veil from the doubts which had hitherto led geographers to false and uncertain conclusions in describing the eastern zone of the Indo-Chinese peninsula. The capricious windings of the Mekong; the prolongation of its course to the west, at the 18th parallel of latitude; the importance of its affluents; the strength and volume of its waters, and, if I may venture to say so, the proof of its individuality, which, contrary to the received opinion (viz. of the union of the waters of the Mekong and Meïnam), continues to the end of its course; the certainty of its entry into Yunan, where it receives the waters of Lake Tali, and into Thibet, where it has its source—all these points were cleared up. In a word, we brought back precise information respecting the whole course of an immense river, which rises amidst the snows, and completes its course under a burning sun. On the other hand, there are the exact observations and seemingly well-founded information respecting the other rivers of Indo-China; as to their position in different parts of their course, and the limits of their basins; and, in addition, many particulars respecting a part of China itself, which had been hitherto the least known."

We understand that an official report of the expedition is in course of preparation, and we have no doubt the present work will be found to form a very useful supplement to it. The volume would, however, be rendered more valuable and complete by the addition of a few maps, the only one it at present possesses being a somewhat rough sketch of the route followed by the exploring party. Whether France will be able, as M. de Carné suggests, to establish a communication between her colony and China by the river Songkoï, which flows along the north of the Annamite peninsula, is a problem which yet remains to be solved.

G.I.F.C.

"MOTHER EARTH'S BIOGRAPHY"

Chronos: Mother Earth's Biography. A Romance of the New School. By Wallace Wood, M.D. (Trübner and Co.)

THERE can be but few with active minds who have not occasionally found, after having grasped the essential points of any inclusive theory, that in moments of ease and quiet thought, it is far from unpleasant to attempt to apply it, by a running analogy, to some series of phenomena entirely different from those to which it was originally intended to relate, and by taking detail after detail, rebuild it on a fresh foundation. Few, however, have the confidence to put their results on paper, and fewer still to submit them to the criticism of a ruthless public.

The theory of evolution has an intrinsic fascination of this kind, especially to those with a cynical turn of mind; for though developed on a purely physical basis, nevertheless its entire applicability to the intricacies of society, puts the facts of every-day life in a manner so bold, and yet so evidently truthful, that, as it were, scales fall from the eyes of its disciples, and the panorama of moral philosophy flashes out in a manner so vivid and unmistakable as never to be effaced. The picture is a monochrome, and negativism is the colour!

As the title of this work indicates, the history of the world from the beginning of time has to be sketched, and the author commences with a vivid exposition of the nebular hypothesis, and the cooling down of the earth to the commencement of geologic time, under the headings of its Birth and Infancy. He then describes the commencement and development of vegetable and animal life. Just as in a tree all life is found in the terminal twigs, so "the species of animals we see on the earth are the twigs of the great animal tree, the body and branches of which have long since perished," and the struggle for existence by which the present forms have been arrived at, leads to the adoption of the fundamental maxim, "Be hungry and you will be great," which is proposed in place of the old adage—"Be virtuous and you will be happy." Further on the same principle is illustrated in a very different manner: "only iron-clad and zinc-covered trunks are seen on the Western American railroads, all others being smashed up by the remorseless pitching of the baggage-men, employed, it would seem, for the purpose; this is the *Survival of the Fittest.*"

After the world had passed through the early ages of only protoplasmic and invertebrate forms, the vertebrate era commences with "the fishy period." From the amphibian type was developed the reptile, as we are told, thus: "The lizard differed from the frog, and the newt &c., chiefly by breathing entirely through lungs instead of gills, and thus dispensing with water, except as a beverage; forced to magnificent temperance by long ages of death; driven to it by the great propelling power to which we are all more or less victims—the force of circumstances. Thus a second nature is given, and a new type is created. The fish became a reptile. There was no more longing for the good old times; a more glorious prospect in life the world has never seen. The untrod earth was a garden of thick fleshy plants; whole oceans of appetising insects and delicious worms awaited only

the eating. And the new-comers grew and throve as never has any immigrant race before or since." The tendency in animals, as we ascend in the scale of life, to assist one way or another in the further maintenance of their offspring, either by development of a nutritive yolk or by feeding them after they are hatched, is certain. "The explanation of this is very simple. As the population of the earth ever increases and competition grows sharper, it is those who have this assistance in their younger days that are enabled to succeed in the world, and to arrive at maturity. And these possess the inheriting tendency to do the same, or very likely a little more, for the new generation than their parents had done for them. 'If I could only give John a thousand dollars when he is twenty-one, I shall be satisfied,' says the sire; 'my father was only able to give me a hundred and a freedom suit.'"

The Reptilian Period is followed by "the Age of Brutes," wherein the maxim "might is right" was the ruling power. This is followed by "the Anthropological Age," that of the present time; a time of advance according to evolution, and not of decadence, for all we know tends to show that "the course of history is one of progress, and that consequently man is an elevated and not a fallen being; that he is a perfected creature and not a degraded divinity; that his course is Excelsior, onward and upward, and not downward." And if we consider the age of Man, in contradistinction to that of brute and reptile, to have been that in which man first appeared on earth, what may the present be considered—but the age of Woman. "Historically considered, her case is very strong. If the position of woman continues to become exalted in the future at anything like the rate it has advanced in the past—granted that she began as the slave of a brute—that future will show not an equality, but woman the ruler, the subordinate man; and these are advantages in her favour which none but the naturalist dreams of."

"A complete equilibrium—when for every desire there shall be a gratification," is the author's deduction as to the future, things being as they are; but "it would seem that life on earth is doomed to die a violent, and not a natural death. Man proposes, but the attraction of gravitation disposes," and so "we must be resigned, remembering that after all we are but a mere speck in the *great* celestial economy, which will lose nothing by our death."

The above short account of this eccentric and amusing work, which excels more by the quaint way in which well-known facts are put, than by anything original in itself, will be best supplemented by a perusal of the original.

OUR BOOK SHELF

The Elements of Chemistry. Theoretical and Practical. By William Allen Miller, M.D. D.C.L. LL.D., late Professor of Chemistry in King's College, London. Revised by Herbert M'Leod, F.C.S., Professor of Experimental Science, Indian Civil Engineering College, Coopers Hill. Part I. Chemical Physics. Fifth Edition, with additions. (London: Longmans, 1872.)

ALTHOUGH Parts II. and III. of this well-known manual have needed frequent alteration and revision as the science advanced, Part I. has, until quite recently, experienced but little change from its well-known form. The recent great advances which have been made in what is now so well known, or at least so often heard of, as solar chemistry, have necessitated considerable additions to the edition of 1867, the last that left the hands of the lamented author.

The name of Mr. M'Leod is a guarantee that the work has fallen into good hands. At page 196, a most complete and well-condensed statement of the present aspect of the subject will be found. The early Indian observations of Captain Herschel and others are referred to, and an account of the discovery of the method of observing the chromosphere without an eclipse is given, and also a sketch of the nature of the phenomena thus observed. A very good statement of the present state of our knowledge with regard to the thickening of the F line, and of Frankland and Lockyer's researches on that subject, is also given, and reference is made to their remarkable observation of the different lengths of the metallic lines above the pole, an observation which has since lead to such important results in connection not only with solar and stellar, but with terrestrial spectroscopy. The additions conclude with a very clear and succinct account of our knowledge of the movements of the gaseous masses on the surface of the sun, and the means of measuring their rapidity and direction. The nature of the spectroscopic phenomena of sun-spots is also described, but somewhat briefly. The added portion is illustrated with twelve woodcuts.

Mr. M'Leod's hand is again visible in the chapter relating to atomicity, where he has added in notes several important points in modern chemical theory, which had not been sufficiently explained in the original work of Dr. Miller; and we also notice in the body of the book a short explanation of the graphic and symbolical formulæ now so much used in explaining chemical facts to the student. We most cordially welcome this new and improved edition of an old friend, and congratulate the present editor on the share he has had in producing it.

R. J. F.

The A B C of Chemistry. By Mrs. R. B. Taylor. Edited by W. Mattieu Williams, F.R.A.S., F.C.S. (London: Simpkin, Marshall, and Co., 1873.)

THIS little book is intended apparently for the use of very young children. The attempt to explain the nature of the elements by analogy with the letters of the alphabet is somewhat obscure, though it would perhaps be difficult to find a different method. The book is divided into lessons, and each lesson followed by questions which are, on the whole, well selected. The same cannot, however, be said of the experiments at the end of the book, which all smack strongly of the "conjuring trick." We cannot coincide with the editor in recommending the book to artisans and business men, who, we think, might attempt something a little more advanced, even as a first book. For those, however, who wish to teach children chemistry, it will no doubt be useful.

Third Annual Report of the Wellington College Natural History Society, December 1870 *to December* 1872. (Wellington College: George Bishop, 1873).

IT is disappointing that the first words of this report, as in the case of the Rugby Society which we noticed recently, should be a confession of partial failure: "Natural History," the Preface begins by telling us, "does not flourish at Wellington College . . . The chief reason undoubtedly is, that during the past two years the older Fellows—and in particular the Sixth Form—have ignored the existence of the Society altogether." Judging from what is said at p. 36, the apathy of the older members of the school is owing to some antagonism which exists between the Natural History Society and the Debating Society attached to the school. But, with Mr. Penny, we

cannot see that there is any reason why the two societies should be in the slightest degree antagonistic. On the contrary, they might be mutually helpful, both having ultimately the same end in view—to teach the boys to examine, think, and act for themselves. Of course it ought to be remembered what a great innovation a society like that of Wellington College is on the traditional methods of instruction belonging to a school. The work is entirely voluntary, not clearly defined, as in the regular task-work of the school; and the only rewards held out, rewards which it is difficult to get the traditional school-boy to understand and appreciate, are, besides the direct acquisition of knowledge and the pleasure attending it, development of the power of observation, keenness of insight, and general intellectual vigour. A debating society, with all its undoubted advantages, is apt to become a nursery of boyish vanity; the reward of successful speaking is immediate and very sweet to a tyro, and can be obtained without much labour. The work of a Natural History Society involves much plodding patience, with very little glory to follow; the rewards are intangible, invisible, especially to the boys themselves, and it will take the training of a few generations to teach boyish human nature to love knowledge for its own sake. One of the most valuable means to accomplish this purpose in a school is a society like that of Wellington College, and therefore we would counsel those who are anxious for its prosperity not to be discouraged, but to work on so long as they can get any boys to work with them, using all possible means to insure success. We hope the merely local obstacles will be overcome, and that the next report will have a more lightsome beginning; also that it will contain many papers by the boys themselves, nearly the whole of the papers in the present report being by Mr. Penny and Mr. Lambert, and not one by a boy, though we are glad to see that some papers by boys were read at the meetings. The Rev. C. W. Penny, president of the Society, deserves the greatest credit for the interest he displays in the Society, and the amount of work he does to help on the objects for which it is established. A large number of the papers, full of instruction and interest even to boys, are by him; his predecessor in the presidentship, Mr. Lambert, has also contributed much to make the meetings of the Society attractive and instructive. Appended to the report are pretty full botanical, zoological, and entomological lists.

Familiar History of British Fishes. By Frank Buckland, Inspector of Salmon Fisheries of England and Wales, Corresponding Member of the "Deutscher Fischerei Verein," &c. &c. (London Society for Promoting Christian Knowledge.)

THIS is a new edition of the above work, Mr. Buckland having found it necessary, he says, almost to re-write the book. It may be described as a free-and-easy gossip about fishes, the book being largely made up of extracts from all quarters, *Land and Water* especially being very fruitful in material. As might be expected, Chapter xv., treating of *Salmonidæ*, and occupying upwards of 100 pages, a fourth part of the volume, is the most original and valuable. The chapter will be found useful to all who take an interest in the rearing and preservation of salmon. The numerous illustrations are very fairly executed, and the general reader will find the book entertaining and informing.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

Endowment of Research

Direct and Indirect Endowment

I SHOULD like to make one or two remarks on Prof. Flower's letter in your last number.

He modestly suggests that his views respecting the endowment of research unencumbered with teaching, or as he felicitously calls it, the *direct endowment of research*, may be considered by members of the Association for the Organisation of Academical Study as "heretical." I venture to think that he is orthodox on the main theoretical position that, *in the long run*, research must be endowed directly as well as indirectly (by the subsidy of teaching professors) and with an *equally* liberal hand. He is at issue with us only, if I take him rightly, as to the *time* when it will be desirable or possible to make a claim for such direct endowment. We contend that *now is the only time* for making such a claim, and for a reason which I will give presently. Mr. Flower, on the contrary, says that while *indirect* endowment of research, by raising the salaries of teachers, may be carried out at once with less opposition from old prejudices, "the far more difficult question will follow more appropriately and [the endowment] be carried out more efficiently when the body of educated scientific men in the country is larger than it is now, and the public generally, especially those in high places, have more appreciation of the claims of Science for its own sake," *i.e.* in the more or less indefinite future.

In answer to this I would say:—

(1) The "public in high places," by which I suppose is meant Mr. Lowe, who make a conscience of Political Economy, appear to appreciate the fact that the support of an useful and necessary but essentially unremunerative employment like research, out of public money is economically a sound investment; whilst the subsidy of a remunerative employment like teaching, out of public funds, though perhaps unavoidable, is nevertheless, economically speaking, an unsound one. We have no fear of Mr. Lowe's opposition.

(2) If by "the opposition of old prejudices" is intended the attitude of the Conservative party towards the claims of knowledge, I would call Mr. Flower's attention to the fact that some of the warmest supporters of "direct" endowment are political Conservatives. It is, indeed, one of the soundest elements in the Conservative consciousness, the distrust of immature generalisations resting upon insufficient inquiry; and the suspicion that, if we insist too much upon exposition, and throw the weight of our endowments into that, and if we make it every man's duty to be continually expounding, instead of insisting upon research and throwing the weight of our endowments into study, the heads of the rising generation run the risk of being inflated with immature and windy generalisations. Depend upon it, the Conservatives are prepared for keeping the endowments of our colleges for the support of that lifelong and uninterrupted study for which the founders originally intended them.

(3) Thirdly, Mr. Flower desires to wait till the demand for these supports of knowledge is much increased, and the body of scientific men wanting them is larger than it is now. But has he ever asked himself whether it is likely, that when this millennium of expectancy arrives, there will still be any university or college endowments undistributed, out of which this increased demand is to be satisfied? If Reformers of our old Institutions content themselves with sketching merely a teaching organisation on the German model, and with asking to have that amply endowed, and take no thought for the morrow when this larger body of trained investigators shall have come miraculously into existence—and I think this would be a real miracle, the emergence of a set of phenomena for which the conditions do not previously exist—if, I say, they are afraid of asking *now* to have a large fund gradually put in reserve, to be gradually drawn upon as the occasion arises, for the support of study and of those engaged in it—does Mr. Flower imagine that the remainder of the College endowments which are not taken up by the teaching establishment upon the German model, will be allowed to lie dead? That no claim will be put in for them by the county towns for the erection of more teaching establish-

ments, or for the support of the lectures to ladies, or as Mr. Walter Morrison desires, for the improvement of the incomes of village schoolmasters?

Assuredly all these claims, and more, will be put in for the residue of the funds—and I think it will be more than half—which will remain unemployed when we have pulled down our old Universities and set up our German teaching establishments in their stead. And shall we be able to offer any resistance to such demands, unless we can come forward *now* with the courage of our opinions, and present the whole of our scheme for a scientific as well as a teaching organisation, the former on a no less complete scale than the latter, instead of keeping half of our scheme, and the more important half of it, in our pockets? Mr. Flower will remember the old lines:—

> "When land is gone and money spent
> Then learning is most excellent."

In conclusion, I would refer for a moment to Mr. Flower's fifth paragraph, in which he seems to say that the interruption of research and study by teaching work or by official duties, is rather an assistance to them. As this statement is very often made, but always without the addition of any reasons for the opinion, I would respectfully ask Mr. Flower to let us know why an interrupted employment is more likely to prosper than a continuous one? what is the precise advantage of distracting intellectual force from the work it has to accomplish? and why the members of the Government, or, say, the jury in the Tichborne case, should not also be compelled to deliver at least one course of lectures during the London season?

July 25 C. E. APPLETON

Method of Endowment

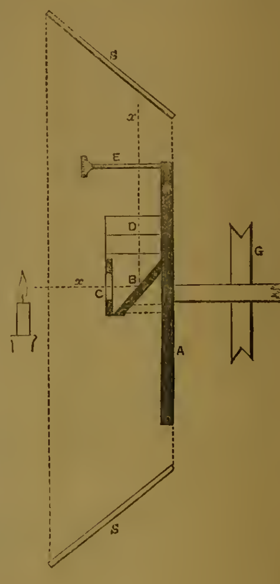
I HAVE read with much interest the three articles which have appeared in NATURE under the above title. The author of these articles has not as yet indicated the manner in which the object which he proposes is, in relation to the Universities, to be attained. He may intend to do this hereafter; but as the absence of any really practical scheme has been mentioned in the public journals as an objection in the way of such endowment as that proposed, I may perhaps be permitted to offer one or two suggestions on the matter. First, it appears certainly desirable that the Fellowships at the Universities should not be abolished, but that the conditions of their tenure should be changed. Scholarships of considerable value, and tenable for a limited number of years, might still be awarded after strict examination; but the Fellowships should be reserved exclusively for the recognition of a capacity for original research, proved by the publication of memoirs, or otherwise. Under such a system there would be little need for an Order of Intellectual Merit. The title of "University Fellow" might well suffice. I have used the expression "University Fellow," for though it would still be desirable that a certain proportion of the Fellows should be required to reside at the several colleges, yet it would probably be considered preferable that the power of election should be transferred from the colleges to a University Council. Such a Council would have to discharge a function similar to that annually performed by the Council of the Royal Society. To prevent favouritism and nepotism, it would be requisite that the names of all candidates should be published, together with the grounds on which each bases his candidature. Similarly the names of the selected candidates should be published, together with the reasons by which the Council have been influenced in their selection. But, it will probably be said, supposing that the Council have in their selection exercised a wise and unbiassed judgment, what is there to prevent the Fellowships from degenerating into mere sinecures? How is the continuance of original research to be secured? Probably there would be, in this respect, little danger in the case of those who have already proved their capacity for original work. But if it be contended that the danger is real, it would not be difficult to provide against it by granting Fellowships, not for life, but for ten or fifteen years, and by renewing them, on the expiry of the original term, only to those who have given strict proof of the continuance of their researches, making exception, of course, in the case of persons disqualified from work either by age or disease.

Such a scheme as that I have suggested would, I venture to think, be both practical and useful, though many matters of detail would still remain to be considered.

July 24 M. A.

Mechanical Combination of Colours

As you have kindly requested me to give a short account in NATURE of the instrument I designed to illustrate the "combination of colours," I have much pleasure in complying with your request. The instrument was designed to show the colour that resulted from the mixture of all or any of the colours of the spectrum given by any light. The construction is as follows:—



To the centre of a disc, A, which can be caused to revolve by the wheel G, a plain mirror, B, is fixed at an angle of 45° to the surface of the disc. In front of the mirror is placed a prism, D. At the edge of the disc there are placed different slides, E, for cutting off any particular rays; also, above the mirror, is a small slit cut in a piece of brass, C, to admit the ray under examination.

$x\,x$ is a ray of light, which passing through the slit C, is deflected at right angles by the mirror B through the prism D, and is then received in the form of a spectrum upon the screen S S. As soon as the wheel G is set in motion the spectrum also moves round the conical screen S S, and when a certain velocity is arrived at, the colours combine and form the original coloured light which is entering at the slit C. In the same way, by using the slides, any two or more colours may be combined to form the resultant colour.

FREDERICK J. SMITH

On seeing the Red Flames on the Sun's Limb with a Common Telescope

ON observing the partial eclipse of the sun on Dec. 22, 1870, it occurred to me whether it might not be possible to see the red flames on the sun's limb without waiting for a total solar eclipse, or whether it was possible to make an artificial eclipse sufficiently perfect to admit of the red flames being seen. Accordingly I cut out several circular discs of thin brass (blackened on both sides), leaving three arms projecting from the periphery of each of such length that when the ends were bent they should slide into the tube of the eye-piece. I placed one such disc in the eye-tube as near to the field lens as possible to avoid its getting hot; but here a difficulty presented itself which I had not foreseen,—the disc was a trifle too large, and it shut out the sun altogether. I put in a smaller one which admitted too much of the sun's light. I afterwards tried several, and it required a considerable amount of filing and scraping to produce one just the right size to cover the sun's disc and no more; especially as the least jarring or vibration of the telescope would cause the edge of the sun to be seen first on one side and then on the other. After several trials at different times I succeeded on January 16, 1872, in seeing on the south-western limb a red flame. It appeared rather wider at the top than the bottom

with a smaller one growing out from the bottom or root close to the sun's limb. There was another tongue of flame a little to the right, which appeared to be detached from the larger flame and also from the sun's limb.

On September 20, 1872, I saw a red flame which went up a little distance from the sun's limb and then divided in three. Close to this, on the edge of the sun's disc, was a group of nine small spots, and a large space was covered with faculæ. The flame—which was of a deep red colour—did not appear to be projected against the sky, but upon a very delicate purple background.

No coloured glass was used in either of these observations, but a sheet of letter paper was held between the eye and the telescope which was removed the instant the sun was brought into the centre of the field of view. R. LANGDON

The Huemul

IN the number of NATURE for July 24, p. 253, I see it is stated that "the Chilian Exploring Expedition has discovered a specimen of the Huemul, an animal that has been altogether lost sight of."

The late Earl of Derby received a female specimen of this animal from Port Famine, in the Straits of Magellan, described and figured by me in the Proc. Zool. Soc. 1849, p. 64, t. xii., as *Cervus leucotis*, which is now in the Derby Museum at Liverpool. Mr. Bates has sent to the British Museum a male and female of the Huemul, which were obtained by Don Enrique Simpson in a valley of the Cordilleras, lat. 46 S. These specimens have been described, the horns of the male figured, and the history of the animal given in detail by me, under the name of *Huamela leucotis*, in the Ann. and Mag. Nat. Hist. 1872, x. p. 445; 1873, xi. p. 214, and p. 308.

The animal, like all the American deer, differs from the stags of the Old World in having no tarsal gland.

British Museum, July 24 J. E. GRAY

Colour of the Emerald, &c.

IN the valuable and important paper given on this subject in NATURE (July 24), the writer has not made it quite clear what kind of emerald was experimented on.

Taken in conjunction with the beryl, it may be assumed that reference is intended to the green beryl, a silicate of alumina and glucina, commonly called emerald, from its colour; but the name of emerald is also applied to green varieties of corundum, which is crystalline alumina.

It would be interesting to understand fully the distinction of colour constituents.

July 25 A. H.

Parasites of the House Fly

SOME of your readers may not be aware that the common house fly is at this time frequently found with from one to twenty parasites on its body. To such I recommend the observation of them as an interesting microscopical study. They are usually on the under part of the fly and can be seen with an ordinary lens of high power. A. R.

Regent Street, July 23

Bees and Aphides

IN his interesting communication respecting the relations supposed to exist between *Trigona* and *Membracis*, Dr. H. Müller appears to have overlooked the Abbé Boisier's observation (Kirby and Spence, "Introduction to Entomology," 7th edition, p. 384) that hive-bees will collect the honey-dew excreted by Aphides. I have also observed the same habit in humble-bees.

Kilderry, Co. Donegal W. E. HART

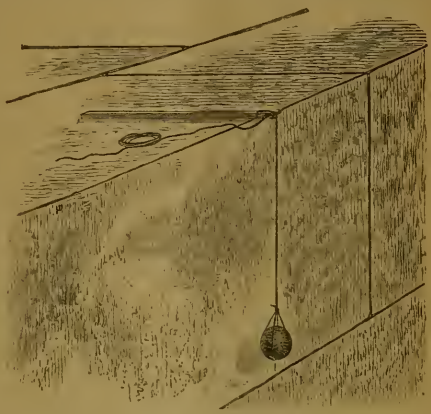
Flycatcher's Nest

SOME flycatchers have built their nest *inside* a temporary shed erected for the masons at present employed upon the rebuilding of Llanfrechfa Church. The nest is now full of young ones, and the old birds fly in and out of the shed with perfect confidence, carrying food to them, and quite regardless of the carving and sawing going on close to them.

July 16 ELIZABETH H. MITCHELL

Relics of the Pyramids

GLANCING over a number of your periodical I find depicted (vol. vii. p. 147) a grey granite ball, recently discovered in the Great Pyramid, and surmised to be an ancient Egyptian weight. It does not seem to have struck the author of the article that this ball could be anything else than a standard weight, but the description he gives leads me to assign to it quite a different use.



I believe it to be a naturally formed granite pebble, selected on account of its nearly spherical form, for a mason's "plumb-bob." The small white spots of lime found on the ball were probably the result of its impact against the narrow cement joints whilst the masonry was in progress and the mortar not yet set.

The bronze hook and cedar rod may have formed part of the same tool, which possibly resembled the accompanying sketch.

Mangalore, June 20 E. H. PRINGLE

FISH DISTINGUISHED BY THEIR ACTION

AS the trained eye of a constant resident in the country enables him to recognise the various species of birds that cross his path by their flight, irrespective of their form and colour, so the observer of fish as they wander at will in the tanks of a large aquarium soon learns to invest them with an additional marked individuality imparted by their mode of action. In some instances these distinctive characters are instructive, as illustrating the varied mechanical principles on which locomotion is effected, while in others they are highly valuable as affording accessory means of discriminating the zoological affinities of the different races and species.

Commencing with the Plagiostomous order, we find in the two primary sub-groups, including respectively the Sharks and Rays, that progression is effected on very distinct principles. With the *Selachoidea*, or shark tribe, the fish move by the even, powerful swaying from side to side of the largely developed and unsymmetrical caudal fin and whole posterior part of the body, the other fins remaining quiescent and being merely subservient as balancers. Descending to the species we find again that each form exhibits a peculiarity of action distinct from its congeners, and one which readily enables us to discriminate between them. Thus in the Smooth Hound, *Mustelus*, the pectoral fins are so largely developed that their balancing powers are highly augmented; comparatively slow motion of the caudal extremity suffices to propel the fish through the water, and the whole body being flexible, it pro-

gresses with a measured grace of action surpassed by no other species of its tribe. In the Picked Dogfish, *Acanthias*, the general contour of the body is very similar to that of the last species, but the pectorals being much smaller, more rapid action of the caudal extremity is requisite for supporting it in the water, and to this has to be added a great rigidity of the anterior half of the vertebral column, causing the fish to swerve from side to side with each stroke of the tail, the same cause preventing it also from turning corners with ease and rapidity, and altogether imparting to it a want of grace of action compared with that of other members of its tribe. For the foregoing reason this species requires a tank of larger size for its preservation in good health than other Dogfish, as if confined within the boundaries of a small one, it beats its head against the sides and rockwork to such an extent, that the cartilage of the skull is frequently exposed to view. In the Spotted Dogfish, *Scyllium*, the whole body is more elastic even than in *Mustelus*, a character admirably fitting it for its ground-loving habits, and enabling it to explore, and adapt itself to every sinuosity of the ground while hunting for its prey. When swimming in open water, it is distinguished by a more rapid action and swifter progress than *Mustelus*, though at the same time the greater amount of force expended in its movements deprives it of the peculiar grace associated with that species.

One anomalous form standing as it were between the Sharks and Rays, the Monk, or Angel fish, *Rhina squatina*, affords in its locomotive characters an interesting link further indicating its close affinity rather with the former than the latter group. The habits of this fish are essentially nocturnal, and throughout the daytime it usually reclines sluggishly at the bottom of its tank. Its depressed body and broadly expanded pectoral fins, resemble those of a Ray more than a Shark, and like the former fish it seeks concealment by burying itself beneath the sand or shingle, excavating a hole with the shovel-like action of these broad fins, and thus waits in ambush for passing prey. Immediately the Monk fish rises above the surface of the ground, its true affinities become apparent, progression being effected entirely by the lateral action of the caudal extremity, as in the Sharks, though in a more slow and clumsy manner. The lateral position of the gill openings in this fish forms its chief shark-like anatomical character, and to this has to be added its viviparous habits.

In the Batoidea, or Ray tribe, onward motion is accomplished by a singular, even, and wing-like action of the broad pectoral fins, the attenuated caudal extremity remaining perfectly quiescent, and serving only to preserve the fishes' equilibrium. Swimming towards the surface of the water, these fish present a most remarkable bird-like aspect, their large flapping fins reminding the observer of the flight of the heron or some other unwieldy representative of the Grallian order, while the slender tail dependent in the rear suggests the characteristic mode in which those birds hold their long legs, while pursuing their course through the more subtle medium which they inhabit.

Proceeding to the Teleostean group, we find the means by which the same organs are made subservient to the faculty of locomotion, still more highly diversified; space, however, will only admit of a few selections.

In the Gurnards, *Trigla*, during rapid movement, all the fins are pressed closely against the body, the broad wing-like pectorals being shut up like a fan, while the fish is propelled swiftly through the water by the vigorous undulations of the tail; when the fish moves leisurely the pectorals are opened to their full extent, acting as balances. In many species, such as the Striated Gurnard, *T. lineata*, these fins are brilliantly coloured, reminding the observer, especially when regarding them from above, of gorgeous tropical butterflies, gliding along with the smooth action characteristic of the Vanessa tribe. Yet a third property of motion is possessed by these remarkable fish. Settling on the ground at the bottom of the water, they are capable of literally walking over it by means of the three free rays of the pectoral fins, which are situated a little in advance of the others, and are curved and especially thickened, to adapt them for their anomalous office.

The Gemmeous Dragonet, *Callionymus lyra*, a small and beautiful fish somewhat resembling the Gurnards in outward appearance, is distinguished by an essentially different mode of progression. The habits of this species are rather sluggish; it spends much time reclining on the ground, occasionally moving for short distances just above its surface, by the flitting action of the delicate pectoral fins. On ascending towards the top of the water, its swimming capacities are shown to be very limited, being restricted to the weak vibrations of the pair of fins above mentioned, and which impart to it a peculiar jerky action. The male in this species is recognised by the extraordinary length of the first ray of the anterior dorsal fin, which is raised and depressed at pleasure like the latteen sail of a Mediterranean fishing yawl. This singular appendage appears, from my own observations of the species in confinement, to be subservient to the same end as the wattles, crests, and other abnormal adjuncts of the male in the Gallinaceous birds—for the purpose of fascinating their mates; to this is added a similar heightening of the colour, which is carried to such an extent in this fish, that the two sexes were long regarded and described as separate species, under the respective titles of *Callionymus lyra* and *dracunculus*.

In the Pipe-fish and Sea-Horses, *Syngnathus* and *Hippocampus*, representatives of the Lophobranchii, the organs of locomotion are reduced to their minimum, being often restricted, in the former genus, to a single median dorsal fin, and being at the most supplemented by a pair of diminutive pectorals and a rudimentary caudal. In all cases this dorsal fin is the chief propelling instrument, and in motion, rapidly undulating from end to end, illustrates the action of the Archimedian screw, driving the fish through the water on the same principle. Dr. J. E. Gray was the first to point out this remarkable peculiarity, in the case of *Syngnathus*, from observing these fish in the Aquarium at the Zoological Gardens. In both *Syngnathus* and *Hippocampus* the animal usually assumes a vertical position while progressing through the water.

The John Dorée, *Zeus faber*, affords us an example of the same principle noticed in the Syngnathidæ, applied to the purposes of locomotion, though to a still more remarkable and extensive degree.

One of these singular looking fish added to the Brighton tanks about two months since, has continued in perfect health up to the present time; and although of shy and retiring habits, has already yielded many points of interest in connection with its life history. The ordinary position assumed by this fish is the neighbourhood of some projecting rock near the bottom of its tank, and against which it sometimes inclines in a leaning posture, remaining motionless for hours together. Its ordinary progress from place to place is remarkably slow, and it is only when on rare occasions it rises high in the water, that the beautiful mechanism that guides its movements can be appreciated. It may then be seen that the only organs called into action are the narrow and delicate membranes of the posterior dorsal and anal fins, each of which vibrates in a similar manner to the single dorsal of the pipefish; the long filamentous first dorsal, pectorals, ventrals, and caudal fins meanwhile remaining perfectly motionless. Thus this wary fish, with an almost imperceptible action, silently and stealthily advances upon its intended prey, engulphing it in its cavernous mouth almost before the hapless victim is aware of its enemy's approach.

W. SAVILLE KENT

THE ORIGIN OF NERVE FORCE

TO any one taking a general view of the present position of physiology, there are few things more striking than the deficiency of our knowledge respecting the source of the current which traverses the nervous system, and is brought into play through the instrumentality of its various parts. That the current itself is electricity in some form or another, is almost universally acknowledged, but in what part of the body it originates, or from what store of energy it is derived, is more than most have attempted to answer. The question is made more difficult than it would otherwise be, from the fact that in all those animals which exhibit external electrical phenomena to any extent, such as the Torpedo and Gymnotus, there are large and elaborate special organs for the development of the shocks they produce, but no similar mechanicism, and nothing approaching to it, can be detected in man or other animals, whereby an electrical current or charge might originate. The brain and the various ganglia are often compared to the batteries of a system of electric telegraph, but how they would act if they were such, it is almost impossible to explain.

Direct evidence, therefore, failing to give a satisfactory solution of the problem as to whence nerve force originates, it is necessary to appeal to the indirect in endeavouring to obtain an answer. The hypothesis of "the survival of the fittest" evidently presupposes that after the struggle for existence has lasted a certain time, the individuals which remain, economise to the utmost all the forces at their disposal, because the more perfect use that a living being can make of the limited forces at its command, the easier will it be for it to continue to live. The Rev. Samuel Haughton from the resulting very strongly marked economy of the animal mechanicism, has deduced the principle termed by him that of "least action in nature." The generalness of this principle makes it necessary, if there is evidence of the existence of any store of energy in the living body apparently unemployed, to endeavour to find whether its effects have not been overlooked, or included with those of some other force; and if, at the same time, a force is at work whose origin is unknown, to try and prove whether the two are in any way related to one another. As shown above, there is a force which is in continuous action, with an unexplained origin; the question then resolves itself into whether there is a source of energy in the living body, whose effects have not been explained, and if so, can it on any known or probable grounds, be considered competent to give rise to the nerve current? An endeavour will now be made to show that both parts of the question may be answered in the affirmative; in other words, that there is an available source of energy, as yet unrecognised, of which the function is therefore not yet explained, and which is quite capable of giving rise to the nerve current.

This physiologically new source of energy is *the differences of temperature between the interior and surface of the living body*. Those who are unacquainted with the principles of the modern doctrines of thermo-dynamics, will readily perceive that a difference of temperature in two bodies is a source of power, when they consider that a low-pressure steam engine depends, for its power of doing work, on the difference of temperature between its boiler and condenser; and that a current may be maintained through a copper wire, if it is connected with a thermo-electric battery of which the two ends are kept at different temperatures. In what are termed hot-blooded animals, that is, in mammals and birds, the difference of temperature between the surface and the interior is considerable under all natural circumstances, and in them there is a regulating action of the skin, by which they maintain a uniform internal temperature, always hotter than the surface, whatever that of the external medium may be. In the sluggish so-called cold-blooded animals, the temperature of the interior of the body is but slightly different from that of the air or water in which they live; that it must be higher is evident from the fact that destruction of tissue is continually going on in their bodies, which is always necessarily attended with the evolution of heat.

Such being the case, it is evident that in the difference of temperature between the surface and the interior of the living body there is an available source of energy, which is almost certainly employed advantageously throughout the whole animal kingdom; and what is more, it may reasonably be supposed to be that which gives rise to the electrical nerve current, as only one assumption is involved, and that not an improbable one, it being that a thermo-electric current is capable of being generated between soft tissues of different composition or structure. Physicists will be able to decide this question experimentally, and if they do so, they will do a service to physiology.

For the distribution of a current so generated, the construction of the nervous system is perfectly suited. Two sets of conductors are necessary, the one to carry the currents from the skin to the central organ, which arranges the direction that they must take, and the other to send them on to their destination; these are to be found in the afferent and efferent nerves. As in the telegraph system, no return conductor is necessary; for as the ends of the wires are put into connection with the earth, by which they are able to communicate, so the terminations of the nerves in the skin, muscle-corpuscles and otherwise where they lose their insulated coverings, place the extremities of the afferent and efferent nerves in communication through the intervention of the mass of body tissue. The brain and minor ganglia would then act like greater and lesser offices for the reception and transmission of currents in the required directions, being in fact the commutators of the system.

There are several of the most important phenomena exhibited by the nervous system which are very satisfactorily explained on the above hypothesis. For instance, in cold weather the impulse to action is much more powerfully felt, than in summer when the air is hot, and therefore the temperature of the surface is higher. It is well known that it is impossible to remain for more than a very short time in a hot water-bath, of which the temperature is as high as, or a little higher than, that of the body, on account of the faintness which is sure to come on, and this may be reasonably supposed to be the result of the cessation of the nerve current, which is consequent on the temperature of the surface of the body becoming the same as that of the interior. This faintness is immediately recovered from by the application of a cold douche. When great muscular exertion has to be sustained, as in running or rowing, it is always necessary to have the clothes very thin, and it is felt during the time that it is necessary for the continuance of the effort, that the surface of the body must be kept cool.

As the termination of the nerves in the skin must correspond, on this hypothesis, with the cooled end of a thermo-electric battery, therefore the brain, which is very abundantly supplied with blood, and is the part of the body to which most of the nerves are directed, must be compared with the heated end; and as it is by the conversion of heat into electric current that the nerve force is developed, it is evident that heat must, to a certain extent, disappear as such in the brain, and that that organ must consequently be colder than the blood which enters it. This is exactly what Dr. John Davy observed in the case of the rabbits he experimented on, and his results have not been shown to be incorrect.

A paper on this subject by the present writer appeared in the June number of the *Journal of Anatomy and Physiology*.

A. H. GARROD

NOTES FROM THE "CHALLENGER"

V.

ON Wednesday, March 26, we sounded (Station 25) in lat. 19° 41′ N., long. 65° 7′ W., nearly 90 miles north of St. Thomas, in 3,875 fathoms. The bottom brought up in the hydra tube was reddish mud, containing, however, a considerable quantity of carbonate of lime. It is singular that the colour and composition of this mud were not uniform. The upper layer, that which had been forced farthest into the tube, was much redder than that which was nearest the mouth of the tube, and which had consequently come from a greater depth. I am inclined to attribute this to the

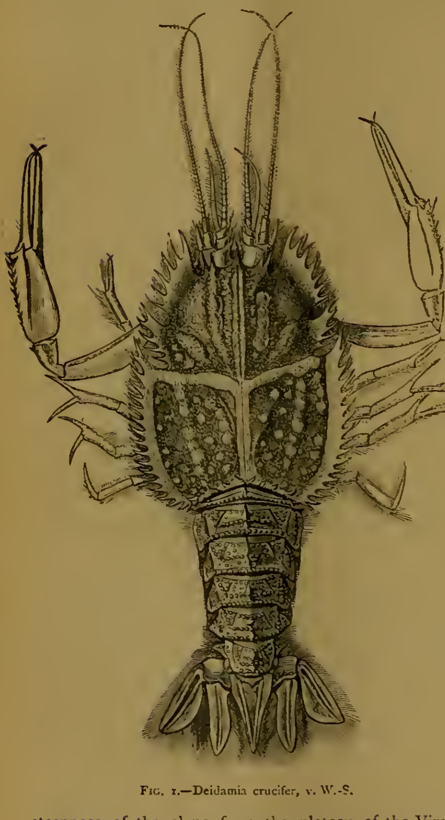


Fig. 1.—Deidamia crucifer, v. W.-S.

steepness of the slope from the plateau of the Virgin Islands. It is easy to conceive that, under the influence of currents varying from time to time in force and direction, the calcareous mud, the product of the disintegration of the coral reefs, may be washed down the incline in varying proportions.

Two thermometers were sent down in this sounding, and a slip water-bottle. The thermometers were unable to bear the extreme pressure, and both were broken. I have already (vol. viii. p. 109) in a former report described the circumstances connected with the loss of these two instruments. The water bottle appeared to have answered its purpose. Mr. Buchanan finds that the bottom water has a specific gravity slightly greater than usual at great depths, but not materially so. The amount of carbonic acid is somewhat in excess.

As this was the deepest sounding which we had taken, we were anxious to try whether the dredge would still prove serviceable. The small dredge was accordingly lowered with the usual bar and tangles, and from the centre of the bar a "hydra" sounding tube weighted with 4 cwt. was suspended about two fathoms behind the dredge. A two-inch rope was veered to 4 400 fathoms; a toggle was stopped on the rope 500 fathoms from the dredge, and when the dredge was well down two weights of one cwt. each were slipped down the rope to the toggle. We commenced heaving in about 1.30, and at 5 P.M. the dredge appeared, with a considerable quantity of reddish-grey ooze, mottled like the contents of the sounding-tube. The whiter portion effervesced freely with acids, the redder only slightly. The mud was carefully examined, but no animals were detected except a few small foraminifera, with calcareous tests, and some considerably larger of the arenaceous type. This dredging, therefore, only confirmed our previous conviction, that very extreme depths, while not inconsistent with the existence of animal life, are not favourable to its development. In the afternoon a series of temperatures were taken at intervals of 100 fathoms from the surface to 1,500. The temperature at the surface was 24°·5 C., and that at 1,500 2°·4 C. The curve constructed from this series indicates a very rapid and uniform fall of about 20 C. during the first 600 fathoms, and generally a distribution of temperature almost identical with that of some of the later stations on the section from Santa Cruz to Sombrero. In this way we pursued our course northwards under all plain sail.

On the following day we sounded in much shallower water—2,800 fathoms. The bottom was much of the same character, and on the 28th in 2,960 fathoms with a like result, but at our next sounding in 2,850 fathoms on the 29th, the calcareous element in the mud had almost entirely disappeared, and the contents of the tube seemed to be identical with the "red clay" which occupied so large a portion of our first section. The occurrence of this clay is a large and important phenomenon. In the section of the Atlantic, from the Canaries to the West Indies, it occupies about 1,900 miles, a distance twice as great as that occupied by the globigerina mud. What its lateral extension from that line may be, we do not know; but we now find that it extends more or less from over the greater part of the distance between St. Thomas and Bermudas. The nature and source of this deposit, and the causes of its peculiar distribution in the deeper parts of the ocean, are therefore questions of the highest interest.

On the 2nd of April, at a distance of 134 miles from Bermudas, a series of temperature soundings was taken at intervals of 20 fathoms from the surface to 300 fathoms.

The pilot came on board in the afternoon of April 4 and we passed through the narrows, the reefs which make, the navigation of this singular little group of islands so dangerous spreading round us in rich purple patches, contrasting with the vivid pale green of the channels of deeper water between them.

The evening was falling as we anchored in Grassy Bay and received our first impressions of Bermudas. On the Monday following we moved from Grassy Bay to the Camber, in the great Dockyard. We remained there till the 21st of April, and employed the interval in taking such a general survey of the natural beauty of the island as our time allowed.

As Bermudas, on account of its isolated position, its structure, and its peculiar conditions of temperature, presents many points of great interest, I will defer giving a

detailed account of it until some investigations which we have still in hand are completed.

We met at Bermudas with a singular confirmation and illustration of our view as to the organic origin of the "red clay" of the Atlantic sea-bed.

The Islands of Bermudas consist exclusively of limestone, in some places very compact and hard, almost crystalline; more usually soft and crumbling easily when first quarried, but hardening on exposure to the air. The limestone is very irregular in the direction of its dip. In amount, however, the dip seems never to exceed 30°. The beds are thrown about in a curious way, every quarry or road-cutting showing contortions of all kinds in the strata and every amount of irregularity consistent with uniformly low angle of dip. One would imagine at first sight that the islands exhibited, on a small scale, an epitome of the geological phenomena of a disturbed palæozoic district.

Lieut. (now General) Nelson, R.E., at that time a young man, stationed at Bermudas, communicated to the Geological Society of London on April 23, 1834, a very valuable paper on the geology of Bermudas, which was published in the fifth volume of the Transactions of the Society. Lieut. Nelson pointed out that the great proportion if not the whole of the Rocks of Bermudas are formed simply by the blowing up by the wind of the fine calcareous sand the product of the disintegration of the coral, shells, serpula-tubes, and the other constituents of the Bermudas reefs, that white sand which we found to extend at varying depths through a radius of about 20 miles round the island. The sand is washed in by the sea; it is then caught at certain exposed points by the prevailing winds, blown into sand-hills 40 to 50 ft. in height, which slowly move along, forming shoreward a glacis at the angle of repose of loose sand, on which lamina after lamina is deposited, overwhelming a large tract of country with its fields, gardens, and cottages, in a comparatively short time, and advancing until its progress is stopped by an opposing slope of sufficient height, or by the binding of the sand by vegetation. On these wind-blown beds of lime, aptly called by Lieut. Nelson, Æolian formations, which are originally formed at a considerable inclination, changes in the direction and force of the wind-floods of sub-tropical rain and other transitory and accidental causes produce with great rapidity all the appearances, denudation, unconformability, curving, folding, synclinal and anticlinal axes, &c., which are produced in real rocks, if I may use the expression, by combined aqueous and metamorphic action, extending over incalculable periods of time.

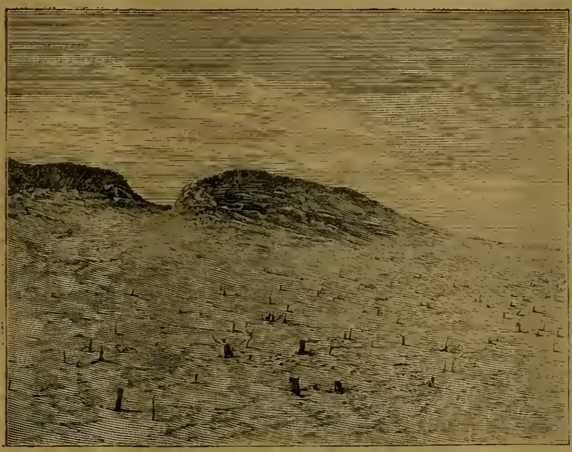

FIG. 2.—Rocks of Coral Sand in Bermudas in process of formation, showing Stratification, and the Stumps of Cedars which have been overwhelmed.

Rain-water contains a considerable quantity of free carbonic acid. Water thus charged dissolves the lime rapidly, and the solution of bicarbonate of lime percolating through the bed, loses a portion of its carbonic acid, and deposits a cement of carbonate of lime between the particles of the coral sand. This process is kept up not only by the surface rain but by the water of the sea, which, as we shall see, percolates through the porous stones of the islands. As evidence of the universality of this process, we have every crack and fissure of the rock filled with semi-crystalline stalagmite, and every here and there the rock is hollowed out into caves which in some places assume the proportions of magnificent caverns with lofty roofs, supported by huge stalagmitic columns, and fretted and enriched by curtains and fringes of stalactite.

One very striking thing about Bermudas is the total absence of running water. There is not a trace of a stream or pool, or even of a ditch. The rain, which often falls in great quantities, sinks through the soil at the spot where it falls as it might sink through a sieve. The islands are perfectly permeable to water horizontally as well as vertically, so that below the level of the sea the stone is saturated, or filled with salt water. The fresh water lakes and wells, of which there are many, are thus merely catches of fresh water lying upon the surface of salt water, and they are nearly all slightly brackish, and those near the sea rise and fall perceptibly with the tide.

WYVILLE THOMSON

ON THE SCIENCE OF WEIGHING AND MEASURING, AND THE STANDARDS OF WEIGHT AND MEASURE

I.

DURING the last few years public attention has been frequently drawn to the subject of our national weights and measures. The administrative and social questions of the improvement of our existing system, and of the proposed introduction into this country of the decimal metric system—first established in France, and now being generally adopted on the Continent of Europe, and indeed extending to the other quarters of the world—have formed the subjects of debate in every Session of Parliament, and are still awaiting solution. The scientific questions involved in the use of weights and measures have for a much longer period engaged the attention of many of our most eminent men of Science, several of whom have been members of the various Standards Commissions from time to time appointed by the British Government. These questions are also at the present time the objects of investigation and deliberation by the large body of scientific men from all civilised countries, who compose the International Metric Commission at Paris. It may, therefore, be useful to bring together and place before the public the several points involved in the science of weighing and measuring, and to give some account of our standards of weight and measure, as well as to describe in some detail the scientific construction of our existing imperial standard yard, and pound. No sufficient means have hitherto been adopted for making the general public acquainted with this part of the subject, although they are directly interested in it, the information hitherto published respecting it having been confined to a few papers in the "Philosophical Transactions," and to reports of the several Standards Commissions, and other Parliamentary Returns. Of these papers the most important are those on the construction of the imperial standard pound, by Prof. W. H. Miller, in "Phil. Trans.," 1856, and on the construction of the new imperial standard of length, by the Astronomer Royal, now Sir G. B. Airy, K.C.B., in 1857. In the following treatment of the subject use will be made of these papers, as well as of other authoritative works relating to weights and measures.

The science of weighing and measuring comprehends the following points :—

The scientific definition of weight and measure.

The authoritative establishment of fundamental units of weight and measure of length and the construction of their material representatives as primary standards, in relation to which all numerical amounts of weight and measure are to be expressed.

The establishment of determinate aliquot parts and multiples of the primary units of weight and measure, and of other units derived from them, such as the unit of measure of capacity, &c.; and the construction and verification of their material representatives, as secondary standards, by comparison with which the accuracy of all weights and measures in ordinary use is to be determined.

The scientific methods of using standard and other weights and measures in which special accuracy is required, as well as auxiliary scientific instruments, such as balances, thermometers, barometers, micrometers, and other comparing apparatus.

The determination of the just results of weighing and measuring with these scientific instruments, after allowing for all indirect influences affecting the accuracy of the direct results of weighing and measuring; for instance, differences arising from the physical composition of bodies, variations of temperature and consequently of the expansion or contraction of the several substances, changes of condition in the medium in which the comparisons are made, &c., including also a computation of the probable errors of the final results.

The whole subject will therefore be treated under the following general heads :—

I. Definitions of weight and measure.
II. Standards of imperial weight and measure.

IV. The metric system.
V. Weighing and measuring instruments and their use.

I. *Definitions of Weight and Measure.*

Weight or *gravity* has been defined as the quality in physical bodies by which they tend towards the centre of the earth, in a line perpendicular to its surface; or it may be defined more generally as a property inherent in all bodies, by which they are drawn to some common point, called the centre of gravity, and with a velocity in proportion as they are more or less dense, and as the medium through which they pass is more or less rare.

In following out his discovery of the theory of universal attraction and gravitation, Sir Isaac Newton demonstrated, first, that the weights of all bodies at equal distances from the centre of the earth are directly proportional to the quantity of matter that each body contains; whence it follows that the weights of bodies have no dependence on their shapes or textures, and that all spaces are not equally full of matter. Up to the time of Newton the earth was considered to be spherical, but it was demonstrated theoretically by Newton, as well as by Huygens, that the earth must be flattened at the poles. Whence it was shown by Newton, secondly, that on different parts of the earth-surface, the weight of the same body is different, owing to the spheroidal figure of the earth, which causes the body on the surface to be nearer to the centre in going from the Equator towards the Poles; and that the increase of the weight is nearly in proportion to the versed sine of double the latitude, or, which is the same thing, to the square of the sine of the latitude. He assumed the weight at the Equator to that at the Pole to be in the proportion of 229 to 230, and consequently the whole increase of weight from the Equator to the Pole to be the 229th part of the weight at the Equator.

In accordance with the principle the discovery of which is ascribed to Archimedes, that all bodies immersed in a liquid suffer a loss of weight precisely equal to the weight of the liquid displaced, it was also demonstrated that a body immersed in any fluid specifically lighter than itself loses so much of its weight as is equal to the weight of a quantity of the fluid of the same bulk with itself. Hence a body loses more of its weight in a heavier fluid than in a lighter one, and therefore it weighs more in a lighter fluid than in a heavier one, for instance, more in air than in water.

The foregoing principles laid down by Newton are universally admitted as correct, with the exception of the numerical proportions of the weight of bodies at different parts of the earth's surface; for it is important to observe that Newton founded his calculation of the earth's ellipticity on the hypothesis of its being homogeneous, which is not the case; and hence he makes the equatorial diameter greater than the polar axis, as 230 is to 229. But from the numerous experiments since made with the pendulum at different parts of the earth, it has been found that the earth is not homogeneous, or composed of concentric strata of equal density, and that the ellipticity is not so great as Newton supposed.

The method of measuring the intensity of gravity on different parts of the terrestrial spheroid, by means of the seconds pendulum, is said to be due to Borda, as originally described in a Memoir inserted in vol. iii. of the *Base du Système Métrique*. From the results of Borda's experiments, made towards the close of the last century,

Laplace computed the ellipticity of the earth to be $\frac{1}{330}$, but later experiments and computations of other men of science concur in making it nearly $\frac{1}{300}$.

In the Philosophical Transactions of the Royal Society for 1818, Capt. Kater has stated the results of his pendulum experiments in London, and determined the length of the pendulum vibrating seconds, or completing one vibration in $\frac{1}{86400}$ part of a mean solar day, when measured in a vacuum at the mean level of the sea and at a temperature of 62° Fahr. to be 39·13842 inches of the Standard yard, which was legalised in 1824 as the Parliamentary Standard of length. The latitude of his place of observation in London was 51° 31′ 4″ N. He subsequently made a slight correction in this determination, making the length of the seconds pendulum to be 39·13929 inches, as shown in Phil. Trans. 1819, and this length, or rather 39·1393 inches, was declared to be the true length in the Standards Act of 1824.

It was, however, discovered by Bessel that the correction which had ordinarily been applied, and was applied by Kater, for reducing the vibrations of a pendulum, as observed in ordinary air, to vibrations in a vacuum, ought to be greatly increased. The experiments were consequently repeated by Capt. (now Sir Edward) Sabine, with special reference to the form of pendulum usually employed in England. In Phil. Trans. 1821, Sir Edward Sabine has shown as the results of his experiments on the acceleration of the pendulum in different latitudes, that the mean diminution of the force of gravity from the pole to the equator was 0·0055138, in other words, that a weight of 100 lbs. at the equator would be less by 0·55138 lb. at the pole; whilst the resulting mean ellipticity of the earth deduced from his pendulum observations, was $\frac{1}{313 \cdot 6}$. Sir Edward Sabine has also shown as the result of his experiments on the length of the seconds pendulum in Greenwich Observatory, that its length vibrating 86,400 seconds in the 24 hours, at the temperature of 62° F., and in a vacuum, was found to be 39·13734 inches.

In his paper on the Yard, the Pendulum, and the Metre, Sir J. Herschel has observed that the true measure of the earth's attraction (independent of centrifugal force arising from its rotation), is best to be derived from an ideal seconds-pendulum supposed to vibrate at the extremity of the earth's polar axis; and that the mean length of the polar or of the equatorial pendulum must be derived from the general result of observations of the lines of oscillation of one and the same invariable pendulum at a multitude of geographical stations in all accessible latitudes in both hemispheres; but that no two combinations agree in giving the same precise length, in consequence of the local deviations of the intensity of gravity, due to the nature of the soil or crust of the earth, and the configuration of the ground immediately beneath and around the places of observation. And further, that since the pendulum cannot be observed at sea, the whole sea-covered surface of the globe is of necessity excluded from furnishing its quota of observations to the final or mean conclusion. Water being on the average not more than one-third the weight of an equal bulk of land, such as the earth surface consists of, and only $\frac{2}{11}$ of the mean density of the globe, the force of gravity at the surface of the sea is less than at the sea-level on land by the attractive force of as much material taken at twice the specific gravity of water (or at $\frac{4}{11}$ that of the globe), as would be required to raise the bottom to the surface.

With regard to the determination of the earth's ellipticity, as shown by actual measurements of the dimensions of our globe, and the relative length of the equatorial diameter and the polar axis of the earth, the most recent determination is that by Major Clarke, as stated in his "Comparison of Standards of Length," published in 1866. This memoir has been declared by Sir J. F. M. Herschel, to be the most complete and comprehensive discussion yet received on the subject of the earth's figure, and to be held as the ultimatum of what scientific calculation is as yet enabled to exhibit as to its true dimensions and form.

Major Clarke's results were computed, not from pendulum experiments, but from the combination of all the separate measurements of arcs of meridians in Peru, France, Prussia, Russia, Cape of Good Hope, India, and in the United Kingdom. They are as follows:—

	Feet.	Inches.	Metres.	Metres according to Capt. Kater's equivalent.
Length of Polar axis.	41,706,858	500,482,296	12,712,136	12,712,020
Longer equatorial axis (long. 15° 34′ E.).....	41,853,700	502,244,400	12,756,588	12,756,470
Shorter equatorial axis (long. 105° 34′ E.)...	41,839,958	502,079,496	12,752,701	12,752.588
Length of meridian quadrant of Paris....	32,813,524	393,762,292	10,001,472	10,001,381
Length of minimum quadrant (long. 105° 34′ E.).................	32,808,772	393,704,064	10,000,024	9,999,953

In computing these equivalents, Major Clarke takes the metre at the temperature of 32° F. from his own measurements to be equal to 1·09362311 yard at 62°, that is to say to 3·28086933 ft., or to 39·37043196 in., instead of the more generally received determination by Capt. Kater of 39·37079 in. The metric length according to both these equivalents is here given.

From the determination of the earth's dimensions, it may be easily computed, that the earth's ellipticity in the longitude of Paris, is $\frac{1}{288}$, whilst its mean ellipticity in all longitudes is $\frac{1}{298}$.

Hence also the mean length of a degree of latitude in the longitude of Paris is $\frac{32,813.524 \cdot 38}{90} = 364,591$ ft., or 69·05 miles. The mean diameter of the earth is 41,800,173 ft., or $7216\frac{2}{3}$ miles, and its mean circumference 23,871 metres.

Thus not only each longitudinal meridian, but also the equator is slightly elliptical.

Sir H. James has shown in his preface to Major Clarke's paper that the longest meridian in 15° 34′ east longitude, nearly corresponds to the meridian in the eastern hemisphere which passes over the greatest quantity of land; and in the western hemisphere to that which passes over the greatest quantity of water, as it passes through the centre of the Pacific Ocean. The shortest meridian in 105° 34′ east longitude nearly corresponds to that which passes over the greatest quantity of land in Asia; and in the western hemisphere, and that which passes over the greatest quantity of land of North and South America.

The connection here shown to exist between the definition of weight and the measurement of the dimensions of our globe, leads naturally to the definition of the second principal head of the subject, viz. of measure.

Measure is generally understood to mean the determinations of a body with relation to a fixed standard unit, or the measure of extension; and it is in this sense that it will now be taken in discussing the "science of measuring." The measure of extension comprehends

The measure of length, or linear extension;
The measure of surface, or square measure;
The measure of volume, or solid or cubic measure;
The measure of capacity, or the cubical quantity contained in any vessel for measuring dry goods, liquids, or aëriform fluids.

All these measures of extension are based upon one fixed standard unit of length; and as all measures of length vary according to their temperature from expansion or contraction, the length of the standard must be fixed at a normal temperature.

Strictly speaking, measure includes weight, which is the measure of the gravitation of bodies towards the centre of gravity. And measures of capacity also are almost universally derived, not from their cubical dimensions, but from the weight of pure water contained in them under determinate conditions as to temperature and atmospheric pressure.

The measure of temperature is based upon the observed rate of linear expansion by heat of a body selected for this purpose, generally mercury, taking as constant units the temperature of melting snow or ice, and of water boiling under determinate atmospheric pressure.

In defining measure, it should be added that it is also applied to the measure, or (as it is termed) *admeasurement* of the tonnage of ships, being a determination of the weight a ship is capable of carrying, with relation to its measure of cubic capacity; to value in relation to a monetary unit; to time and duration in relation to the unit of a mean solar day or a second, its 86,400th part; to velocity, by combining the measure of extension with that of time or duration; to mechanical work, the unit of which is a horse power, as it is commonly termed, or more properly the power of raising 33,000 lbs. one foot in one minute, thus combining the measures of linear extension, weight, and time; to angles, the unit being a degree or the 360th part of a circle described from the point of junction of the two straight diverging lines forming the angle; &c. &c. It is not, however, proposed here to refer further to these measures or to the scientific questions connected with them.

The measure of volume, or bulk of a body, as compared with that of another body differing in volume but equal in weight, is shown by its density, and is also expressed in terms of a fixed standard unit. The densities of bodies are in the direct ratios of their masses, or quantity of matter, and in the inverse ratios of their volume.

The density of a body is defined to be the mass contained in a unit of volume, when referred to a uniform standard. The specific density is to be distinguished from its specific gravity, which shows its weight in relation to its volume, also when referred to a uniform standard. The specific gravity of a body is defined to be the *weight* of a unit of its volume.

The specific gravity of a body is the quotient of its density when divided by the density of that substance which is considered as unity. Pure water is generally adopted as such unity. But since both these densities vary with the temperature—because the same invariable quantity of matter which the body contains is always distributed over its whole volume, and this is variable with the temperature; so that, generally speaking (with some exceptions, pure water, for instance, at certain temperatures), the body, at a higher temperature, has less density than at a lower temperarure—we must fix a certain temperature at which the body, as well as the water, must be considered. It is not necessary that this fixed temperature should be the same for the body and the water, its choice for both being quite arbitrary.

For bodies the most convenient standard temperature for expressing their density seems to be that of one of the fixed points of the thermometer; and the temperature of melting ice or snow (32° F. or 0° C.) is generally adopted. For pure water, there is a maximum of density which occurs at nearly 39° F. or 4° C., and this maximum density of pure water is generally adopted as the unit of density.

The sign $\triangle$ prefixed to the symbol of any weight, with its numerical value following, denotes the ratio of the density of the weight at the temperature of melting snow to the maximum density of pure water.

The relation of the bulk or volume of a body to its weight is expressed both by its density and its specific gravity, these terms being often used indiscriminately. But the former term is more strictly applicable to solid bodies, and the latter to liquids and gases.

To ascertain the density of a body, it is requisite that its volume should be determined, as the density cannot be directly found. The actual volume may be determined—

1. Either by cubic measurement, when the form of the body admits of this measurement being actually made; but this occurs but rarely.

2. Or by ascertaining its specific gravity, from determining the difference of its weight when weighed in air and in water. This is the readiest and most accurate mode of determining both its volume and its density, but the immersion of a body in water is not always practicable, or it may be injurious to the body under experiment.

H. W. CHISHOLM

(To be continued.)

NOTES

AT the Meeting of the Paris Academy of Sciences, M. Ferdinand de Lesseps was elected an "Academicien libre" in the place of M. de Verneuil, deceased. M. de Lesseps obtained 33 votes; M. Breguet, 24; MM. du Moncel, Jacquemin, and Sedillot 1 each. M. de Lesseps thus obtained 2 votes beyond the absolute majority required to render an election valid, and was therefore declared elected. The number voting, 60, was large.

THE forty-first Annual Meeting of the British Medical Association will be held in King's College, London, on Tuesday, Wednesday, Thursday, and Friday, August 5th, 6th, 7th, and 8th. The President-elect is Sir William Fergusson, Bart., F.R.S. The following are the six sections into which the meeting will be divided, and in each section a very large number of papers is already entered to be read:—Section A, Medicine; B, Surgery; C, Obstetric Medicine; D, Public Medicine; E, Psychology; F, Physiology. The sections will meet in rooms of the College appropriated for the purpose, and the Annual Museum of objects of interest in connection with medicine, surgery, and their allied sciences will be arranged in the Library of the College. The President's address will be delivered at 3 P.M. on August 5, and in the evening the Lord Mayor will hold a reception at the Mansion House. The following public addresses will be delivered:—On August 6, an address on Medicine, by Prof. E. A. Parkes, M.D., F.R.S.; on August 7, an address on Surgery, by Prof. John Wood, F.R.S.; and on August 8, an address on Physiology, by Prof. Burdon Sanderson, F.R.S. The President and Council of the Royal College of Surgeons hold a reception on the evening of August 6, and several excursions have been arranged to take place during the meeting. Altogether, to judge from the programme, the meeting promises to be a very successful one.

THE Royal Archæological Institute commenced its annual session at Exeter, on Tuesday, when the Mayor and Corporation held a reception at noon. The President, the Earl of Devon, thereafter delivered his inaugural address on the advantages of the study of Archæology, and in the afternoon an excursion took place to Rougemont Castle. In the evening, again, the Mayor held a reception in the Albert Museum. The Sectional Meetings commenced yesterday, and several interesting excursions have been arranged. The Sections are, Antiquities, Architecture, and History. One of the most attractive accompaniments of the Exeter meeting is the formation of a temporary Museum and Portrait Gallery.

THE French Association for the Advancement of Science commences its second session at Lyons on August 21, the concluding meeting to be held on August 28. As was the case at Bordeaux, there will be General Meetings, Meetings of Sections or Groups, Scientific Excursions, and Public Lectures. A

large number of papers has already been entered to be read at the Sectional Meetings, by well-known scientific men, and several interesting excursions have been planned, including one to the famous pre-historic station at Solutré. So far, this year's meeting of the Association promises to be very successful. Immediately after the session of the Association is concluded, the Geological Society of France holds its annual meeting at Roanne.

Dr. Göppert, of Breslau, the veteran writer on the subject of fossil plants, is desirous of disposing of his immense collection, in securing which he has spent more than thirty years, and made it perhaps the finest in the world, embracing, as it does, type specimens of 94 different works and 400 minor essays, represented on about 1,000 plates. The number of specimens exceeds 11,000, and includes Sigillaria from sixteen to twenty feet in length, and other specimens of equal magnitude. There are also 200 specimens of different kinds of amber with their inclosed plants, and also a series of diamonds, with various objects included in them. In addition to the fossil objects there is also a very large collection of recent plants, which serves to illustrate the first-mentioned series, such as palms, tree-ferns, cycades, bamboo, algæ, sections of wood, fruits, seeds, &c. Numerous original drawings also accompany the collection, which add much to its value.

Mr. Smith gives some very interesting details in the *Daily Telegraph* of his excavations at Nimrod. We think, however, the main result of his expedition is to show the necessity of a more thorough and longer continued exploration of the ruins of Assyria than Mr. Smith has been able to give; and the sooner such an exploration is undertaken, the more fruitful are the results likely to be.

The *New York Herald* of the 17th inst. publishes a letter from Dr. Petermann, the eminent German geographer, to Dr. Strasnecky, the Secretary of the American Geographical Society. In it he says:—As at the departure of the expedition much stress was laid on its prospect of reaching the North Pole, the public at large, which has no idea of the difficulties surrounding the solution of geographical problems, might look upon it as a complete failure. It should not be made a reproach to Captain Hall that he held out such a prospect, for without it he would not probably have obtained either ship or money, or any other support. Placed in a similar condition, the same thing has happened to me and my friends in Germany, and it will always remain thus as long as the civilised Governments of the world devote their millions principally to the increase of their armies, and the scientific objects only figure in the Budget for the crumbs, and as long as people who are willing to add to the little knowledge we have of our own earth have to go begging for small contributions. To me the geographical results of the expedition appear of an extraordinary value. At any rate they are the highest that any vessel among the numerous expeditions of all nations to the North and South Poles have ever accomplished for many centuries. I shall speak of the subject at greater length in my next Arctic report (No. 80).

At the commencement of 1874, says the *Deutsche Zeitung*, one or two ships of the German navy are to be sent on a scientific mission to observe the transit of Venus. These vessels will have to submit their observations, which are to be extended to ocean currents and tides, to the hydrographic office of the German Admiralty.

The first three numbers of a work on indigenous and exotic Lepidoptera have been issued by Mr. Hermann Strecker, of Reading, Pennsylvania, U.S. the object of the author being principally to bring to the cognizance of the public the many new species from all parts of the world embraced in his very extensive cabinet. While the preference will be given to those from North America, he, unlike Mr. William H. Edwards, includes some species from other countries. The illustrations, which occupy one plate for each number, are all drawn, printed, and coloured by Mr. Strecker himself in the intervals of his daily labours, and the whole work is extremely creditable to him. The work is in quarto, and it is proposed to publish one number every two months, each with a single plate, crowded as fully as possible with figures. The enterprise is well worthy of commendation, and persons desirous of obtaining the work can do so by addressing Mr. Strecker, as above. A few copies only are printed, and the drawings then erased to make way for a new set.

Prof. Meek announces the existence of primordial species among the fossils collected by Dr. Hayden, in 1872, from near Gallatin City, Montana, U.S.—a very important geological fact. He has also found carboniferous fossils in various localities. Some of these are from the "divide" between Ross's Fork and Lincoln Valley, Montana, embracing many of the same species as occur in the noted Spurgen Hill locality, in Indiana, of the age of the St. Louis limestone.

At noon of July 8 Prof. Agassiz formally opened the Anderson School of Natural History on Penikese Island, thus bringing to a practical beginning the great idea of a summer school of natural science as first suggested by Prof. Shaler. Our readers are sufficiently familiar with the details of the circumstances which led to the establishment of this magnificent educational enterprise—first, the donation by Mr. John Anderson, of New York, of Penikese Island, one of the Elizabeth group, situated at the entrance of Buzzard's Bay, and valued at 100,000 dollars; then his endowment of it in the sum of 50,000 dollars to meet the current expenses; and subsequently the presentation to the professor by Mr. Galloupe, of Swampscot, of a yacht worth 20,000 dollars, for use in deep-sea dredgings and other explorations in connection with the school. In a circular Prof. Agassiz gives notice to the public that the island affords no accommodation to strangers, and that no guests can be received excepting those who have been accepted as members of the school. The limit of fifty has long since been made up, one-third of them being ladies, while more than a hundred have been rejected in consequence of the limitation. A caterer has been engaged, who will provide for the table, and keep the rooms in order. There is to be no charge whatever for tuition, and as the dormitories have been built at the expense of the fund, no rent will be charged beyond a percentage of the value of the bed-room furniture. The board is to be charged at cost. Should any persons desire to make collections of specimens to carry away with them, cans and alcohol will be furnished at cost to those who are not already provided.

The Russian astronomers have decided upon occupying twenty-four stations on the important occasion of observing the Transit of Venus. It is found that the weather will probably be highly favourable to astronomical observation at all the stations in Siberia and on the Pacific coast, as there is an average of only three cloudy days in the month of December in these parts of the Russian possessions. The extreme cold of November is well regarded as an almost insuperable hinderance to the proposed work. The following very complete outfit has been ordered for use on this occasion, viz., three heliometers and three photoheliographs, for use in measuring the position of the planet on its passage across the sun's disc; ten equatorials, for observing the apparent contacts of the limbs of the planet and sun by the use of the spectroscopic method, and for the determination of the same moments by observations with the filar micrometer; ten telescopes, for simply observing the instant of each contact; and besides these, there is for each station a complete outfit of clocks, chronometers, and instruments for determining the local

time. The observers are all to practise beforehand at the Imperial Central Observatory at Pultowa. The geographical positions of those stations at which the observations result successfully will be afterwards determined by a special geographical expedition by the Russian navy. To perfect this portion of the work, a line of telegraph will be built through Siberia to Nicolaevsk.

WE have received the programme for Session 1873-74 of the University of Durham College of Physical Science, at Newcastle-on-Tyne. It contains ample information as to the amount and kind of instruction to be obtained at the Newcastle College, and full details as to the arrangements, fees, examinations, exhibitions, and scholarships. There are three exhibitions of 15*l.* each to be awarded after examination in October, one scholarship, the T. Y. Hall scholarship, of 20*l*, yearly value, tenable for three years, and two scholarships offered by Mr. Hugh Taylor, consisting of the expense for maintenance and education at the Newcastle College, for two years: those last are for sons of overmen, deputies, or pitmen, who are engaged in coal mines in the counties of Northumberland or Durham, and are between sixteen and eighteen years of age. So far as it goes, the Newcastle College seems to furnish a thorough training in scientific knowledge and method.

WE have received from Mr. F. Abbott a paper read before the Royal Society of Tasmania, giving the result of his recent observations at the Private Observatory, Hobart Town, Tasmania, of η Argus. He thus summarises the results of his most recent observations. In the eye draft of the object η Argus, Feb. 1873, the principal stars appear to have retained their relative position as shown in the drawing of last year. The dark spaces are extending and becoming more undefined, gradually filling up with small stars, fully half as many again as shown in last year's drawing; the whole field of the telescope when directed to η is studded with stars from the 7th to the 12th magnitude, too numerous to count. I have on the present occasion omitted to make a drawing of the object, as in all probability before long photography will be applied both to this and other portions of the dense Nebula between it and κ Crucis—a thing much required.

A MAGNIFICENT work, in the shape of a Photographic Album of Ethnology ("Anthropologisch-Ethnologisches Album"), from the collections of the Berlin Anthropological Society, is about to be published in parts, by Wiegandt and Hempel, of Berlin, the photographs by C. Dammann, of Hamburg. Each part will contain five leaves 48 centimetres in length by 64 centimetres in breadth, each part in a separate portfolio. The contents will be arranged in tables containing from ten to twenty photographs each, and the price of each part is twelve thalers. The first part contains two tables illustrative of the East Coast of Africa, and three tables for Asia, illustrating Eastern Siberia, Japan, Siam, &c. Appended to each portrait is a brief description indicating the country, particular district, sex, and age of the original. The immense value of such a work to ethnologists is evident.

FROM the "Report of the Radcliffe Observer to the Board of Trustees," we see that a considerable amount of regular observatory work has been done during the past year, and that the establishment is in good condition.

IN a letter to the *British Medical Journal*, Mr. J. C. Galton refers to a specimen of a human heart in which the "moderator band" recently found by Prof. Rolleston in the Cassowary, and long known to be well developed in Ruminants as a strong fibrous cord, running in the right ventricle between its outer wall and the septum, is well developed as a thick muscular band. But he remarks that from it "some of the chordæ tendineæ of the tricuspid valve take origin." Prof. Rolleston also considers that one at least of the columnæ carneæ in man, which are unattached in the middle of their course, and are in connection with the musculi papillares of the tricuspid valve, is homologous with it. In the Ruminant, however, the band is quite free and of fibrous structure, and is apparently a much more specialised development than the uncertain muscular cords found in the human heart.

THE report of work contained in the "Proceedings of the Liverpool Naturalist's Field Club for the year 1872-3," appears to us, on the whole, gratifying. The Society made nine field excursions during last summer, and, considering the unsettled state of the weather, these were well attended. The working members of the Society, during these excursions, devote themselves mainly to botanical collecting, though the majority of those who make up the parties spend their time in visiting places of antiquarian and historical interest. Prizes are given for botanical collections, and we are afraid the Society do not take the precaution of urging upon collectors the danger of extirpating the rare plants of the districts visited in their eagerness to make up prize-taking collections. Several evening meetings were held during last winter, at the first of which Mr. Fisher gave a *résumé* of the Botanical gains of the Society during the excursions. The following valuable papers were also read at these meetings:—"On the Respiration and Germination of Plants," by Dr. Carter; "Corals and Coral Islands," by the Rev. H. H. Higgins, President; "On the Intimate Relations between the Animal and Vegetable Kingdoms," by Mr. Chantrell; "On the Sap of Plants, the Physical Causes of its Ascent, and its Composition," by Mr. Davies. We have also received an "Appendix to the Flora of Liverpool," containing a considerable number of additions to that valuable work, which we noticed on its appearance about a year ago.

IT is said that the scheme which has been on foot for some time past, having for its object the closer connection of St. Andrew's University with the neighbouring town of Dundee, by the establishment of an affiliated college there, on the same principle as the Science College at Newcastle is connected with the University of Durham, has fallen through, several of the St. Andrew's professors being of opinion that if this arrangement were entered into it would ultimately end in the University being transferred across the Tay.

THE first four parts of an "Illustrated International Review of the Universal Exhibition of Vienna, 1873," have come to hand. It is a handsome and well-illustrated folio, printed in French, German, and English, and promises to be an "absolutely complete encyclopædia of the Vienna Exhibition of 1873, at once descriptive, artistic, scientific, anecdotic, and biographical." If the prospectus is faithfully carried out, the work will be very valuable both in a scientific and an industrial point of view.

ADVICES to the 12th of June, dated Denver, U.S., make mention of satisfactory progress in the explorations conducted by Professor Hayden and his parties. One of the divisions of the survey at that time was established near Central City, in charge of Mr. Jackson, and consisted of Mr. Coulter as botanist, Mr. Carpenter as naturalist, and Mr. Cole as assistant naturalist. They had already obtained a large collection of plants and zoological objects, having spent two weeks high up in the mountains. Mr. Jackson had made about fifty negatives of the higher peaks, principally in the vicinity of Long's Peak. They expected to proceed shortly to the "Garden of the Gods." Mr. Gardner has been occupied in establishing his base line of triangulation. He has already erected three signal monuments thirty feet high, and twelve miles apart, all of which can be seen from the main range of mountains. One party is at work on Long's

Peak, in charge of Mr. Marvin, accompanied by Mr. Gardner, and another under Mr. Gannett, accompanied by Dr. Peale, as geologist, and Mr. Batty as naturalist. According to the *Denver News*, the cattle, finding these constructions extremely convenient places for scratching, and thinking them apparently erected for their accommodation, have at once commenced appropriating them to that purpose, and evidently with great satisfaction, as it is said that they concentrate in their vicinity for miles around.

"ANNALEN des Physikalischen Centralobservatoriums" is the German title of the record for 1871 of the work done at the great Physical Observatory of St. Petersburg. It is a very thick quarto in Russian and German, and contains full and well-arranged meteorological statistics for fifty-five Russian towns for the year 1871.

THE following are the principal additions to the Brighton Aquarium during the past week:—10 Thornback Rays (*Raia clavata*), 1 Large Tope (*Galeus canis*), 1 Large Smooth Hound (*Mustelus vulgaris*) 3 Three-bearded Rockling (*Motella tricirrata*), 1,000 Sticklebacks (*Gasterosteus spinosus*), 1 fine group of *Actinoloba dianthus* (orange variety); a Smooth Hound (*Mustelus vulgaris*) gave birth to seven young ones, which died immediately, or were born dead.

THE additions to the Zoological Society's Gardens during the past week include two Maugé's Dasyures (*Dasyurus maugæi*) from Australia, presented by Mr. George Heath; a Tytlers Paradoxure (*Paradoxurus tytleri*) from the Andaman Islands, presented by Mr. J. S. Campbell; a Bactrian Camel (*Camelus bactrianus*) from Asia; a Gibbon (*Hylobates* sp. ?); a Crowned Eagle (*Spizaëtus coronatus*) from Senegal; three Blue crowned Hanging Parrakeets (*Loriculus galgulus*) from Malacca; an Egyptian Fox (*Canis niloticus*); an Egyptian Vulture (*Neophron percnopteros*), purchased; an Ocelot (*Felis pardalis*) from America; a Hobby (*Hypotriorchis subbuteo*) from this country, and four red-billed Tree Ducks (*Dendrocygna autumnalis*) from America, deposited.

ON THE TEMPERATURE AT WHICH BACTERIA, VIBRIONES, AND THEIR SUPPOSED GERMS ARE KILLED*

WHILST a heat of 140° F. (60° C.) appears to be destructive to *Bacteria*, *Vibriones*, and their supposed germs in a neutral saline solution, a heat of 149° or of 158° F. is often necessary to prevent the occurrence of putrefaction in the inoculated fluids when specimens of organic infusions are employed. What is the reason of this difference? Is it owing to the fact that living organisms are enabled to withstand the destructive influence of heat better in such fluids than when immersed in neutral saline solutions? At first sight it might seem that this was the conclusion to be drawn. We must not, however, rest satisfied with mere superficial considerations.

The problem is an interesting one; yet it should be clearly understood that its solution, whatever it may be, cannot in the least affect the validity of the conclusion arrived at in my last paper, viz., that living matter is certainly capable of arising *de novo*. We were enabled to arrive at the conclusion above mentioned regarding Archebiosis by starting with the undoubted fact that a heat of 158° F. reduces to a state of potential death all the *Bacteria*, *Vibriones*, and their supposed germs which an organic infusion may contain. The inquiry upon which I now propose to enter, therefore, touching the degree of heat *below this point* which may suffice to kill such organisms and their supposed germs in an organic infusion, and touching the cause of the delayed putrefaction apt to take place in inoculated organic infusions which have been heated to temperatures above 140° and below 158° F., is one lying altogether outside the chain of fact and inference by which the occurrence of Archebiosis is proved.

* Extracts from a paper by Dr. H. Charlton Bastian, F.R.S., read before the Royal Society May 1, 1873.

It seems to me that the solution of the problems which form the subject of the present communication can only be safely attempted by keeping constantly before our minds two main considerations:—

Thus, in the experiments whose results it is now our object to endeavour to explain, the fluids have been inoculated with a compound consisting partly (*a*) of living units, and partly (*b*) of a drop of a solution of organic matter in a state of molecular change; so that in many cases where putrefaction has been initiated after the inoculating compound has been heated to certain temperatures, there is the possibility that this process of putrefaction may have been induced (in spite of the death of the organisms and their germs) owing to the influence of *b*, the dissolved organic matter of the inoculating compound; that is to say, the heat to which the mixture has been exposed may have been adequate to kill all the living units entering into the inoculating compound, although it may not have been sufficient to prevent its not-living organic matter acting as a ferment upon the infusion.

And there are, I think, the very best reasons for concluding that in all the cases in which turbidity has occurred after the organic mixtures have been subjected to a heat of 140° F. (60° C.) and upwards, this turbidity has been due, not to the survival of the living units, but rather to the fact that the mere dead organic matter of the inoculating compound has acted upon the more unstable organic infusions in a way which it was not able to do upon the boiled saline fluids.

The reasons upon which these conclusions are based are the following:—

1. Because the turbidity which has occurred in inoculated organic infusions that have been subjected to a temperature of 140° F. has always manifested itself appreciably later, and advanced much more slowly than in similar mixtures which had not been heated above 131° F.; whilst it has commenced even later, and progressed still more slowly, when occurring in mixtures previously heated to 149° F. Such facts might be accounted for by the supposition that exposure in these organic fluids to the slightly higher temperature suffices to retard the rate of growth and multiplication of the living units of the inoculating compound, although the facts are equally explicable upon the supposition that the later and less energetic putrefactions are due to the sole influence of the mere organic matter of the inoculating compound.

2. So far as the evidence embodied in the Tables goes, it tends to show that the more unstable different specimens of similar infusions are (that is, the stronger they are), the more rapidly and frequently does late turbidity ensue, and the more this late turbidity approaches, both in time of onset and in rate of increase, to that which occurs when inoculated infusions are not heated to more than 131° F.—when both living and non-living elements of the inoculating compound act conjointly as ferments. Such facts show quite clearly that where the intrinsic or predisposing causes of change are strong, there less potent exciting agencies are more readily capable of coming into play; but they still do not enable us to decide whether the exciting cause of this delayed turbidity is in part the living element whose vitality and rate of reproduction has been lowered by the heat, or whether the effects are wholly attributable to the mere organic matter of the inoculating compound.

So far, therefore, we have concomitant variations which are equally compatible with either hypothesis. But it will be found that each of the three succeeding arguments speaks more and more plainly against the possible influence of the living element, and in favour of the action of the organic matter of the inoculating compound, as an efficient exciting cause of the delayed putrefactions occurring in the cases in question.

3. As stated in my last communication,* when single drops of slightly turbid infusions of hay or turnip previously heated to 140° F. are mounted and securely cemented as microscopical specimens, no increase of turbidity takes place, although drops of similar infusions heated only to 122° F. do notably increase in turbidity (owing to the multiplication of *Bacteria*) when mounted in a similar manner. Under such restrictive conditions as these, in fact, a drop of an inoculated and previously heated organic infusion behaves in precisely the same manner as a drop of a similarly treated ammonic-tartrate solution. In each case, when heated to 140° F., turbidity does not occur, apparently because there are no living units to multiply, and because in

* See NATURE, vol vii. p. 435.

these mere thin films of fluid dead ferments are as incapable of operating upon the organic fluids as they are upon the ammonic-tartrate solutions.

4. Because, in the case of the inoculation of fluids which are not easily amenable to the influence of dead ferments, such as a solution containing ammonic tartrate and sodic phosphate, this delayed turbidity does not occur at all. Such inoculated fluids become rapidly turbid when heated to 131° F., though they remain clear after a brief exposure to a temperature of 140° F. When the living units in the inoculating compound are boiled, there is nothing left to induce turbidity in such solutions. The mere fact that these fluids do not undergo change when exposed to the air proves conclusively that they are very slightly amenable to the influence of the ordinary dead organic particles and fragments with which the atmosphere abounds. The absence of delayed turbidity in these fluids serves, therefore, to throw much light upon the cause of its occurrence in the organic infusions.

5. And, lastly, I can adduce crucial evidence supplied by the "Method of Difference," speaking with its accustomed clearness. Two portions of the same hay- or turnip-infusion can be inoculated in such a manner as to supply us with the information we require. In the one case we may employ a drop of a turbid ammonic-tartrate solution previously heated to 140° F., in which, therefore, the living units would certainly be killed: whilst in the other we may add an unheated drop of the same turbid saline solution to the organic fluid, and then heat this mixture also to the temperature of 140° F. The comparative behaviour of these two inoculated fluids (placed, in the ordinary manner, in previously boiled corked phials) should be capable of showing us whether the living elements of the inoculating compound were able to survive when heated in the organic infusion. If they did survive, the fluids inoculated in this manner ought to undergo putrefaction earlier and more rapidly than those inoculated with the drop of turbid fluid, in which we know that the *Bacteria*, *Vibriones*, and their supposed germs would have been reduced to a state of potential death. With the view of settling this question, therefore, the following experiments were made:—

Description of Experiments.	Results.	Inferences.
A. Boiled ammonic-tartrate solution, inoculated with an unheated drop of a similar solution turbid with *Bacteria*, &c.	Turbid in 40 hrs.	That boiled ammonic-tartrate solution is a fluid inoculable by living *Bacteria*, &c., and favourable for their growth and raoid multiplication.
B. Boiled ammonic-tartrate solution, inoculated with a drop of a turbid saline solution previously heated to 140° F.	Clear at expiration of 8th day.	That *Bacteria*, *Vibriones*, and their supposed germs are either killed or deprived of all power of multiplication when heated to 140° F. in this fluid.
C. Boiled turnip- and hay-infusions, inoculated with a drop of a turbid saline solution previously heated to 140° F.	Turnip-infusions turbid in 2½ days. Hay-infusions clear at expiration of 8th day.	The precisely similar behaviour of the turnip- and hay-infusions of series C and series D respectively shows that *Bacteria*, *Vibriones*, and their supposed germs are as inoperative in series D as they are known to be in series C; whilst the behaviour of the hay-infusions shows that they are little amenable to the influence of the drop of the saline fluid when its living units are killed.
D. Boiled turnip- and hay-infusions, inoculated with a drop of an unheated turbid saline solution, the inoculated fluid being subsequently heated to 140° F.	Turoip-infusions turbid in 2½ days. Hay-infusions clear at expiration of 8th day.	
E. Boiled turnip- and hay-infusions, inoculated with a drop of an unheated saline solution, the inoculated fluid being subsequently heated to 131° F.	Turnip-infusions turbid in 28 hrs. Hay-infusions turbid in 38 hrs.	Shows that a heat of 131° F. is not sufficient to kill *Bacteria*, *Vibriones*, and their supposed germs in organic infusions, and, again, that turnip-infusions are more rapidly iofluenced by such an inoculating agent than some hay-infusions.*

No experiments could speak more decisively. Those of series B show that *Bacteria*, *Vibriones*, and their supposed germs are either actually or potentially killed when heated to 140° F. in the neutral saline fluid, which the experiments of series A show

* These experiments of series C, D, and E were many times repeated with specimens of the same turnip- and hay-infusions, the specific gravity of the former being about 1008 and that of the latter 1005. Different specimens of hay especially vary so much that it becomes absolutely essential to use portions of the same infusion for the comparative experiments of these different series.

to be eminently favourable for their growth and reproduction. Being certain, therefore, that the living units are killed in the drops with which the fluids of series C were inoculated (because they were drops of the same fluid as was employed in series B), we may be equally certain that the turbidity and putrefaction which did ensue in the turnip-solutions of series C were due to the influence of the mere dead constituents of these drops of the turbid saline fluid; whilst, seeing that the behaviour of the fluids of series D was precisely similar to those of series C, we have a perfect right to infer that this series of fluids (D) was as devoid of living units as those of C are known to be—that is, that *Bacteria*, *Vibriones*, and their supposed germs are killed by the temperature of 140° F. in organic fluids, just as they are in saline fluids, although, as shown by the experiments of series E, they do not succumb to a heat of 131° F.

The evidence now in our possession shows, therefore, that whilst the temperature at which living ferments cease to be operative varies within very narrow limits (131°–140° F.), that which destroys the virtues of non-living ferments varies within much wider limits, and depends not only upon the amount of heat employed, but also upon the nature of the putrescible or fermentable liquid to which such ferment is added, in conjunction with the degree of heat and other conditions to which the mixture is subsequently exposed.* Here, therefore, we have evidence as to the existence of a most important difference between living and not-living ferments, which has always been either unrecognised or more or less deliberately ignored by M. Pasteur and his followers.† This difference is, moreover, thoroughly in accordance with the broad physico-chemical theory of fermentation which has been so ably expounded by Baron Liebig and others, and the truth of which may now be regarded as definitely established. According to this theory "living" matter, as a ferment, would take rank merely as a chemical compound having a tolerably definite constitution; and this, we might reasonably infer, would, like other chemical compounds, be endowed with definite properties, and amongst others that of being decomposed or radically altered by exposure to a certain amount of heat. Looked at also from this essentially chemical point of view, it would be only reasonable to expect that the molecular movements of living ferments with a lowered vitality might not be more marked or energetic than those which many not-living organic substances are apt to undergo; and this being the case, we might expect that there would often be a great practical difficulty in ascertaining whether a ferment belonging to the arbitrary and artificial (though, in a sense, justifiable and natural) category of "living" things had or had not been in operation.

Dr. Bastian then refers to certain statements made by M. Pasteur, and afterwards classifies the various fermentable fluids under three main divisions:—I. Self-fermentable fluids; II. Fluids which will not ferment without the aid of unheated organic matter, either not-living or living; III. Fluids which will only ferment under the initiating influence of living matter.

Dr. Bastian's conclusions from these investigations are thus expressed:—

Thus it can now be proved, by evidence of a most unmistakable nature, that the process of putrefaction which invariably occurs in previously boiled putrescible infusions contained in flasks with narrow but open necks is not commonly (is, perhaps, only very rarely) initiated by living germs or organisms derived from the atmosphere; it can also be proved that putrefaction and the appearance of swarms of living organisms may occur in some boiled fluids when they are simply exposed to air which has been filtered through a firm plug of cotton-wool or though the narrow and bent neck of a flask, to air whose particles have been destroyed by heat, or even in fluids hermetically sealed in

* See "The Beginnings of Life," vol. i. p. 437.

† See, for instance, all M. Pasteur's celebrated experiments in which he had recourse to an "ensemencement des poussières qui existent en suspension dans l'air," as recorded in chaps. iv. and v. of his memoir in "Ann. de Chimie et de Physique," 1862. M. Pasteur was engaged in an investigation, one of the avowed objects of which was to determine whether fermentation could or could not take place without the intervention of living organisms, which M. Pasteur held (in opposition to many other chemists) to be the only true ferments. In his inoculating compound (dust filtered from the atmosphere), there was, as M. Pasteur was fully aware, a large amount of what his scientific opponents considered non-living ferment, whilst *possibly* there existed a certain number of living ferments. In explaining the results of his experiments, however, M. Pasteur and others thought he was pursuing a logical and scientific method when he attributed these results to the action of the possibly existing element of the inoculating compound, whilst he ignored altogether the other element which was certainly present in comparatively large quantity, and the testing of whose efficacy was the ostensible object of his research.

flasks from which all air has been expelled. The evidence in our possession is therefore most complete on this part of the subject: it shows beyond all doubt, not only that putrefaction may and does very frequently occur under conditions in which the advent of atmospheric particles, whether living or dead, is no longer possible, but also that living particles derived from the atmosphere can only be very rare and altogether exceptional initiators of the putrefaction which invariably occurs in previously boiled infusions exposed to the air.

Again, the evidence which we now possess with reference to the influence of heat upon *Bacteria*, *Vibriones*, and their supposed germs is no less decisive. It has been unmistakably proved that such organisms and their imaginary germs are either actually or potentially killed by a brief exposure to the temperature of 140° F. when in the moist state; and it had also been previously established that they are invariably killed by desiccation even at much lower temperatures.*

But if living germs do not come from the air to contaminate the previously boiled fluids, and if it is not possible for any of them to have escaped the destructive influence of heat in the boiling fluid or on the walls of the vessel in which the fluid is contained, what can be the mode of origin of the swarms of living things which so rapidly and invariably appear in such infusions when contained in open flasks, and which so frequently appear when the infusions are contained in flasks whose necks are closed against atmospheric particles of all kinds? They can only have arisen by the process which I have termed Archebiosis.

Conclusions

If a previously boiled ammonic-tartrate solution remains free from *Bacteria* and *Vibriones* when exposed to the air, it is because the air does not contain living organisms of this kind or their supposed germs, and because mere dead organic particles are not capable of initiating putrefaction in such a fluid.

And if ordinary organic infusions previously boiled and exposed to the air do rapidly putrefy, though *some* of the same infusions when exposed only to filtered air remain pure, it is because such fluids are, in the absence of living units, quite amenable to the influence of the dead organic particles which the air so abundantly contains, although they are not self-fermentable.

Whilst if other more changeable fluids, after previous boiling, when exposed to filtered air or cut off altogether from contact with air, do nevertheless undergo putrefaction or fermentation, it is because these fluids are self-fermentable, and need neither living units nor dead organic particles to initiate those putrefactive or fermentative changes which lead to the evolution of living organisms.

* See the experiments and conclusions of Dr. Burdon Sanderson in Thirteenth Report of Med. Officer of Privy Council. p. 61. This fact of the inability of these organisms and their germs to resist desiccation shows the futility of some objections which have been from time to time raised by those who thought that *Bacteria*, *Vibriones*, and their germs might resist the destructive influence of heat by adhesion to the glass above the level of the fluid, or even in the fluid itself, just as dried and very thick-coated seeds have been known to do. Dry heat would seem to be even more fatal to such organisms and their germs than a moist heat of the same degree, owing to their extreme inability to resist desiccation; if they become dry they are killed at a temperature of 104° F., whilst if they remain moist they succumb, as we have seen, to a temperature of 140° F.

SCIENTIFIC SERIALS

THE June number of the *Journal of Anatomy and Physiology* contains several papers of special interest, as well as the excellent summaries by Profs. Turner and Rutherford, of the progress of Anatomy and Physiology during the last six months. Prof. Turner describes, for the first time, the Visceral Anatomy of the Greenland Shark (*Læmargus borealis*) from two specimens caught near the Bell Rock. The larger was 11 feet 8 inches long, and the other 8½ feet: they were both females. The most important peculiarities of this fish, wherein it differs from other sharks are, that the *bursa entiana* is not developed; that there are two large duodenal cæca, one of which is closely adherent to the pyloric tube, as well as a true pancreas, corresponding with the similar condition found by Alessandrini in the Sturgeon; and that there are no oviducts, so that the ova must be discharged into the peritoneal cavity. From these peculiarities the author places *Læmargus* in a family by itself, named by him *Læmargidæ*.—Prof. Turner also, in a short paper on the so-called claw at the end of the tail of the lion, shows that no true claw exists, but that the tip of the tail is hairless, and becomes hard on drying.—Prof. Rutherford tabulates experiments proving that the retardation of the pulse in the rabbit, which follows closure of the nostrils, depends on the obstruction of the respiration, and not as Drs. Brown-Séquard and Sanderson supposed, on direct reflex action. Mr. Dewar and Dr. McKendrick describe experiments on the Physiological Action of Light, an account of which has already appeared in this journal.—Mr. Blake, of San Francisco, has a paper on the action of the salts of the metals sodium, lithium, cæsium, &c., when introduced directly into the blood. Mr. A. H. Smee, in a paper on the physical nature of the coagulation of the blood, endeavours to prove that it coagulates in obedience to a purely physical law, namely, the power of soluble colloid matter to pectinise, or spontaneously to coagulate. Mr. Garrod, on the law which regulates the frequency of the pulse, proposes as a substitue for that given by Marey, the following:—the heart re-commences to beat when the arterial tension has fallen an invariable proportion, this being the only possible explanation of the facts that pulse rate varies with arterial resistance and not with blood pressure. He also gives a new theory of the source of nerve force.—Dr. Charles, Prof. Curzon, and Prof. Drachmann, record peculiarities in anthropotomy, the first in the arterial system, the second in the muscular and nervous system, and the third in the muscular.—There is an excellent and very careful review, by Mr. Trotter, of the Rev. Samuel Haughton's "Principles of Animal Mechanics," which will be very valuable to many physiologists, who here have the opportunity of seeing the opinion of a mathematician, who is also a biologist, of a work which might by itself lead them to think that the physiogical basis for work was in a better position than it really is.

Bulletin Mensuel de la Société d'Acclimatation de Paris for June. A great portion is devoted to the description of the best modes of rearing silkworms and the more suitable kinds of food for feeding them. A paper is devoted to the Japanese Mulberry (*Morus japonica*), which is being introduced into France as producing a superior food for the silkworm. —The cultivation of various kinds of beans and melons is advocated by M. Bossin, and his paper might be read with advantage in this country, where these vegetables are not sufficiently valued as an article of diet. Not only the acclimatisation of useful, but the destruction of hurtful animals, plants, and insects, forms part of the programme of the society, and we have therefore some remarks on insecticides and on the preservation of insectivorous birds.—The American notes on pisciculture, on the grey wolf, and the commerce of Chicago are interesting. A black monkey from Sumatra has just arrived at the Jardin d'Acclimatation, but it is not expected to live.

SOCIETIES AND ACADEMIES

London

Quekett Microscopical Club, July 25.—Dr. Braithwaite, F.L.S., president, in the chair.—This being the annual meeting, the report of the committee for the past year was read, and testified to the continued prosperity of the club, which now numbers 570 members.—The president delivered the annual address, in the course of which he noticed the progress of microscopical investigation in Botany and Zoology during the past year.—The ballot then took place for the election of officers. Dr. Braithwaite was re-elected president; Dr. Matthews, Messrs. B. T. Lowne, T. W. Burr, and C. F. White, vice-presidents; and Messrs. Bywater, Crisp, Hailes, Hind, Waller, and T. C. White, were elected to fill the six vacancies on the committee. Mr. J. E. Ingpen succeeded Mr. T. C. White, who retires from the office of hon. sec. (owing to increase of his professional duties), after four years of unremitting and valuable service. The proceedings terminated with the usual *conversazione*.

Belgium

Royal Academy of Sciences, May 13.—Reports were given in on the following papers:—On the Superficial Tension of Liquids considered in reference to certain movements observed on their surface, by M. G. Van der Mensbrugghe, which it was resolved to print in the *Mémoires*.—On the Osculatory Sphere, a note by M. L. Saltel, which is printed in the *Bulletin*. —On the chloric acetonitriles, by M. L. Bisschopinck, also printed in the *Bulletin*.—Essay on the state of vegetation at the

epoch of the Heersien Marls of Gelinden, by Count G. de Saporta and Dr. A. F. Marion. It was resolved to print this paper with the plates in the *Mémoires*.—The following communications were made:—On frozen alcoholic drinks carried to very low temperatures, and on the cooling and freezing of ordinary or sparkling wines, which will appear in the *Bulletin* for June.—Third addition to the synopsis of the Caloptergines, by M. de Selys Longchamps. His first list was published in 1853, and additions in 1859 and 1869; the present long list contains descriptions of many new species, as well as corrections of and additions to species already described. The author is indebted for the greater part of his material to Mr. MacLachlan.

PHILADELPHIA

Academy of Natural Sciences, May 6.—Dr. Carson, vice-president, in the chair. Double Flowers in *Epigæa repens*.—Mr. Thomas Meehan observed, that on several occasions, during the few past years, it had been noticed among the *variations in nature*, that the tendency to produce double flowers was, by no means, the special prerogative of the florist to originate. Many of our commonest wild flowers, which no one would think of cultivating, had double forms in cultivation which were no doubt originally found wild. Thus we had a double *Ranunculus acris*, *R. bulbosus*, *R. Ficaria*, *R. repens*, and some others. There were, in plants, two methods by which a double flower was produced. The axis of a flower was simply a branch very much retarded in its development, and generally there were, on this arrested branch, many nodes between the series forming the calyx or corolla, and the regular stamens and carpels, which were entirely suppressed. But when a double flower was produced, sometimes these usually suppressed nodes would become developed, in which case there was a great increase in the number of petals, without any disturbance in the staminal characters. But at other times there was no disturbance in the normal character of the axis. The stamens themselves merely became petaloid. This was the case in the *Epigæa*, recently found by Dr. Darrach.—Influence of Cohesion on Change of Characters in *Orchideæ*.—Mr. Meehan also said that in the early part of the winter he had exhibited some flowers of *Phaius Tankervillæ*, in which, by the mere cohesion of one of the dorsal petals with the column, a flower differing very much from the general condition was the result. Since that time Dr. Maxwell T. Masters, in the issue of the *Gardener's Chronicle* for April 12th, notices the receipt of a *Phaius Wallichii* in which there had been produced three spurs and regular petals, looking, Dr. M. says, rather like those of a gladiolus than of an orchid.

May 13.—Dr. Ruschenberger, president, in the chair. The following paper was presented for publication:—"Observations on Nests of *Sayornis fuscus*," by Thos. G. Gentry.—Prof. Cope exhibited and described some extinct turtles from the Eocene strata of Wyoming.

May 20.—"Descriptions of new species of Orthoptera, collected in Nevada, Utah, and Arizona, by the Expedition under Lieut. G. M. Wheeler," by Cyrus Thomas.—"Observations on the Habits of the Neuters of *Formica sanguinea*," by T. G. Gentry.—*Lilium Washingtonianum*.—Mr. Thomas Meehan referred to a paper by Prof. Alphonso Wood, entitled a "Sketch of the Natural Order of Liliaceæ," of the Pacific coast, published in the volume of the Proceedings for 1868, in which he describes a "new species" of Lilium, as *L. Washingtonianum*, giving, as a reason for the name, that it was generally known as the "Lady Washington" by the miners. Prof. W. said, in his paper, that it was remarkable so fine a plant had been overlooked by other botanists. It so happens that it had not been overlooked, but had been described ten years previously by Dr. Kellogg, in the Proceedings of the California Academy for 1858.—"On a Species of Delphinus," by Dr. H. C. Chapman.

PARIS

Academy of Sciences, July 21.—M. de Quatrefages, president, in the chair.—The following papers were read:—Note on changes of rate in isochronous regulators, by M. Yvon Villarceau.—Third note on guano, by M. Chevreul.—New researches tending to prove that the co-ordinating power over bodily movements lies in the cerebellum, &c., by M. Bouillaud.—The laws of friction and concussion on the thermo-dynamical theory, by M. A. Ledieu.—On the movement of a spherical segment on an inclined plane, by Gen. Didion.—On the spectra of iron, and some other metals, by Father A. Secchi. The author had failed when examining the iron spectrum given by a battery of fifty cells, to observe the line 1474K, and he gave, in the present paper, an account of a further search for it. The same battery power, with new acids, was used; various samples of iron were burnt in the arc, either as iron poles or placed in hollow carbon points, and the sunlight was reflected into the spectroscope with a heliostat. The line in question could not be found in any sample of iron used. His other observations are on the "structure" spectra of carbon and aluminium; he observes that each line of the columnar bands is itself resolvable into a mass of fine lines.—On the permeability of the Fontainbleau sands, by M. Belgrand.—On the movement of the wash produced in artificial canals, and on causing water to rise along an inclined bank to a sensibly constant height. A letter from Mr. Nordenskiöld, dated Mossel Bay, latitude 79° 54′ N. was read by M. Daubrée.—New spectroscopic observations of the sun which do not agree with certain sun-spot theories, by Father Tacchini. The theories are those of M. Faye and Father Secchi. The author describes watching a facula over the sun and observing its appearance on the limb which was accompanied by the reversal of large numbers of metallic lines in the chromosphere. This, Tacchini considered as evidence of an eruption, and as militating against Faye's theory because he considers that theory not to allow of eruptions, and against Secchi also, he having stated that faculæ were eruptions, and spots the erupted matter, and yet this facula had no spots during half a revolution.—On Euler's constant and Binet's function, by M. E. Catalan.—Researches on electric condensation, by M. V. Neyreneuf.—Studies on nitrification in soils, by M. T. Schlœsing.—On a combination of picric acid, with acetic anhydride, by MM. Tommasi and David. The authors considered this body as a picrale, in which one atom of metal is replaced by acetyl.—On pyrogallic acid in the presence of iodic acid, by M. Jacquemin.—On a natural combination of ferric and cuprous oxides, and on the production of atacamite, by M. C. Friedel.—On the spontaneous changes of eggs, by M. Gayon.—An attempt to determine, by comparative embryology, the analogous portions of the intestines in the superior vertebrata, by M. Campana. During the meeting, an election was made to the place of *Membre libre*, vacant by the death of M. Verneuil. M. de Lesseps obtained 33 votes, M. Breguet 24 votes, MM. du Moncel, Jacquemin and Sedillot, 1 each. M. de Lesseps was therefore declared duly elected.

THURSDAY, AUGUST 7, 1873

GUSTAV ROSE

THE son-in-law of Gustav Rose, Professor G. vom Rath, has sent us the Nekrolog which affection and custom in the Fatherland unite in issuing in honour of those who are no more.

The first line of this tribute to the memory of the great mineralogist tells truly that Germany has lost one of her great ones in this learned and noble man: but it is for us to say that it is even a wider world than his fatherland that has lost in him one of its conspicuous citizens. For the two brothers Heinrich and Gustav Rose formed a double star in the constellation of illustrious men who have illuminated with a brilliancy all its own the first half of this great century; and, indeed, for now fifty years their twin lights have guided the course of their contemporary and of a younger generation of wayfarers on the track of Science.

Certainly the death of a man like Gustav Rose is calculated to call up some wonderment in our minds as we look back over the brief period that even his 76 years of life embrace, and think in what relation that little space of time stands to the long history of man in regard to the sciences that these two illustrious brothers cultivated so pertinaciously and so well. Berzelius spoke of looking back within his own memory to the dark age of phlogistic chemistry. Heinrich Rose first reduced to a scientific system the methods of inorganic chemical analysis, as J. von Liebig did afterwards for organic chemistry; it is but yesterday that the one, and but a few brief years since the other died. And now Gustav Rose, the first man in Germany who used the reflective goniometer, has followed them and Mitscherlich and Haussmann, and Haidinger. There still remain Breithaupt and Naumann, Wöhler, and a few other honoured men on whom the patriarch's mantle must successively devolve. Let us at least pay the tribute due to the memory of the last of these illustrious workers whose chair is empty by endeavouring to take a survey of the work he did, and by recognising the debt we owe him for the results that have accrued to our knowledge from the toil "Ohne Hast und ohne Rast," of fifty out of his seventy-six years, and no less for the example he has set of method and of energy in achieving them.

The sciences that Gustav Rose devoted himself to, crystallography and mineralogy, have been for many years so little or so superficially studied in England, that probably few of our countrymen are familiar with the continuous succession and admirable quality of the work turned out from the study of one of the soundest-minded, and, let us add, one of the soundest-hearted men that Germany ranked among her sons.

His country's troubles, though they ended as far as the great war was concerned in 1815, had called into the ranks even the youngest of the four brothers Rose. Their father, a not undistinguished pharmaceutical chemist in Berlin, had died in 1807, leaving his children to the care of his widow, who appears to have borne out the tradition of able men owing much to remarkable characteristics in their mothers. Young Gustav was not old enough in the days of the terrible conflicts to have borne his musket. But he was seventeen, in time to make the long march from Berlin to Orleans; and after the peace in 1815 he set himself to obtain a livelihood in the occupation of mining. Overtaken by an attack of inflammation of the lungs, his thoughts became directed into a new direction. For the contagious passion for the pursuit of truth in its most tangible form by the path of natural science seized him by contact with his elder brother Heinrich; and Gustav followed his example in going to Stockholm for a similar object to that which has drawn so many Englishmen and English-speaking men since to Germany. Berzelius was then in Sweden what afterwards were Heinrich Rose, Wöhler, Liebig, in the Fatherland; the great master in the science as in the practice of chemistry. Gustav Rose was twenty-six when he ceased to be a student, and of the fifty years that have run out their sands since 1823, there is scarce one that has not recorded some work or memoir by the great crystallographer; and in some of those years he produced several.

And Gustav Rose was a crystallographer and mineralogist in the completest sense. The first man in Germany, as we have said, who adopted the use of Dr. Wollaston's reflective goniometer, he aided Mitscherlich in his discovery of Isomorphism; and this must have been one of his earliest labours.

His first paper was an exercise in Latin on the Crystallography of Sphene; and in 1830 he brought out his treatise on Crystallography, in which recognising the simplicity introduced by the use of geometrical axes as employed by Weiss, he adopted that method of expression for the relations of the faces of a crystal, a method which has in fact been only carried out to its last logical form and simplest expression by the admirable system of our countryman Prof. W. H. Miller.

It is not easy now to transport ourselves back to the time when scientific men of high eminence deliberately closed, or rather refused to open, their eyes to the chemical composition of a mineral as the most fundamental point in its definition and description, and to its chemical relations as affording the only philosophical basis on which to form a classification of minerals. But this difficulty of placing ourselves in the position taken up by Mohs and his school, very much arises from our not appreciating the situation of chemical and crystallographic research in their mutual valuation twenty years before the death of Mohs. We may for instance take two garnets, one consisting of aluminium and magnesium silicate, another of iron and calcium silicate. The two minerals contain notably differing proportions of the only ingredient they have in common, namely silica; and yet their crystalline forms are the same, and the mineralogist could not fail to recognise so close a parallelism and similarity between the two minerals as to compel him to unite them under one general "natural-history" division.

The chemistry of that day, however, was not yet ripe for acknowledging such a classification. But when, on the other hand, the mineralogist assembled under one group minerals that differed in the way that, for instance, Linavite and blue copper carbonate (chessylite) differ in their chemical composition, or such widely different minerals as diamond and topaz, on the ground that they were hard and lustrous, and had the character of precious

stones; then the remonstrance of the chemist was founded in truth and reason.

It was the discovery of isomorphism that explained the anomalies and enigmas which thus in many cases seemed to justify the mineralogist in standing apart from the chemist, and preferring to discriminate, define, and classify minerals by appealing to superficial characteristics, rather than to the most fundamental feature of such bodies, their chemical molecular structure.

It came now to be seen that in the language of the earlier chemistry alumina and sesquioxide of iron, on the one hand, were able to represent the same ingredient in the garnet, while on the other hand, also, the lime, the magnesia, and the protoxide of iron might equally represent one another in the silicate in question, provided that the chemical structure of the compound was not altered, that is to say, could be expressed by a general formula that was equally applicable to each variety of the mineral; the identity of the crystallographic features of all those garnets being the evidence that the unity of the mineral type had not been overstepped by the interchanges of the elements. The application of this great discovery left chemistry master of the situation, and relegated into the regions of darkness the systems of classification that were not built on chemical and crystallographic principles. It was Mitscherlich, aided as vom Rath tells us by the young Gustav Rose, who made this grand announcement to the world in the year 1823. The light which was thus shed on the dark and till then uncertain problems that might connect the crystalline form with chemical structure, gave, as it were, new life to the vigorous school that owed its chemical precision to the great Professor at Stockholm, the school to which the two Roses and Wöhler belonged. The purely chemical problems of mineralogy received their constant attention; and Gustave Rose, by publishing his crystallography, asserted the co-ordinate functions of the goniometer and the balance in the future discussions of all the larger questions of the mineralogist.

He, in fact, unconsciously perhaps, was now initiating the method to which, with a fine unity of purpose, he adhered through his life.

Thus, for instance, we find him in 1831-33 discussing the somewhat paradoxical resemblance in the crystallographic constants of the minerals augite and hornblende, as suggested by Uralite, a mineral uniting the outline form of the one with the internal structure of the other; in fact a pseudomorph of hornblende after the form of augite.

Then in 1836 came his masterly memoir on the forms of Aragonite, the distinction of which from calcite had been established by Haüy in the beginning of the century. Afterwards, among a mass of works, we find memoirs on the differences of crystallographic habit in Albite, and the nearly related variety of the same felspar pericline, a subject to which he returned in later times; on the dimorphism of iridium, of palladium, and again of zinc; several treating on the marvellous connection by which certain kinds of hemisymmetry in crystals are associated with the localisation on them of opposite electric conditions under changes of temperature (pyroelectricity), which he illustrated in the case of the tourmaline, and among his latest memoirs by a most masterly one on pyrites and cobalt-glance. Quartz he made an object of especial study, explaining the character of its twin forms; and no memoirs in the whole range of crystallographic research, not excepting the splendid work in which Des-Cloiseaux capped, as it were, the labour of Rose, can surpass, in originality and precision, that by this great master on the crystallography of quartz.

Meteorites and the minerals which they contain have challenged the attention and been a sort of exercising-ground for several of the great mineralogists of Germany. Berzelius, indeed, set the example, but it was Rose who, in 1825, measured the first olivine crystal from the Pallas meteorite, and he, Haidinger, Breithaupt, and Wöhler, have all contributed invaluable material for the scientific history of these very difficult and interesting objects of investigation. And to G. Rose we owe the most penetrating insight into their structure, and the best attempt thus far made at classifying them. So, too, the sum of his thought and labour on the classification of minerals was given in his "crystallo-chemische mineral-system," published twenty-one years ago, in which he, so to say, demolished, by leaving no further excuse for perpetuating, the system which was identified with the name of Mohs, or indeed any other system to which chemical law was not the master key.

But one great work that Gustave Rose might have done, and better done perhaps than any living man, was the writing a treatise on Petrography. Mineralogy, the science of minerals, stands to petrography, the science that describes rocks and investigates their history, somewhat as biography stands to history itself, or as histology to physiology. The reason why a geologist is hardly ever a master of petrography is that he is so seldom, in England, at least, a mineralogist. And it is precisely because Gustav Rose was, and Naumann is, a complete mineralogist and crystallographer, and that both have profoundly studied the characters of the minerals in association which form rocks, that either of these two veteran professors might have written—alas! a month ago we might have said may yet write—such a treatise on rocks as probably no other living man could write. Gustav Rose began an admirable training in the field for such a study when, in the company of A. von Humboldt and G. Ehrenberg, he traversed European Russia and found himself among the rocks of the Ourals in 1829. The results of this historical progress were given to the world in two volumes in 1837-1842. The memoirs which he published subsequently to this time and to his becoming full professor (he had been extraordinary professor since 1826) of mineralogy at Berlin, treat very frequently of rock minerals; and indeed deal, in the majority of instances, with those more ordinary minerals which perform an important function as constituents of rocks; quartz, felspar, mica, hornblende, augite, seem never to weary him in observation or exhaust his powers of telling some new fact regarding them. One of his latest papers on the very common mineral, mica, is one of the most admirable of his researches. It was published, like most of his memoirs, in Poggendorft's *Annalen*, and treated on the interpenetration by one another, of various kinds of mica, and of these, with hematite and pennine.

It would be unnecessary, for the purpose of this slight sketch of Gustav Rose's labours, to go further into de-

tails regarding his works. He is gone; but his work lives after him.

The two Roses were men of a distinguished presence. Heinrich was the taller, but each was a man of spare and somewhat stately figure, with an eye of peculiar force and truthfulness of glance; an eye that spoke out the character of the man, that beamed with kindliness and was ever staunch to truth. N. S. M.

CHALLIS'S "MATHEMATICAL PRINCIPLES OF PHYSICS"

An Essay on the Mathematical Principles of Physics, &c. By the Rev. James Challis, M.A., F.R.S., F.R.A.S., Plumian Professor of Astronomy and Experimental Philosophy in the University of Cambridge, and Fellow of Trinity College. (Cambridge: Deighton, Bell, and Co., 1873.)

THIS essay is a sort of abstract or general account of the mathematical and physical researches on which the author has been so long engaged, portions of which have appeared from time to time in the *Philosophical Magazine*, and also in his larger work on the "Principles of Mathematics and Physics." It is always desirable that mathematical results should be expressed in intelligible language, as well as in the symbolic form in which they were at first obtained, and we have to thank Professor Challis for this essay, which though, or rather because, it hardly contains a single equation, sets forth his system more clearly than has been done in some of his previous mathematical papers.

The aim of this essay, and of the author's long-continued labours, is to advance the theoretical study of Physics. He regards the material universe as "a vast and wonderful *mechanism*, of which not the least wonderful quality is, its being so constructed that we can understand it." The Book of Nature, in fact, contains elementary chapters, and, to those who know where to look for them, the mastery of one chapter is a preparation for the study of the next. The discovery of the calculation necessary to determine the acceleration of a particle whose position is given in terms of the time led to the Newtonian epoch of Natural Philosophy. The study from the cultivation of which our author looks for the "inauguration of a new scientific epoch," is that of the motion of fluids, commonly called Hydrodynamics. The scientific method which he recommends is that described by Newton as the "foundation of all philosophy," namely, that the properties which we attribute to the least parts of matter must be consistent with those of which experiments on sensible bodies have made us cognizant.

The world, according to Professor Challis, is made up of atoms and æther. The atoms are spheres, unalterable in magnitude, and endowed with inertia, but with no other property whatever. The æther is a perfect fluid, endowed with inertia, and exerting a pressure proportional to its density. It is truly continuous (and therefore does not consist of atoms), and it fills up all the interstices of the atoms.

Here, then, we have set before us with perfect clearness the two constituents of the universe: the atoms, which we can picture in our minds as so many marbles; and the æther, which behaves exactly as air would do if Boyle's law were strictly accurate, if its temperature were invariable, if it were destitute of viscosity, and if gravity did not act on it.

We have no difficulty, therefore, in forming an adequate conception of the properties of the elements from which we have to construct a world. The hypothesis is at least an honest one. It attributes to the elements of things no properties except those which we can clearly define. It stands, therefore, on a different scientific level from those waxen hypotheses in which the atoms are endowed with a new system of attractive or repulsive forces whenever a new phenomenon has to be explained.

But the task still before us is a herculean one. It is no less than to explain all actions between bodies or parts of bodies, whether in apparent contact or at stellar distances, by the motions of this all-embracing æther, and the pressure thence resulting.

One kind of motion of the æther is evidently a wave-motion, like that of sound-waves in air. How will such waves affect an atom? Will they propel it forward like the driftwood which is flung upon the shore, or will they draw it back like the shingle which is carried out by the returning wave? Or will they make it oscillate about a fixed position without any advance or recession on the whole?

We have no intention of going through the calculations necessary to solve this problem. They are not contained in this essay, and Professor Challis admits that he has been unable to determine the absolute amount of the constant term which indicates the permanent effect of the waves on an atom. This is unfortunate, as it gives us no immediate prospect of making those numerical comparisons with observed facts which are necessary for the verification of the theory. Let us, however, suppose this purely mathematical difficulty surmounted, and let us admit with Professor Challis that if the wave-length of the undulations is very small compared with the diameter of the atom, the atom will be urged in the direction of wave-propagation, or in other words *repelled* from the origin of the waves. If on the other hand the wave-length is very great compared with the diameter of the atom, the atom will be urged in the direction opposite to that in which the waves travel, that is, it will be *attracted* towards the source of the waves.

The amount of this attraction or repulsion will depend on the mean of the square of the velocity of the periodic motion of the particles of the æther, and since the amplitude of a diverging wave is inversely as the distance from the centre of divergence, the force will be inversely as the square of this distance, according to Newton's law.

We must remember, however, that the problem is only imperfectly solved, as we do not know the absolute value of this force, and we have not yet arrived at an explanation of the fact that the attraction of gravitation is in exact proportion to the mass of the attracted body, whatever be its chemical nature. (See p. 36.)

Admitting these results, and supposing the great ocean of æther to be traversed by waves, these waves impinge on the atoms, and are reflected in the form of diverging waves. These, in their turn, beat other atoms, and cause attraction or repulsion, according as their wave-length is great or small. Thus the waves of shortest

period perform the office of repelling atom from atom, and rendering their collision for ever impossible. Other waves, somewhat longer, bind the atoms together in molecular groups. Others contribute to the elasticity of bodies of sensible size, while the long waves are the cause of universal gravitation, holding the planets in their courses, and preserving the most ancient heavens in all their freshness and strength. Then besides the waves of æther, our author contemplates its streams, spiral and otherwise, by which he accounts for electric, magnetic, and galvanic phenomena.

Without pretending to have verified all or any of the calculations on which this theory is based, or to have compared the electric, magnetic, and galvanic phenomena, as described in the Essay, with those actually observed, we may venture to make a few remarks upon the theory of action at a distance here put forth.

The explanation of any action between distant bodies by means of a clearly conceivable process going on in the intervening medium is an achievement of the highest scientific value. Of all such actions, that of gravitation is the most universal and the most mysterious. Whatever theory of the constitution of bodies holds out a prospect of the ultimate explanation of the process by which gravitation is effected, men of science will be found ready to devote the whole remainder of their lives to the development of that theory.

The only theory hitherto put forth as a dynamical theory of gravitation is that of Lesage, who adopts the Lucretian theory of atoms and void.

Gravitation on this theory is accounted for by the impact of atoms of incalculable minuteness, which are flying through the heavens with inconceivable velocity and in every possible direction. These "ultramundane corpuscules" falling on a solitary heavenly body would strike it on every side with equal impetus, and would have no effect upon it in the way of resultant force. If, however, another heavenly body were in existence, each would screen the other from a portion of the corpuscular bombardment, and the two bodies would be attracted to each other. The merits and the defects of this theory have been recently pointed out by Sir W. Thomson. If the corpuscules are perfectly elastic one body cannot protect the other from the storm, for it will reflect exactly as many corpuscules as it intercepts. If they are inelastic, as Lesage supposes, what becomes of them after collision? Why are not bodies always growing by the perpetual accumulation of them? How do they get swept away? and what becomes of their energy? Why do they not volatilise the earth in a few minutes? I shall not enter on Sir W. Thomson's improvement of this theory, as it involves a different kind of hydro-dynamics from that cultivated in the Essay, but in whatever way we regard Lesage's theory, the cause of gravitation in the universe can be represented only as depending on an ever fresh supply of something *from without*.

Though Prof. Challis has not, as far as we can see, stated in what manner his æthereal waves are originally produced, it would seem that on his theory also the primary waves, by whose action the waves diverging from the atoms are generated, must themselves be propagated from somewhere *outside* the world of stars.

On either theory, therefore, the universe is not even temporarily automatic, but must be fed from moment to moment by an agency external to itself.

If the corpuscules of the one theory, or the æthereal waves of the other, were from any cause to be supplied at a different rate, the value of every force in the universe would suffer change.

On both theories, too, the preservation of the universe is effected only by the unceasing expenditure of enormous quantities of work, so that the conservation of energy in physical operations, which has been the subject of so many measurements, and the study of which has led to so many discoveries, is apparent only, and is merely a kind of "moveable equilibrium" between supply and destruction.

It may seem a sort of anticlimax to descend from these highest heavens of invention down to the "equations of condition" of fluid motion. But it would not be right to pass by the fact that the fluids treated of in this Essay are not in all respects similar to those met with elsewhere. In all their motions they obey a law, which our author was the first to lay down, in addition—or perhaps in some cases in opposition—to those prescribed for them by Lagrange, Poisson, &c.

It is true that a perfect fluid, originally at rest, and afterwards acted on only by such forces as occur in nature, will freely obey this law, and that not only in the form laid down by Prof. Challis, in which its rigour is partially relaxed by the introduction of an arbitrary factor, but in its original severe simplicity, as the condition of the existence of a velocity-potential.

But, on the one hand, problems in which the motion is assumed to violate this condition have been solved by Helmholtz and Sir W. Thomson, who tell us what the fluid will then do; and, on the other hand, Professor Challis's fluid is able, in virtue of the new equation, to transmit plane waves consisting of transverse displacements. As this is what takes place in the luminiferous æther, other physicists refuse to regard that æther as a fluid, because, according to their definition, the action between any contiguous portions of a fluid is entirely normal to the surface which separates them.

It is not necessary, however, for us to say any more on this subject, as the Essay before us does not contain, in an explicit form, the equation referred to, but is devoted rather to the exposition of those wider theories of the constitution of matter and the phenomena of nature, some of which we have endeavoured to describe.

HENSLEY'S "SCHOLAR'S ARITHMETIC"

The Scholar's Arithmetic. By Lewis Hensley, M.A. (Clarendon Press Series, 1873.)

THERE is scarcely any subject more carelessly taught than arithmetic; and, if one would wish to ascertain the reason of this, he has merely to glance at the text-books which have been hitherto most commonly employed. Lately, however, several books of some worth have been presented to the public, and for these we are indebted in a great measure to the late Prof. De Morgan, whose "Elements of Arithmetic," published so far back as 1830, is still regarded as the very best handbook for advanced students. It has, nevertheless, some peculiarities—we cannot call them defects—which have pre-

vented schools from adopting it up to the present time as a text-book; it presupposes too much special talent on the part of the teacher, and contains but few of the modern methods of calculation.

Two main points should ever be kept in view in teaching a subject like arithmetic: first, its principles; secondly, the application of these principles to the affairs of life. In our opinion, the former is undoubtedly the more important if the subject be regarded as an instrument of education. For arithmetical principles are, if properly explained, so very readily comprehended, that a beginner is not likely to find a more delightful path along which he may proceed to the extensive domains of mathematics; but, being generally regarded as a mere catalogue of empirical rules and as a means for exercising the memory, arithmetic becomes, not educational, but instructive, an act of drudgery, and of no more real assistance as a branch of education than needlework or spelling. Explain the ordinary system of numeration to a pupil, let him thoroughly understand the meaning of digit-value and of grade-value, and he will then require but little deep thought, though it will be excellent mental training, to find out for himself the reasons of the four simple rules with respect both to integers *and decimals*. Or, in some cases, let him construct a rule for himself. We do not remember to have ever seen what could fairly be called an arithmetical rider; ordinary problems are not riders, for they are scarcely more difficult than a geometrical theorem with the position and letters of the figure altered. The teacher would occasionally be called in to assist at these exercises; but assistance sought for is far more valuable than that which is spontaneously proffered, and its effect more lasting. Mr. Hensley's "Scholar's Arithmetic" is one of the very few books in which we find decimals discussed in their proper place; indeed it is difficult to understand how this branch of the subject can be logically postponed till a later period if our system of numeration is rationally explained, as of course it should be, at the very commencement of the course.

Pursuing the subject systematically, the pupil should be introduced next to other systems of numeration; and should have at least a little practice in such complex contrivances as long measure and troy weight. Certainly the contrast would be abundantly sufficient to mould any young rational being into a most ardent advocate of the metric system. But we cannot say that Mr. Hensley brings out so strongly as perhaps he might the vast difference between the two methods; his chapter on decimals, treating as it does of conceptions and quantities almost unknown to the great majority of British pupils, is somewhat too abstract. Yet we are glad to recognise in him an outspoken adherent of a universal decimal system, and he seems to look with becoming contempt upon our insular stupidity in fondly cherishing our marvellous weights and measures.

Fractions and proportion are the only other important branches of elementary arithmetic; and, when these are mastered, not only is the attainment of a first-rate knowledge of mental and commercial arithmetic a matter that requires merely time and practice, but algebra becomes thereby most highly attractive as a now comprehensible generalisation, and geometry more alluring even to the unmathematical pupil.

The above-mentioned fundamental divisions and their applications to business, the reader will find fully and ably discussed in the "Scholar's Arithmetic"; and Mr. Hensley has wisely interspersed these all-essential chapters with a few on short methods of calculation, processes of verification, engaging problems, and other similar topics which usually attract the attention and excite the interest of a thoughtful student. There is a short though very lucid chapter on involution and evolution; but, as Mr. Hensley remarks in his preface, he has intentionally passed over subjects which are most easily explained algebraically. There are also more than thirty pages of examination papers from various sources, over and above the numerous examples scattered through the book, as well as a short though sufficient index and glossary. The book is perhaps rather too bulky, and in parts very unequal as regards the difficulty of adjacent sections; but these are trivial failings which will not interfere with its use in schools, and we feel no hesitation in pronouncing it to be one of the most attractive educational works that have appeared on this subject, and it will doubtless be of very great assistance to every earnest teacher.

TEMPLE ORME

OUR BOOK SHELF

The Human Mind; A System of Mental Philosophy for the General Reader. By James G. Murphy, LL.D., Author of Commentaries on Genesis, Exodus, and Leviticus. (Belfast: William Mullan.)

THIS book shows that its author possesses at least one common characteristic of mental philosophers, namely, an inordinately good opinion of his own ability. And, lest the reader should not discover for himself what Prof. Murphy has actually done in psychology (which might happen), he is explicitly told in the preface that, while building on the foundations laid by Reid and Hamilton, Prof. Murphy has, in his own opinion, produced a work which he can venture to submit to "the mental philosopher, as a somewhat nearer approach to the real character of the mind than that of Reid, the founder, or even Hamilton, the lucid and eloquent expositor and defender, of the true system of mental philosophy." Another recommendation put forward in the preface is that this treatise is "among the briefest of those that have gone over the whole field of the mind. Perhaps, we cannot tell. But to us the marvel is that the book should have ever come to an end. We have made several honest attempts to read portions of the respectable looking volume, but have never been able to get beyond a few sentences; for we felt as if launched on a shoreless ocean where we might sail on and on, or round and round for ever, and we could not keep our eyes open on the prospectless outlook. We fear some of the mental philosophers, to whom the book is submitted, will not give it very earnest consideration. What seems to be a main object with Prof. Murphy, and which is, as it appears to us, rather inconsistent with a scientific treatment of the phenomena of mind, is to establish the existence and discover the attributes of Deity. But there are few readers, we should think, who will find much interest or pleasure in his mode of handling this part of his theme. There is not a little of the irreverent jargon with which metaphysical theologians have so often shocked all truly religious people. Here, for example, is a reflection that ought perhaps to leave no doubt as to the honesty of the Almighty, whatever other effect it may have on a religious mind: "He is the Creator of all actual things, which are therefore already His own by an absolute and indefeasible right. He has therefore no temptation to take that which does not belong to Him."

S.

Second Report of the Winchester College Natural History Society. Second and Third Years. (Winchester: J. Wells, 1873.)

THIS Report contains a record of the doings of the Society from May 1871 to February 1873, and is thoroughly encouraging, and certainly a great contrast to the Reports of the two other public schools recently noticed in these pages. The Winchester Report proves that, by judicious management, a School Natural History Society may be made to yield most gratifying results.

The present Report for the two last years, although its record of the earlier papers is incomplete, shows that the Society has been fully alive, and has been growing quietly and steadily, and doing real and satisfactory work. The numbers of the Society are not at this time actually full. But it appears that the elder half of the members are nearly all of them real workers, and it is hoped that the younger half are learning to be the same. It is of more consequence, as the Preface rightly says, that those who belong to the Society should be working members, than that its numbers should be swelled by names. The meetings of the Society have been well attended, and there has been apparent an increasing appreciation of the opportunities afforded by the meetings for showing and seeing objects of interest, as well as for reading and hearing papers.

It is satisfactory to see that old members take an interest in the society after leaving school, several of them contributing valuable papers.

In general, however, we are extremely glad to see, the papers have been those of actual members, and the Society may well feel satisfaction at the increasing readiness, ability, and completeness shown by the leading members in supplying papers at its meetings. The papers which have been read by the Secretaries, Hall, Goddard, and Forbes, may, perhaps, the Preface says, and we think justly, be specially remarked, as combining ability with knowledge based upon personal observation. It is in these papers that the growth of the Society's work has been chiefly seen, and in which its main value consists.

The collections belonging to the School have been considerably increased. The cabinets attached to the Moberly Library now contain about 4,000 specimens, and more are waiting to be mounted and added.

Among the "desiderata" the Preface mentions the following, in case old Wykehamists, or other friends of the School, may be able and willing to supply them:—In Entomology, specimens of Notodontidæ and Pyralides, amongst Lepidoptera; and of any other orders than Lepidoptera. In Conchology, recent Brachiopoda, and Pteropoda. In Geology, Fossils from any of the Primary Formations, Wealden Beds, Red Crag, and Coralline Crag.

The Report contains a number of very interesting papers, mostly by Messrs. E. H. Goddard, W. A. Forbes, and C. S. Rayner, evidently three of the most industrious members of the Society: all the papers are evidence of original observation and independent thought on the part of the writers. The first-mentioned contributes the following papers:—"Hymenoptera," "Botany and Entomology" (in which the localities in the district are indicated in which the collector will reap the best harvest of flowers and butterflies), and one on "Gall Insects." Mr. W. A. Forbes contributes papers on "Coleoptera," "British Reptiles," and "Mimicry and Protective Resemblance." Mr. Raynor contributes a useful paper "On the Different Methods of obtaining Lepidoptera," and a very careful and interesting one "On the Different Modes of Concealment and Defence practised by Insects." The Report also contains a paper on "The Diamond Fields of South Africa," sent by Mr. E. A. Hall. Appended are very full and carefully compiled Botanical, Entomological, and Geological Lists. We hope the next Report will contain a list of the local Fauna, which it is proposed to form.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.]

Perception and Instinct in the Lower Animals

I HAVE waited some time in the expectation that some of your readers would have asked Mr. Wallace a very obvious question with regard to the incident he adduces of a dog finding his master five months after having been lost, and in a house which the latter "had not contemplated going to or even seen before the loss of the dog." (NATURE, vol. viii. p. 66.) In seeking to account for this thoroughly authentic and highly remarkable case, Mr. Wallace observes: "Could it have obtained information from other dogs . . . . ? Could the odour of persons and furniture linger two months in the streets? These are almost the only conceivable sources of information; for the most thorough-going advocates for a "sense of direction" will hardly maintain that it could enable a dog to go straight to his master, wherever he might happen to be." Now, there is yet a third supposition open to us, and it is one which, in the absence of information, is certainly the most probable. Can Mr. Wallace's friend remember whether he had been walking in the vicinity of his new house during the day upon which the dog returned? *i.e.* can he be sure the dog did not trace his footsteps? That a keen-scented terrier is able to distinguish and to follow his master's track in a public thoroughfare, however densely it may be crowded, I know from the success of searching experiments.

With regard to dogs communicating information to one another, I may mention that I have often observed them doing so. According to my experience, the dogs must be much above the average in intelligence, and the gesture they invariably employ is a contact of heads with a motion between a rub and a butt. It is quite different from anything that occurs in play, and is always followed by some definite course of action. I must add, however, that although the information thus conveyed is always definite, I have never known a case in which it was complex—anything like asking or telling the way being, I believe, quite out of the question; so far, at least, as this action is concerned. One example will suffice. A Skye terrier (not quite pure) was asleep in the room where I was, while his son lay upon a wall which separates the lawn from the high road. The young dog, when alone, would never attack a strange one, but was a keen fighter when in company with his father. Upon the present occasion a large mongrel passed along the road, and, shortly afterwards, the old dog awoke and went sleepily down stairs. When he arrived upon the door-step his son ran up to him and made the sign just described. His whole manner immediately altered to that of high animation, and, clearing the wall together, the two animals ran down the road as terriers only can when pursuing an enemy. I watched them for a mile and a half, within which distance their speed never abated, although the object of their pursuit had not, from the first, been in sight.

As the instinct question seems to have come to a close it is desirable to observe that the only outcome of its discussion has been to intensify the previous belief in the existence of some unexplained faculty, which may be provisionally termed a sense of direction. Mr. Wallace, in his general reply, avowedly ignores all those cases adduced by your correspondents in which his theory cannot possibly apply; *e.g.* dogs describing the third side of a triangle, or returning by land whence they had been taken by sea. He says: "Several of the writers argue as if I had maintained that in all cases dogs, &c. find their way, wholly or mainly, by smell; whereas I strictly limited it to the case in which their other senses could not be used" (vol. viii. p. 65). Now, whether or not Mr. Wallace originally intended his letter to raise the general issue as to the presence in dogs of a sense of direction, this has certainly been its effect, so that the instances he here refers to are not in any way beside the question which immediately arose. I have much too high an esteem for Mr. Wallace to say anything that might lead to a discussion with him, but it is evident that these remarks have no such tendency; for, if he admits, as he candidly does in the sentence just quoted, that his theory cannot apply to all cases, it necessarily follows that, even could he prove it to be true in some, the fact, although of considerable psychological interest, would leave the question as to a sense of direction just where it was before.

It should be borne in mind that dogs are not the only animals

in which this sense appears to be present. It is popularly believed to occur in members of at least two orders of Insects, viz. white ants and bees, but I am not aware that any authentic cases have been recorded. Horses and cats seem to possess it in a high degree, and sheep must either have wonderful memories, or owe their return, in numerous cases, to the faculty in question. Still more wonderful, if we deny them this faculty, must be the memory of migratory birds, some of which return, after months of absence and over thousands of miles, to the same nests in successive seasons. If we allow them this faculty it is not, from analogy, improbable that migratory mammals and even fishes are likewise endowed with it. The most conspicuous example, however, is perhaps that afforded by carrier pigeons. To take one case: two or three years ago some of these birds were flown from the Crystal Palace to Brussels, and it stands, if I remember correctly, upon the authority of Mr. Tegetmeier, that they arrived within a few minutes of a telegram despatched from the Palace at the moment they were liberated. Now, in this case, even the extravagant supposition sometimes made that carrier pigeons are guided by the sight of their destination is excluded, for, as these birds are not high-flyers, the curvature of the earth between London and Brussels would prevent them from seeing the latter. And, even if we imagine that these particular pigeons occasionally towered to obviate this difficulty, yet the curvature of the intervening clouds would have imposed another quite as effectual.

There is still one important point which has not been noticed during the discussion of this subject. We possess indications that this sense of direction, like other mental capacities, admits of cultivation by exercise, and, indeed, that it may remain altogether latent and useless until thus developed. If these indications represent generalities we have at once an adequate explanation of the apparently capricious manner in which this faculty occurs.* As this communication is already too long, I shall here be brief.

It is, I believe, a recognised doctrine among fanciers that carrier pigeons, however purely bred, must be educated by flying short distances before they can be depended upon for long ones. I remember having myself lost a valuable bird by flying him, for the first time, at a distance of 500 yards from his nest. Although in full view of it he became utterly confused, taking long flights in various directions, and ultimately went straight out to sea.

Here is an analogous case in a mammal:—I kept a terrier, of highly intelligent parentage, enclosed in a yard with high walls from the time of its birth until it was eighteen months old, and then took it out for the first time, along the sea-shore. The experiment elicited several facts of psychological interest, and one of them has bearing upon the present subject. Part of the coast over which we went and returned was rough with large shingle, and the terrier's locomotive power being very limited, it was unable, on the homeward journey, to keep up with my pace. Desiring to see what it would do if left alone, I continued for half a mile, and waited to see it come up. As it did not do so, I returned, and found that the animal had actually reversed its direction and gone fully a quarter of a mile from the place where I had left it. After having been taken out short distances seven or eight times, it was inadvertently lost in a neighbouring wood. Now, it had only been in the wood once before, yet its appreciation of direction had made so great an advance that it returned an hour afterwards. As this terrier never evinced any disposition to track footsteps, I do not think its return was due to scent. Anyhow, in a few weeks it became an inveterate wanderer, roaming over the country far and wide. GEORGE J. ROMANES

Dunskaith, Ross-shire, July 7

* In connection with these points compare the suggestive remarks of Mr. Darwin, contained in the two concluding paragraphs of his article on Instinct (NATURE, vol. vii. p. 418).

Comte on the Survival of the Fittest

MR. JEVONS called attention some time ago to the desirability of preparing a list of past thinkers and writers who have held, in strength or weakness, the doctrines of Darwin and Spencer. Mr. Darwin has himself named a few of those authors, and Prof. Haeckel has extended the number. Recent communications in NATURE show that the list is as yet incomplete. In reading Comte's "Cours de Philosophie Positive" a few years ago, I was impressed with the general similarity of certain doctrines therein stated with some of Darwin's theories. Referring recently to the 42nd lesson of that course (t. iii.)—"Considérations générales sur la philosophie biotaxique," I find that Comte, in reviewing the Lamarck-Cuvier controversy, says:—

"Toute la célèbre argumentation de Lamarck reposait finale ment sur la combinaison générale de ces deux principes incontestable, mais jusqu'ici trop mal circonscrits: 1°, l'aptitude essentielle d'un organisme quelconque, et surtout d'un organisme animal, à se modifier conformément aux circonstances extérieures où il est placé, et qui sollicitent l'exercise predominant de tel organe spécial, correspondant à telle faculte devenue plus nécessaire; 2°, la tendance, non moins certaine, á fixer dans les races, par la seule transmission héréditaire, les modifications d'abord directes et individuelles, de manière à les augmenter graduellement á chaque génération nouvelle, si l'action du milieu ambiant persévère identiquement. On conçoit sans peine, en effet, que, si cette double propriété pouvait être admise d'une manière rigoureusement indéfinie, tous les organismes pourraient être envisagés comme ayant être, à la longue, successivement produits les uns par les autres, du moins en disposant de la nature, de l'intensité, et de la durée des influences extérieures avec cette prodigalite illimitée qui en coûtant aucun effort à la naïve imagination de Lamarck." (1st ed. "Cours de Philosophie Positive," t. iii. pp. 560 and 561.)

Modification and heredity are here strongly asserted, and the conditions of unlimited transformation as strongly sketched. In continuance of the same argument, Comte, on p. 563, objects to Lamarck's hypothesis, of which he thought very highly as a logical effort:—

"Qu'il repose, ce me semble, sur une notion profondément erronée de la nature générale de l'organisme vivant. Sans doute, chaque organisme determiné est en relation nécessaire avec une système egalement déterminé de circonstances extérieures, comme je l'ai établi dans la quarantième leçon. Mais il n'en résulte nullement que la première de ces deux forces co-relatives ait dû être produite par la seconde, pas plus qu'elle n'a pu la produire: il s'agit seulement d'un équilibre mutuel entre deux puissances hétérogènes et indépendantes. Si l'on conçoit que tous les organismes possibles soient successivement placés, pendant un temps convenable, dans tous les milieux imaginables, la plupart de ces organismes finiront, de toute nécessité, par disparaître, pour ne laisser subsister, que ceux qui pouvaient satisfaire aux lois générales de cet équilibre fondemental: *c'est probablement d'après une suite d'éliminations analogues que l'harmonie biologique a dû s'établir peu à peu sur notre planète, où nous la voyons encore, en effet, se modifier sans cesse d'une manière semblable.* Or, la notion d'un tel équilibre général deviendrait inintelligible et même contradictoire, si l'organisme était supposé modifiable à l'infini sous l'influence suprême du milieu ambiant, sans avoir aucune impulsion propre et indestructible."

The struggle for existence and the survival of the fittest or natural selection are here acknowledged. What is more, the fact that the eliminations due to unfitness for the environment or medium have produced and is producing biological harmony, is pointed out. I have not met with any passages outside of the writings of the new school, which are more explicit than these, though it must not be understood that their author was a transformationist. The preface to the volume in which this occurs is dated "Paris, le 24 Février, 1838." In his general table appended to the sixth volume of his work, Comte says that the Leçon from which these extracts are taken was written between the 9th and 15th of August, 1836. J. D. BELL

New York

The Glacial Period

CAN you inform me if anyone has suggested the following explanation of the existence of the glacial period? And is the explanation I am about to offer a possible one? I put the question in all diffidence, for I have not carefully studied the theory of heat: you must therefore regard any utterance of mine on the subject as merely "a random arrow from the brain." Well, then, it seems to me that the quantity of heat given out in a unit of time from a unit of surface of an intensely heated globe, such as the sun, does not follow the law of radiation of bodies moderately heated. What I mean is this:—It is quite possible that at a time when the sun's mean temperature was higher than it is now, his rate of radiation might have been less; the quantity of heat emitted by him in a unit of time less than it is now. For since his chromosphere must have been thicker, and his solid or fluid nucleus somewhat less in diameter, I suppose that the radiation of the nucleus must have been more retarded by the

chromosphere than is at present the case. It is true, that owing to the increased pressure at the surface of the nucleus due to a thicker chromosphere, the temperature there may have been a little higher; but I do not think that difference would make up for the increase in absorption of the chromosphere.

Assuming then that the sun gives out more heat now in a given time than he did during the glacial period, and that the earth had already so far cooled down that her surface was not sensibly more warmed by internal heat than it is in our own epoch, the mean temperature of the earth's climate would have been lower, and the sea-level line of perpetual snow nearer the Equator in both hemispheres; and glaciers would have covered vast tracks of country which are now denuded of them.

Again, let us go back some millions of years in the world's history, till we arrive at the carboniferous period. The sun then would probably be emitting less heat than even during the glacial period; but the earth would not have cooled down to such an extent, and her internal heat would be sensible at the surface. The mean climate of the globe would have probably been warmer then than it is now, and the temperature more equally distributed, depending not so much on solar as on terrestrial radiation. This being supposed, the vegetation of England and India in those days must have presented less difference than what we find at present. Does the flora of our English and Indian coal-beds support or upset this conclusion? Can any of your correspondents answer this query, or set me right if I am wrong in my hypothesis of solar radiation?

Hampstead, July 22 J. H. RÖHRS

P.S.—Is there any good mathematical treatise on heat, English or French, up to the latest information on the subject? Can you or any of your correspondents recommend me such a treatise?

Telescope Tube for Celestial Photography

I HAVE not yet seen any satisfactory plan suggested of getting over the difficulty experienced in celestial photography by the expansion and contraction of telescope tubes, by changes of temperature in metal tubes.

I therefore venture to suggest the following plan, which may be so arranged as to keep the object-glass and camera-slide *exactly* the same distance apart, and so keep the true focus when once found. The arrangement would have to be modified according to the metal of which the tube is made, but taking a brass one (the most common), with the camera attached to the eyepiece-slide, the correction will be effected by attaching to the main tube, near the eyepiece, two zinc rods the length of the main tube, upon which they must rest loosely; to the free ends of these, near the object-glass, attach a rod of iron extending to the eye-tube; let this iron rod be attached to the eye-tube when the sensitive-plate is exactly in focus; any change in temperature will then have no effect on the focus, for the expansion and contraction of the three metals will keep the distance from object-glass to sensitive-plate constant. All who have worked with a telescope giving sharp definition, will know that this is not an unnecessary precaution, as it may seem to some.

Sydney Observatory, June 14 H. C. RUSSELL

Colour of the Emerald, etc.

I HAVE to beg "A. H." to refer again to NATURE (July 24) p. 254, col. 1, line 23, where he will find it stated that "the emeralds employed were canutillos from Santa Fé de Bogotá. Their specific gravity was 2·69." It is evident, therefore, that they could only be the green silicate of alumina and glucina.

The green sapphire, known also as the "oriental emerald," is the rarest of all gems; and Mr. Harry Emanuel, in his work, "Diamonds and Precious Stones," speaking of it says, "In the whole course of my experience I have only met with one specimen." Its specific gravity would at once distinguish it from the true emerald.

The Beryl A. was colourless, opaque, and had a specific gravity of 2·65. GREVILLE WILLIAMS

INSTINCT, PERCEPTION, AND REASONING POWER OF ANIMALS

THE correctness of the following facts, bearing on the above question, I can warrant:—

A beautiful greyhound bitch in my possession had puppies, and I gave one of them, about a month old, to a friend of mine who was also living in Montpellier at that time. Some few days subsequently, on going to call at my friend's house, I took the greyhound with me. She appeared delighted at finding her puppy again, and expressed her strong feeling by lavishing on it, in her own way, the most tender marks of affection. After a few days I paid a second visit to my friend (unaccompanied by the greyhound), when he informed me that, in consequence of the earnest request of one of his friends, he had been induced to give him the puppy, which had thus been removed to a considerable distance. I returned home, and on my arrival was struck with the peculiar manner in which the animal met me. There was nothing of her usual expression of delight—no barking, no jumping to and fro—but she met me with a serious and thoughtful look, and began slowly to smell my clothes in different places, with the most earnest perseverance. Nor was she content with a mere cursory effort to discover the particular object, whatever it was, which, no doubt, she had in view; but she continued the same course of proceeding for at least a quarter of an hour, in fact, till I found it quite necessary to bring it to a close.

From the above statement of the conduct of the animal, the impression on my own mind was that I must have carried away from my friend's house some subtle effluvia, which tended to bring back to the mother the recollection of her puppy. And this caused me some additional surprise, inasmuch as greyhounds are possessed of great keenness of sight, but are generally considered as rather deficient in their power of smelling. The conclusion is still more remarkable. During the space of about two years I usually paid my friend a visit twice a week, and on every occasion, on my return home, the greyhound would invariably go through the same ceremony. At length the proceeding became altogether so striking that it was quite unnecessary for my wife and family (perhaps from a little innocent curiosity) to ask, "Where have you been?" They could save themselves the trouble of a question and say "I see that you have been calling on your friend."

My cousins were residing in a small village about thirty kilom. from Montpellier, and on one occasion, when I was going to spend some days with them, I took, for the first time, my greyhound with me. It so happened that not far off there was a hound bitch that belonged to one of my cousins' neighbours, and between these two animals (from the beginning of my short stay) there arose the deepest hatred and animosity, and conflicts of the most ferocious kind were matters of daily, almost hourly, occurrence. Time altogether failed in producing any better feeling between them, and to the end of my visit each was ever ready and anxious to try their strength whenever the opportunity offered. In the course of the following year I paid a second visit to the same place, accompanied by my greyhound, and about three-quarters of an hour before I reached the village the animal, as if struck with a sudden idea, rushed forward at her full speed, and all attempts to call her back proved quite ineffectual. On reaching the village I found that a terrible encounter had already taken place between the two heroines, who were on the point of renewing the attack after a temporary cessation of hostilities.

The following anecdote relating to the same greyhound seems to prove that these animals may sometimes exhibit a higher standard of reasoning power than according to general opinion they possess.

I was passing some days in the country with my aunt, who had a middle-sized spaniel bitch, of a somewhat sullen and treacherous temper. This spaniel observed, with an evident feeling of jealousy, that my greyhound was making herself quite at home in my aunt's kitchen, and whenever she had a favourable opportunity, without

exposing herself to too much danger, she never failed to give an angry bite to her unsuspecting rival, and immediately to rush for shelter under a kneading-trough, from which position my greyhound was unable to dislodge her.

After a short time the spaniel had puppies, and she was placed with two of them in a corn-loft, over the kitchen, from which there was a door which led to it by a flight of stairs; the door was usually kept closed in consequence of the known animosity between the two rivals. For some days the new mother, entirely occupied with the care of her little ones, did not descend to the kitchen, and my greyhound occasionally showed a strong desire to go up to the loft and see what was going on there. When the puppies were about seven or eight days old, their mother began to re-appear in the kitchen, and to observe towards the greyhound the same line of conduct, with the exception only of an appearance of increased hatred. At length, on one occasion, when the spaniel was eating her dinner, and the corn-loft door happened to be partly open, my greyhound, taking advantage of the opportunity, sprang up the stairs of the loft. I observed the circumstance, and on calling her down she immediately obeyed, and made her appearance before me with a look of perfect satisfaction. About an hour afterwards my aunt's husband, on going to the loft, found both the puppies dead, without the least mark of external violence, and he was at a loss to imagine what could have caused their death. For myself I had an impression on my own mind as to the cause of death, but I did not consider it necessary at the time to mention it to others. I opened the bodies of the puppies, and found my opinion confirmed. The skin was externally sound through its elasticity, but the fangs of the greyhound had done their work, and the liver had been bruised into a kind of marmalade—exactly in the same manner as the greyhound usually crushes the liver of the hare or the rabbit, which, literally speaking, are no sooner seized than dead.

In November last, when I was staying with my cousin, I was much interested in observing the proceedings of various kinds of poultry in a field almost contiguous to the house. There were six or seven young guinea fowls, ducks, hens, &c., and also a pair of old guinea fowls, which kept always by themselves, and continued running to and fro with that perpetual restlessness which is natural to them. In the midst, however, of their wildest proceedings they always appeared to keep an eye on the young guinea fowls, and whenever any of the other poultry happened to approach the spot where they were, the old guinea fowls invariably ran with all speed and drove them away. Two large hens alone seemed to be exempt from this rough treatment, and to have full permission to come near the young guinea fowls or not, just as they liked. One of the hens, in particular, seemed to enjoy some special privileges, and in case of any apparent danger, there was some immediate proof of care and protection on the part of the old guinea fowls.

The above circumstances excited my curiosity, and I obtained the following explanation:—

One of these hens had hatched some guinea fowls' eggs, but after three days had neglected to perform the new functions incumbent on her, and had left the young brood to themselves. Fortunately, the other hen, which had previously exhibited the well-known symptoms of the fever of incubation, adopted the deserted young ones, and had nursed them with the greatest affection till they were able to take care of themselves. The old guinea fowls, it appears, had observed all these circumstances, and had retained a grateful recollection of them.

Under the roof of a small tower at my father's house in the country, a large number of sparrows (consulting their own convenience, rather than that of others), had established their nests; but in consequence of the extensive injury caused to the corn-fields by their depredations at harvest-time, my father, with a view to lessen their number, gave direction that all the nests should be removed, and thus, by this wholesale order of destruction, about 80 nests with 366 eggs suddenly disappeared. Their fondest hopes being thus blighted, and the expected fruit of all their labour nipped, as it were, in the bud, the sparrows betook themselves to noisy meetings, and, in their own way, to expressions of anger and resentment. This proceeding continued for at least a week, after which they dispersed, and went in search of some other less dangerous shelter for their future progeny. In the following year some sparrows, which had built their nests under other buildings of our country house, and which had been left unmolested, returned to them; but from that time to the present day (forty-eight years) I can safely affirm that no sparrow has ever rebuilt her nest under the roof of the tower. The singular facts of the case are these: the sparrows decidedly object and decline to build any more nests under the roof of the tower, but they are quite willing to avail themselves of the shelter of the position during the severe nights of the winter season.

Montpellier DR. PALADILHE

THE GROWTH OF SALMON

SINCE the time of Magna Charta it has been an object, directly or indirectly, on the part of the Legislature, to protect the supplies of salmon with which our rivers used to be so abundantly stocked: but notwithstanding the laws which have at various times been enacted, this fish gradually became scarcer till, in 1861, all the old laws were repealed, and fresh and more stringent regulations made for protecting and increasing our salmon supplies. In addition to the fostering care which is bestowed, under the Salmon Fishery Acts of 1861 and 1865, on the fish in the rivers, means have been adopted to artificially rear salmon, so as to increase their numbers more rapidly than could be done in the ordinary course of nature. Mr. Frank Buckland has been the pioneer of this system of artificial breeding of salmon and trout, and the experiments and operations which have been carried on during the last few years have thrown great light on the hitherto unknown habits of this "king of fish."

Anyone who looks into the fishmongers' shops just now can see what a clean, fresh-run salmon, ready for cooking, is like—a silvery, plump creature, whose "lines" are made for speed in water, and whose graceful curves give the completest idea of vigour and strength in stemming a rapid current of water.

But very few people, probably, know what sort of an appearance this beautiful fish presents in its infancy. Hidden away during that period in the upper waters of our salmon rivers, and ultimately in the depths of the sea, it is lost to sight till it grows large enough to be taken by the salmon nets; and until lately very little was known of its natural history, or of its habits, though the experience of the last few years has revealed many interesting facts concerning the development of this fish, through the egg, fry, smolt, and grilse stages, till it becomes a full-grown salmon.

Fig. 1 represents the egg—natural size—of a salmon just laid. Each female salmon carries, on an average, 800 to 900 of such eggs to every pound of her weight. They are generally of a pinky opal colour, elastic to the touch, covered with a soft horny membrane, with a minute opening through which a particle of the spawn—the soft roe—of the male fish enters, and the egg is fertilised. From this moment the young fish gradually develops, under the influence of the cold running water. At the end of about 35 days—more or less according to the temperature, which should be about 40°—two little black specks can be seen, as at Fig. 2, which are the eyes of the embryo fish; the vertebræ may be discerned in the form of a faint red line, and a small red globule

which shortly afterwards appears, represents the vital organs of the embryo fish.

At the end of about 80 to 100 days from the deposition of the egg the fish has so increased in size that it bursts the "shell" and makes its *début* in the form represented at Fig. 3. The sac or umbilical vesicle attached to the under part of the fish contains a secretion resembling albumen, which affords nourishment to the infant fish for the first six weeks or so of its existence. By that time it is quite absorbed, and for the first time we see a perfect

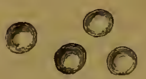

FIG. 1.

FIG. 2.

Fig. 1.—New-laid Salmon Egg. Fig. 2.—Egg after about 35 days.

fish, Fig. 4, with its fins, gills, and scales, which have hitherto been present, but imperceptible except under the microscope, fully formed: and now the young salmon begins to feed. His growth is not very rapid for some months, the lines *a b c* representing the average length of a salmon at 2, 3, and 4 months old. At 2 years old the fish is about 9 to 12 inches long.

As soon as they are large enough and strong enough, the "smolts," as they are now called, descend to the sea; here they are lost sight of until they return up the river as "grilse." The actual duration of their stay in the sea is not yet known, from one to three years being variously estimated as the probable length of time. The object of this migration to the sea is to find the food which is necessary for the secretion of the fat of the fish, who lives on the *Infusoria*, smaller fish and crustaceans, and the spawn of sea-fish which abound in our seas. The length of their stay in salt-water is regulated, no doubt, by various circumstances, and is not the same in every case. When the salmon has laid up a sufficient supply of fat in its body and on its pyloric appendages, which are a wonderful provision of Nature for the secretion of an amount of fat sufficient to supply it during its sojourn in fresh waters, it ascends the river, its roe or spawn developing as it ascends; till, about Christmas-time, or sometimes earlier, it reaches the shallow headstreams of the river, in the gravelly beds of which it deposits its eggs, returning immediately afterwards to the sea, no

FIG. 3.—Fish coming out of egg.

longer in the bright, plump, muscular condition in which it ascended, but a lean, lank, ugly, wounded beast, which one would hardly recognise as *Salmo salar*. Fig. 5 represents the head of a "kelt," as those salmon are called which have newly spawned. The curved projection, or hook, on the lower jaw, is a cartilaginous membrane, the use of which nobody knows. The fish is in a very weakly condition, as his fat is gone, and he perhaps assumes this appearance to frighten other animals, which might otherwise be tempted to attack him. The drawing is taken from the photograph of a salmon, weighing 20lb., which was found dead on the banks of one of our Welsh rivers.

This fish, had it survived, would have returned to sea, recovered its fat, and presently come back worth 2*l.* or 3*l.*, whereas, by dying in this condition, it was worth nothing. It had, however, done its duty by depositing perhaps 16,000 eggs. Only a very small percentage, however, of the eggs laid ever become adult fish. Floods wash them out of their gravel nests; ducks, and other birds, eat them; beetles and various insects attack them; they are smothered with mud, or left high and dry on the shore; the young fish are poisoned by pollu-

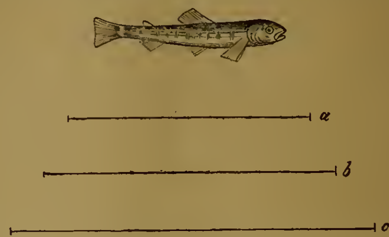

FIG. 4.—Young Salmon six weeks old. *a*, *b*, *c*, size of salmon at two, three, and four months respectively.

tions, or diverted into mill leats and canals, and so lost; trout eat them wholesale; in fact the whole of their earliest existence is a very living death, and it is a wonder, with all the ordeals they have to pass through, that we have any salmon left. To kill them legitimately for food for ourselves is bad enough, and we ought to do all we can to protect them when young.

In the artificial system of breeding salmon the adult fish are caught just as they are on the spawning beds, and the eggs taken from them; the ova and milt are properly mixed together, and the eggs placed in troughs of water so arranged as to imitate as closely as possible the natural conditions necessary for the development and growth of the fish. Properly managed, 90 per cent. of the eggs will hatch out: the young fish are turned into the river when they are about a year old; if they can be kept two years in tanks large enough, with plenty of running water, so

FIG. 5.—Head of a Kelt.

much the better for the prospect of their reaching the sea in safety.

When we can make up our minds to keep all our pollutions out of our rivers, and build "salmon ladders" over all the weirs, so as to give the fish a fair field, and enable them to run up stream unimpeded, then, and then only, shall we see salmon as plentiful throughout the country as it is said to have been in the North a century ago, when apprentices are reputed to have stipulated in their indentures that they should be fed on salmon not more than three days a week. Without this all our efforts to stock our barren rivers with artificially bred fry will prove comparatively unavailing.

C. E. FRYER

THE GLACIAL DRIFTS OF NORTH LONDON

THE landscape memorials of the great glacial period in Britain have hitherto been chiefly looked for by the tourist in the northern and mountainous districts of our island. The vast and wide-spreading products of the same epoch which lie in the lower and more southerly districts of England, as far as the Valley of the Thames, have had to wait longer for their due recognition. In the interval, the Londoner addicted to geologising has been fain to go to Snowdonia, Borrodaile, and the Highlands of Scotland—to the region of perched blocks and terminal moraines—for memorials of the Ice Age within our own coasts. Nor is it to be wondered at that the districts in which glacial action on a grand and cosmical scale was first detected in Britain, and which still afford the more obvious monuments of the glacial period, should so long have monopolised attention. But the time seems now to have come for the drifts of the southern regions to take their proper place in the gallery of glacial phenomena.

So recently have these drifts changed their character in the eyes of geologists that it may be worth while to summarise their history, and indicate the conclusions which have now been arrived at with regard to them as well as one or two important moot points which will perhaps remain doubtful for some time to come.

It seems only yesterday that the glacial drifts of the lower and southern districts of England were looked upon as a mere congeries of rubbish heaps and "diluvium"—chaotic and unintelligible relics of some mysterious and partly hypothetical period. Now, however, these deposits are no longer slighted by geologists. In the hands of one or two earnest workers—notably Mr. Searles V. Wood, jun.—the glacial clays, and sands, and gravels of England are rising into the dignity of a system. The North London glacial drifts may be taken as typical in most respects of the great and wide-spreading deposits which are found in the inland counties most remote from the homes of the old British glaciers.

FIG. 1.—A, Glacial Sands and Gravels. B, Glacial Clay. Unshaded Parts—London Clay.

The Finchley and Muswell Hill drift lying on the northern heights of London overlooking the Thames Valley occupies a position of great geological interest and significance. Muswell Hill figures in the very early annals of the beds which are known to be of glacial origin. In the year 1835, Mr. N. T. Wetherell, of Highgate, made the discovery which has given such repute to the spot. In Coldfall Wood, just beneath the vegetable soil, Mr. Wetherell found one of those strange medleys which geologists were then wont to dismiss as "diluvium." Here, as far south as the Thames Valley, were water-worn fragments of granite, mountain limestone, coal, red chalk—indeed rock-specimens from all the northern formations, with a similarly heterogeneous collection of

fossil remains. Agassiz had not as yet broached the great conception of the glacial period; the diluvium reigned supreme. Year by year more extensive patches of fossiliferous clays and gravels were found adjacent to Muswell Hill. From Finchley and Whetstone an abundance of fossils proper to the chalk and oolite formations was obtained, and whole hampers of belemnites were sent off to Prof. Phillips at Oxford for the purpose of his monograph on that genus. But the drift itself remained an isolated phenomenon. It was left to men of the younger generation to attack a problem as worthy of solution as the problems of Cambria and Siluria.

During the last five or six years, the Finchley and Muswell Hill drift has excited fresh attention. The Great Northern Branch Railway from East End to Finchley has exposed some fine sections, and a body of earnest field-geologists—the Geologists' Association—has been at hand to take advantage of the opportunities thus afforded. In the same period Mr. Wood has published his "Sequence of the Glacial Beds," and the Geological Survey a map of the superficial deposits of the district.

Lying on the hills and plateaux, the North London drifts have a scenic interest. They form noticeable features in the Middlesex landscapes, as may be seen in the accompanying geological map of the district (Fig. 1). The valleys and streams around the plateaux delineate in an instructive manner the extent of the glacial beds, whilst they suggest the action of those meteorological forces which have reduced these beds to their present limits since their elevation above the sea.

But unlike the moraines of Snowdonia and other mountain districts, these much older lower ground accumulations are not, in the view of most English glacialists, the immediate deposits of land ice. Contrary to the beliefs of the Scotch geologists, who would regard them as the equivalents of the Till, they are referred to the era of the great submergence of England beneath the glacial sea. They are the transported material of the submarine terminal moraine. As the ice-foot retired before the submerging sea, it left behind it the *débris* of the rocks it had degraded to be transported by bergs and rafts over the Middlesex of the future.

The glacial deposits at Finchley station, although they conform to the general character of such beds in the south-western counties, have certain features which may prove to be more developed here than elsewhere, and may, at some future time, help to connect these deposits with their more local sources of supply. The preponderance of the characteristic Oxford clay fossil *Gryphæa dilatata* is remarkable, and whilst the chalk and the Oxford clay are the most largely represented, the formations of which the fewest traces are found are the gault and the London clay. Foreign blocks, transported by ice, are generally absent from the district. Blocks of Sarsen sandstone are not uncommon, but it is worthy of notice that they are only found in the drift.

The vast sources of supply for the flint pebbles which abound in the glacial gravels of the district are still represented in the small and local remainders which cap the high ground at Totteridge, and are found at Barnet,

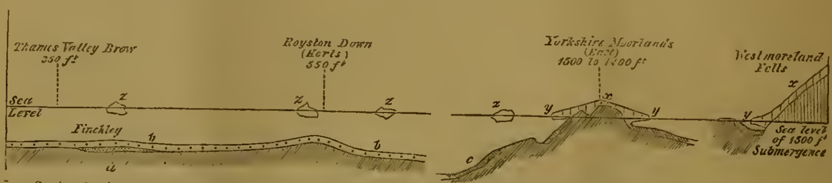

FIG. 2.—Section showing the degree of submergence indicated by the upper Glacial Deposits. References—*a*, The Middle Glacial. *b*, The Chalky Boulder Clay. *c*, The Purple Clay without Chalk. *x*, The Ice Sheet. *y*, The Ice-foot. *z*, Floating Ice.

where these second-hand accumulations of the Lower or Middle Bagshot, disturbed or redeposited, are free from the quartzites of the glacial gravels, and exhibit an unmixed Eocene lineage.

After years of untold labour, which offer a noble example of private enterprise in the cause of geology, Mr. Searles V. Wood, jun., has established the succession of the glacial beds of the east of England and the central counties, which is here given in abstract :—

Post-glacial Beds

I. UPPER GLACIAL.—1. The purple boulder clay of Yorkshire without chalk. 2. The purple boulder clay with chalk. 3. *The Great Chalky Boulder Clay of the South of England* (*e.g.* at Finchley and Muswell Hill).

II. MIDDLE GLACIAL.—*The Middle Glacial Sands and Pebbly Gravels of the South-East of England and the Central Counties* (*e.g.*, the Finchley and Muswell Hill sands and pebbly gravels).

III. LOWER GLACIAL.—The Contorted Drift of Norfolk, the Cromer Till, and the Pebbly Sands of Norfolk and Suffolk (Upper Crag).

A few words further in explication of this sequence will show how wide an area of England is concerned in the deposits with which the Finchley drifts are thus correlated.

The deposit to which the Finchley chalk boulder clay belongs stretches in an intermittent way from the lower Thames Valley to Central Lincolnshire, and from the Eastern Counties of Norfolk and Suffolk to East Staffordshire. The Finchley sands and gravels extend (mostly covered by the boulder clay) over nearly all the three large counties of Norfolk, Suffolk, and Essex, and are present in Herts, Bucks, and Leicester. So there is no insignificant number of geologists, away from the region of the old glaciers, who may study in their own locality the memorials of the great glacial period in England.

Inasmuch as the maps which Nature has laid down in the ground beneath us are historical as well as physical, this sequence introduces us to a series of consecutive events in the earlier history of the great Glacial Period. In the lower glacial the age of Ice begins. In the next deposit we notice a pause in the Arctic conditions which had prevailed. The formation of that characteristically glacial deposit, the boulder clay, was arrested, and the sands and gravels (middle glacial), of milder waters, took its place. Then the Arctic conditions returned, and brought in the chalky boulder clay. At length the higher rocks were brought within the reach of the sea, until the Yorkshire Wolds were submerged, and eventually the Westmoreland fells yielded their *débris* to be spread over the sea-bottom (Fig 2). That the glacial period should have left its memorials so far south in our island as the valley of the Thames, was a matter of incredulity among many geologists, even so recently as ten years since, when Sir Charles Lyell had compelled attention to the Muswell Hill drift in the "Antiquity of Man." That the

drift of the glacial period did not once extend over the counties south of the Thames has yet to be demonstrated, and those geologists who hold that we have already discovered the original southern limits of the glacial clays and gravels in England, have yet to explain the condition of these deposits of the north brow of the Thames Valley, where they are as pelagic in character as they are a hundred miles farther north.

The dwellers in the south of England have thus been compensated for their distance from the bolder region of the old British glaciers, of perched blocks, and terminal moraines. The glacial period has now been brought home, as it were, to their own doors. By the classification of the glacial beds which we now possess, patches of clay and gravel which seemed to have a sporadic and insignificant character are seen to belong to a great and historical series. In the presence of such "diluvium" as that of Muswell Hill, with its astonishing medley of organic remains, it needs no longer to be asked,—

> "What seas receding from what former world
> Consigned these tribes to stony sepulchres?"

We know now that it was an icy sea.

HENRY WALKER

FLIGHT NOT AN ACQUISITION

A FEW weeks ago, when at Ravenscroft (the residence of Lord Amberley), I shut up five unfledged swallows in a small box not much larger than the nest from which they were taken. The little box, which had a wire front, was hung on the wall near the nest, and the young swallows were fed by their parents through the wires. In this confinement, where they could not even extend their wings, they were kept until after they were fully fledged. I was not at Ravenscroft when the birds were liberated, but the following observations were made by Lord and Lady Amberley, who have kindly communicated them to me. On going to set the prisoners free, one was found dead—they were all alive on the previous day. The remaining four were allowed to escape one at a time. Two of these were perceptibly wavering and unsteady in their flight. One of them after a flight of about 90 yards disappeared among some trees; the other, which flew more steadily, made a sweeping circuit in the air after the manner of its kind, and alighted, or attempted to alight, on a branchless stump of a beech; at least it was no more seen. I give the unabridged account of No. 3 and of No. 4 as it stands in the notes made at the time by Lady Amberley. "No. 3 (which was seen on the wing for about half-a-minute), flew near the ground first round Wellingtonia, over to the other side of kitchen garden, past beehouse, back to the lawn, round again, and into a beech tree. No. 4 flew well near the ground, over a hedge twelve feet high to the kitchen garden, through an opening into the beeches, and was last seen close to the ground." The following remarks were added subsequently: "The swallows never flew against anything, nor was there in their avoiding objects any appreciable difference between them and old birds. No. 3 swept round the Wellingtonia, and No. 4 rose over the hedge just as we see the old swallows doing every hour of the day." It remains to add that each of these birds was weighted with a small collar of coloured cloth, put on for the purpose of marking them; and that an old swallow on being set free encumbered by a similar adornment, exhibited the same unsteadiness in its flight.

There is little need to make any remark on the above facts. In proving the flight of birds, and their power of guiding their course through the air in accordance with their sensations of sight, not to be an acquisition, they support the general doctrine that all of what may be called the professional knowledge and skill of the various species of animals come to them by intuition, and not as the results of their individual experiences. With wings there comes to the bird the power to use them. Why, then, should we believe that because the human infant is born without teeth, it should, when they do make their appearance, have to discover their use? The swallow, the first time it is in the air takes care, or rather does not need to take care, not to dash its brains out against a stone wall. Why, then, should we believe man to have no instinctive faculty of interpreting his visual sensations?

DOUGLAS A. SPALDING

BRITISH ARCHÆOLOGICAL INSTITUTE

THE annual meeting of this Institute commenced at Exeter on Tuesday, July 29, the President for the year being the arl of Devon. Many valuable papers were read, and many interesting excursions made in the neighbourhood; the reception by the Mayor, the local authorities, and the inhabitants generally, has been most enthusiastic. The Congress was brought to a close on Tuesday last, and is declared to have been the most successful meeting of the kind ever held. Of the many valuable papers read we give the following by Dr. E. A. Freeman, on "The Place of Exeter in English History."

He remarked that it sometimes came into the mind of an English traveller in other lands that the cities of his own country must seem of small account in the eyes of a traveller from the land which he visited. He spoke of course as an antiquary and not of modern prosperity and splendour. As a rule an English town did not make the same impression as an artistic and antiquarian object as did towns of Italy, Germany, Burgundy, France, or Aquitaine But whilst we had few cities as rich at once in history and art as many of those on the Continent, yet we need not grieve; for whatever was taken from particular districts was added to the general history of our country. Why was the history of Nuremburg greater than that of Exeter? Simply because the history of England was greater than that of Germany, The domestic history of an English town which had always been content to be a municipality, and had never aspired to be a sovereign commonwealth, seemed tame beside the stirring annals of the free cities of Italy and Germany. But for that especial reason it had a value of its own, it had not struggled for the greatness of its own, but it had done its work as part of a greater whole—it had played its part in building up a nation. And the comparison beween the lowly English municipality and the proud Italian or German commonwealth had also an interest of another kind. The difference between the two was simply the difference implied in the absence of political independence in the one case and its presence in the other. The difference was purely external—the internal constitution—history and revolutions—often presenting the most striking analogies. In both might often be seen the change from democracy to oligarchy, and from oligarchy to democracy. In both they might see men who, in old Greece, would have taken their places as demagogues, perhaps tyrants. Exeter had something to tell of Earl and Countess of Devon; Bristol of its half-citizens, half tyrants, the Lords of Berkeley. In the free cities of the Continent we saw what English cities might have been if the royal power in England had been no stronger than that of the Emperors, and if England had therefore split up into separate states like Germany, Italy, and Gaul. In England the constant tendency had been to unity and to make every local power subordinate to that of the king, and it was this that had made the difference between a municipality like Exeter and a commonwealth like Florence. In Exeter reflections of this kind had a special fitness. No city in England had a history which came so near to that of the great conti-

[illegible] cities, none could boast of a longer unbroken existence nor was so direct a link between the earliest and the latest days of the history of our island. None had in all ages more steadily kept the character of a local capital, the undisputed head and centre of a great district. And none had come so near to being something more than a local capital, none had had so fair a chance as Exeter of once becoming an independent commonwealth, the head of a confederation of smaller boroughs, perhaps the mistress of dependent towns and subject districts. It was not then with mere words of form that he might congratulate the Institute on finding themselves at last within the walls of the great city of Western England. They had been to many other places, to York, Lincoln, and Chester, and if Exeter must yield to these in the wealth of actually surviving monuments, it assuredly did not yield to any of them in the historic interest of its long annals. It had, in truth, peculiar interest of its own in which it stood alone amongst the cities of England; she was among cities what Glastonbury was among churches, it was one of the few ties which directly bound the Englishman to the Roman and the Briton. It was the great trophy of that stage of English conquest when our forefathers, weaned from the fierce creed of Woden and Thunder, deemed it enough to conquer and no longer sought to destroy.

Exeter, Isca, Caer Wisc was a city of the same class as Bourges and Chartres. Here was what was found commonly in Gaul but rarely in Britain—the Celtic hill-fort which had grown into the Roman city, which had lived on through Teutonic conquest, and which still, after all changes, kept its place as the undoubted head of its own district. In Wessex such a history was unique; in all Southern England London was the only—and that but an imperfect—parallel. The name carried on the same lesson which was taught by the site. Caer Wisc had never lost its name. It had been Latinised into Isca, Teutonised into Exancester, and cut short into modern Exeter, but through all conquests, through all changes of language, it had proclaimed itself as the city by the Exe. In this respect the continuity of its being had been more perfect than that of most of the cities of Northern Gaul. The name and the site of Exeter at once distinguished it from most of the ordinary classes of English towns. . . .

The first question which now suggests itself was one which he could not answer—when did the city first become a West Saxon possession? When did the British Caer-Wisca, the Roman Isca, pass into the English Exancaster? Of that he could find no date—no trustworthy mention. The first distinct and undoubted mention of the city he could find was in the days of Alfred, where it figured as an English fortress of great importance, more than once taken and retaken by the great king and his Danish enemies. He was as little able to fix the date of the English conquest of Isca as he was to fix that of its original foundation by the Britons. John Shillingford said that Exeter was a walled city before the incarnation of Christ, and though it was not likely to have been a walled city in any sense that would satisfy either a modern or Roman engineer, yet it was likely enough to have been already a fortified port before Cæsar landed in Britain. At all events the first definite mention of it was in the time of the wars of Alfred. But though it was English by allegiance, it was not until two centuries later that it became wholly English in blood and speech. In Athelstan's day the city was still partly Welsh, partly English, each forming a city within a city. To this state of things Athelstan deemed it right to put a stop and to put the supremacy in the chief city of the western peninsula beyond a doubt. Exeter was a port which needed to be strongly fortified, and to be in the hands of none but what were thoroughly trustworthy. The British inhabitants were driven out, and to the confusion of those who say Englishmen could not put stones and mortar together until a hundred and forty years later, the city was encircled by a wall of square stones and strengthened by towers, marking a fourth stage in the history of English fortification. If anyone asked him where the wall of Ethelstan was now he could only say that a later visitor to Exeter took care that there should not be much of it left for them to see. Still there were some small fragments, but suppose not a stone was left, yet as he understood evidence, the fact that a thing was recorded to have been destroyed was one of the best proofs that it once existed. The distinguishing point in this stage of the history of Exeter was this, that it alone of the great cities of Britain did not fall into the hands of the English invaders till after the horrors of conquest had been softened by the influence of Christianity. When Caer Wisc became an English possession there was no fear that any West Saxon prince should deal with it as Ethelfrith had dealt by Deva. When Isca was taken the West Saxons had ceased to be destroyers, and deemed it enough to be conquerors. Thus it was that Exeter stood alone as the one great English city which had lived an unbroken life from pre-English and even from pre-Roman days.

Whatever was the exact date when it became an English possession, it was with the driving out of the Welsh inhabitants under Ethelstan that it became purely English. As such it filled during the whole of the tenth and eleventh centuries a prominent place among the cities of England and a place altogether without a rival among the cities of its own part of the country. Later in the century the fortress by the Exe was the chief bulwark of Western England during the renewed Danish invasions of the reign of Ethelred. It was a spirit-stirring tale to read how the second millennium of the Christian era was ushered in by the record which told how the heathen host sailed up the Exe and strove to break down the wall which guarded the city, how the burghers bore up against every onslaught, and how they withstood the invaders. Exeter was saved, but the unready King had no help or reward for the men who saved it, and the local force of Devon and Somerset had to strive how they could against the full might of the invader, and the devastation of the land around followed at once upon the successful defence of the city. In the next year Exeter became part of the "Morning gift" of the Norman Lady, and Hugh, "The French Churl," as our chroniclers call him, was sent by his foreign mistress to command in an English city, and through his cowardice or treason Sweyn was able to break down and spoil the city. It was not clear whether all the walls were broken down then, but it was quite certain that sixty years afterwards, Exeter was strongly fortified according to the best military art.

After the city's capture by Sweyn nothing more was heard of it during the Danish wars, and the only further knowledge of it between the Danish and Norman invasions consisted of the foundation of the bishopric, and this was accompanied by several circumstances which marked it as an event belonging to an age of transition. It was among the last instances of one set of tendencies, among the earliest instances of another. The reign of Edward the Confessor was the last time (excepting the reign of Edward the Sixth) when two English bishoprics were joined together without a new one being formed to keep up the number. It had happened more than once in earlier times; it happened twice under Edward when the bishoprics of Devonshire and Cornwall were united, and those of Dorset and Wiltshire. But this also was the first instance of a movement for bringing into England the continental rule that the bishopric should be placed in the greatest city of the diocese.

The great ecclesiastical change of the eleventh century had carried him on beyond the great time which

stood out above all others in the history of Exeter, when they might say that for eighteen days Exeter was England. The tale of the great siege he had told elsewhere in full detail, and he would not tell it again now, but the story of the resistance of the western lands and their capital to the full power of the Conqueror, was one that never ought to pass away from the memories of Englishmen. The bravery of the inhabitants formed a tale which, even in that stirring time, spoke more than any other—save the tale of the great battle itself—to the hearts of all who loved to bear in mind how long and hard a work it was to make England yield to her foreign master. But whilst our hearts beat with those of the defenders of Exeter, yet we saw none the less now that it was for the good of England that Exeter fell. A question was here decided, greater than that whether Harold, Edgar, or William should reign—the question whether England should be one. When Exeter stood forward for one moment to claim the rank of a free, imperial city, and her rulers expressed themselves willing to receive William as an external lord, but refused to admit him within her walls as her immediate sovereign, they saw that the tendency was at work in England by which the kingdom of the continent was split up into loose collections of independent cities and principalities, and the path was opening by which Exeter might have come to be another Lubeck, the head of a Damonian house, another Bern, the mistress of the subject lands of the Western Peninsula. Such a dream might sound wild in our ears, and we might be sure that no such ideas were present in any such definite shape to the minds of the defenders of Exeter. But any such designs were probably just as little known to the minds of those who in any German or Italian city took the first steps in the course by which from a municipality, or less, the city grew into a sovereign commonwealth. Historically, the separate defence of Exeter was simply an instance of the way in which, after Harold was gone, England was conquered bit by bit. York never dreamed of helping Exeter, and Exeter, if it had the wish, had not the power to help York. But it was none the less true when we saw a confederation of western towns, with the great city of the district at their head, suddenly starting into life to check the progress of the Conqueror—we saw that a spirit had been kindled which, had it not been checked at once, might have grown into something, of which those who manned the walls of Exeter assuredly never thought. We could hardly mourn that such a tendency was stopped even by the arm of a foreign conqueror. We could hardly mourn that the greatness of Exeter was not purchased at the cost of the greatness of England. But it was worth while to stop and think how near England once was to running the same course as other lands. From the sacrifice of the general welfare of the whole to the greater brilliance of particular members of the whole, we had been saved by a variety of causes, and not the least of them by the personal character of a series of great kings working in the cause of national unity, from West Saxon Egbert to Norman William. The tendency of the patriotic movements in William's reign was to division; the tendency of William's own rule was to union. The aims of the Exeter patricians could not have been long reconciled with the aims of the sons of Harold, nor could the aims of either have been reconciled for a moment with those of the partisans of the Etheling Edgar, or of the Danish Sweyn. We sympathised with the defenders of Exeter, York, Ely, and Durham, but from the moment England lost the one man of her own sons who was fit to guide her, her best fate in the long run was to pass as an individual kingdom into the hands of the victorious rival.

With the subjection of Exeter by William might fairly be ended the tale of the place of Exeter in English history. It was then settled for Exeter that she was to be an English city—no separate commonwealth—a member of the individual English kingdom. But still a city that was to remain the undisputed head of its own district. Its history from this time was less the history of Exeter than the history of those events in English history that took place at Exeter. It still had its municipal, ecclesiastical, its commercial history, but no longer a separate political being of its own. It was no longer an object to be striven for by men of contending nations, nor something that might be cut off from the English realm either by the success of a foreign conqueror or the independence of its own citizens.

In the other sense of the word, as pointing out those events of English history of which Exeter was the scene, the place of Exeter in English history was one which yielded to that of no other city in the land save London itself. It was with a true instinct that the two men who open the two great eras in local history—English Ethelstan and Norman William—both gave such special heed to the military defences of the city. No city in England had stood more sieges. It stood one, and perhaps two more, before William's own reign was ended—indeed before William had brought the conquest of the whole land to an end by the taking of Chester. The men of Exeter had withstood William as long as he came before them as a foreign invader; when his power was once fully established, when the Castle on the Red Mount held down the city in fetters, they seemed to have had no inclination to join in hopeless insurrections against him. When, a year and a half after the great siege, the Castle was again besieged by West Saxon insurgents, the citizens seemed to have joined the Norman garrison in resisting the attack. According to one account they had already done the like to the sons of Harold and their Irish auxiliaries. The wars of Stephen did not pass without a siege of Exeter, in which king and citizens joined to besiege the rebellious lord of Rougemont, and at last to starve him within the towers of which legend was already beginning to speak as the work of the Cæsars.

To pass to later times, the Tudor era saw two sieges of the city, one at the hands of a pretender to the crown, and another at the hands of the religious insurgents of the further West. Twice again in the wars of the next century Exeter passed from the one side to the other by dint of siege, and at the last she received an invader at whose coming no siege was needed. The entry of William the Deliverer through the Western Gate formed the balance—the contrast—to the entry of William the Conqueror through the Eastern Gate. The city had resisted to the utmost when a foreign invader, under the guise of an English king, came to demand her obedience. But no eighteen days' siege, no blinded hostages, no undermined ramparts were needed when a kinsman and a deliverer came under the guise of a foreign invader. In the army of William of Normandy Englishmen were pressed to complete the conquest of England, but in the army of William of Orange, strangers came to awake her sons to begin the work of her deliverance. In the person of the earlier William the Crown of England passed away for the first time to a king wholly alien in speech and feeling; in the later William it in truth came back to one who was even in mere descent, and yet more fully in his native land and native speech, nearer than all that came between them to the old stock of Hengist and Cedric. The one was the first king who reigned over England purely by the edge of the sword, the other the last king who reigned over England purely by the choice of the nation. The coming of each of the men who entered Exeter in such opposite characters marked an era in our history. The unwilling greeting which Exeter gave to the one William and the willing greeting which she gave to the other, marked the wide difference in the external aspect of the two revolutions. And yet both revolutions had worked for the same end; the great actors in both were, however unwittingly

fellow workers in the same cause. It was no small place in English history which belonged to the city whose name stood out in so marked a way in the tale alike of the revolution of the eleventh and the seventeenth centuries. It was no small matter, as we drew near by the western bridge or the eastern isthmus, as we passed where once stood the eastern and the western gates, as we trod the line of the old Roman streets, to think that we were following the march of the Conqueror and the Deliverer; it was no small matter, as we entered the minster of Leofric, Warlewast, and Grandison, to think that the *Te Deum* was there sung alike for the overthrow of English freedom and for its recovery. It was no mean lesson if we had to connect with the remembrances of this ancient city —among so many associations of British, Roman, and English days—the thought that rose above all the rest, the thought that there was no city in the land whose name marked a greater stage in the history of the Conquest of England, that there was none whose name marked a greater stage in the history of her deliverances.

NOTES

FOREIGN honours have been recently falling in showers on the heads of English scientific men. Not long ago the Emperor of Brazil nominated as Knights of the Imperial Order of the Rose, the following gentlemen :—Sir G. B. Airy, Dr. Warren De La Rue, Dr. Birch, Prof. Abel, Major Moncrieff, Capt. Andrew Noble, and Mr. J. Norman Lockyer. The other day, King Oscar II. of Sweden, at his coronation at Stockholm, marked his appreciation of the services rendered by science by conferring distinctions on several men of learning, both Swedes and foreigners. Among the latter were the following eminent scientific men of this country :—Sir Charles Lyell and Sir George B. Airy, named Commanders of the First Class of the Order of the Polar Star; and Professor John Tyndal, Professor Thomas Henry Huxley, and the Director of the Botanical Gardens at Kew (Dr. Joseph Dalton Hooker), named Knights of the same Order.

WE understand that one of the evening discourses at the meeting of the British Association next month will be delivered by Prof. W. C. Williamson, of Manchester, on "Coal and Coal Plants." It is also hoped that Prof. Clerk-Maxwell will deliver a discourse on "Molecules." Several papers on subjects of local interest have also been promised. The following is a list of the vice-presidents and other officers of the Association, the president-elect, as we have already announced, being Prof. A. W. Williamson, F.R.S. :—Vice-Presidents elect: the Earl of Rosse, F.R.S.; Lord Houghton, F.R.S.; W. E. Forster, M.P.; the Mayor of Bradford; J. P. Gassiot, F.R.S.; Prof. Phillips, F.R.S.; John Hawkshaw, F.R.S. Local Secretaries for the meeting at Bradford: the Rev. J. R. Campbell, D.D.; Mr. R. Goddard; Mr. Piele Thompson. Local Treasurer for the meeting at Bradford: Mr. Alfred Harris, jun. General Secretaries: Capt. Douglas Galton, C.B. R.E. F.R.S., Dr. Michael Foster, F.R.S., Trinity College, Cambridge. Assistant General Secretary: George Griffiths, M.A. General Treasurer: William Spottiswoode, F.R.S. Auditors: John Ball, F.R.S.; J. Gwyn Jeffreys, F.R.S.; Colonel Lane Fox, F.G.S. The sections are the ollowing :—A, Mathematical and Physical Science.—President: Prof. Henry J. Stephen Smith, F.R.S. Vice-Presidents: Prof. Balfour Stewart, F.R.S., and Prof. Henrici. Secretaries: Prof. W. K. Clifford, M.A.; J. W. L. Glaisher, Prof. A. S. Herschel, and Prof. Forbes. B, Chemical Science.—President: Dr. W. J. Russell, F.R.S. Vice-Presidents: Prof. Roscoe and I. Lowthian Bell. Secretaries: W. Chandler Roberts, F.C.S.; Dr. Armstrong; and Prof. Thorpe. C, Geology.—President: Prof. Phillips, D.C.L. Vice-President: W. Pengelly Secretaries: Louis C. Miall; William Topley, F.G.S.; R. Tiddeman. D, Biology.—Vice-Presidents: Dr. Beddoe and Prof. Rutherford, M.D. Department of Zoology and Botany.—Secretaries: Prof. Thiselton-Dyer and Prof. Lawson. Department of Anatomy and Physiology.—Secretaries: E. Ray Lankester and Dr. Pye-Smith. Department of Anthropology.—Secretaries: F. W. Rudler, F.G.S., and J. H. Lamprey. E, Geography.—President: Sir Rutherford Alcock. Vice-Presidents: Major-Gen. Sir Henry Rawlinson and John Ball. Secretaries: H. W. Bates, F.R.G.S.; Keith Johnston, F.R.G.S.; and Clements R. Markham, C.B., F.R.S. F, Economic Science and Statistics.—President: Mr. W. E. Forster, M.P. Vice-Presidents: Dr. Farr; Lord Houghton, F.R.S.; E. Baines, M.P. Secretary: J. G. Fitch, M.A. G, Mechanical Science.—President: W. Froude, LL.D. Vice-President: A. Bessemer. Secretaries: H. M. Brunel; J. N. Shoolbred; H. Bauerman.

ON Tuesday the forty-first annual meeting of the British Medical Association was opened in King's College, London, the large hall of which was crowded on the occasion of the general assembly, at 3 o'clock. The General Meeting was presided over by Mr. A. Baker, surgeon to the General Hospital, Birmingham, and president of the Association. After the retiring president had addressed the meeting, Sir W. Fergusson took the chair as president of the Association for the coming year, and read an address of considerable length. It was difficult in the present time, he said, for a president of an association like that to find a suitable subject for an address, as, whatever topic he started with he was immediately surrounded with so many specialists, who of course knew everything better than himself, that he did not know where to stand. The president then entered at much length on the subject of the valley of the Thames and the importance of pure water in a hygienic sense. He suggested that, without having recourse to the expensive process of going to the lakes of Cumberland and Westmoreland for a supply of pure water, there were many streams and rivulets and water sheds where the waters could be confined in lake above lake, and utilised for the supply of London and the large towns. In the evening the Lord and Lady Mayoress held a reception at the Mansion House, which was attended principally by medical gentlemen and their wives and daughters. More than 3,000 were received during the evening.

AMONG the distinguished foreigners now attending the meeting of the British Medical Association in London, may be mentioned—Professors Virchow, Oscar Liebreich, and Baron von Langenbeck, of Berlin; Prof. Busch, of Bonn; Prof. Marey, of Paris; Prof. Chauveau, of Lyons: Prof. Spiegelberg, of Breslau; Prof. Lazarewitch, of Charkow; and Dr. Fordyce Barker, of New York.

ON Monday, the annual meeting of the Cambrian Archæological Association was opened at Knighton, Radnorshire. This Association was established some thirty years ago for the purpose of investigating and preserving the objects of antiquity which abound in the Principality. The first Congress was held at Aberystwith, and the present is the 28th of the series. The President for the past year was Sir J. Russell Bailey, M.P., and the President-elect is the Hon. A. Walsh. The week's programme opened on Tuesday night with the annual meeting and reception of report, after which the President for the year, Sir J. R. Bailey, was to resign the chair to his successor, the Hon. A. Walsh, who was to deliver the inaugural address. The rest of the week will be occupied with excursions, and meetings for the reading of papers.

MR. G. KITCHENER has been elected to the headmastership of the High School, Newcastle-under-Lyne, Staffordshire, in the middle of the Potteries. It is to be the first "First Grade" established as a semi-classical school (*i.e.* without Greek in the

ordinary school course). The time thus made available, will enable more attention to be given to Mathematics and Science. The scheme directs that Chemistry and Design should be specially taught, with a view to the Potter's art. The school is to be opened in the spring of 1875.

IT has long been familiar to geologists that the western and southern coast-line of Scotland is pierced with caves at different levels, indicating former successive levels at which the sea waves worked. Unfortunately, owing to the want of limestone or very calcareous rocks, these caves as a rule present none of that stalagmite deposit which has elsewhere served so abundantly to cover over and preserve the remains of the ancient denizens of our country with traces of the presence of man himself. The caves usually open directly upon the coast, with free exposure to the air, so that their floors show nothing but damp boulders and pools of water from the drip of the roof. Recently, however, a remarkable exception to these ordinary conditions has been observed on the wild cliff line to the south-west of the bay of Kirkcudbright; the Silurian greywacke is there traversed with strings and veins of calcite along lines of joint and fracture, and at one point where an old sea cave occurs, the walls and floor at the cave mouth, and for a few yards inwards, have a coating of solid calcareous matter. Beneath this coating in the substance of the breccia, which extends across the cave mouth, as well as throughout the cave earth behind the breccia, a great quantity of bones, with traces of human occupation, has been found. A systematic investigation of the cave, commenced last autumn, is being carried on under the direction of Mr. A. J. Corrie and Mr. W. Bruce-Clarke, the discoverers of the osseous layer. At the present time the following, among other remains, have been noted: bones of ox, red-deer, goat, horse, pig, pine-marten, rabbit, watermole, and other small rodents, together with numerous remains of birds, and a few frog and fish bones. Intermingled with these occur fragments of bronze, bone needles, and other bone implements, to the number of more than twenty. One piece of worked stone (a fragment of greywacke) has been found, but as yet not a single chip of flint. A full account of the cave will be published as soon as the investigations are completed.

A CONFERENCE of the City Companies, under the presidency of his Royal Highness the Prince of Wales, was held at Marlborough House, on Monday, July 21, with the view of discussing how technical education might be promoted by those companies acting in concert with the International Exhibition. It was unanimously agreed that the City Companies should give their best support to the object which the meeting had in view, and Mr. Cole, C.B., explained that the Commissioners had determined that, during the months of August, September, and October, schools should be admitted to the Exhibition by ticket, at three-pence each scholar, and that, during the month of August at least, frequent lectures each day would be given on the various subjects and processes exhibited. He suggested that the City Companies, in addition to sending their own schools to attend these lectures, might purchase tickets, and place them at the disposal of the London School Board, to enable them to award them as prizes. Such tickets might also be distributed among other public schools.

AT a meeting held at Grosvenor House on July 17, a Provisional and an Executive Committee were formed for the establishment of a National Training School for Cookery in connection with South Kensington. The Committee of Management of the Lectures on Cookery at the International Exhibition have been urged to take this step from the comparatively great success monetarily and otherwise, of these lectures. The meeting agreed that the Executive Committee of the present School for Cookery be an Executive Committee to prepare a scheme and issue the same. The meeting also agreed to the following resolutions:—1. That the establishment of a Training School for Cookery, to be in alliance with the School Boards and Training Schools throughout the country, is most desirable at the present time. 2. That the aim of the proposed school should be to teach the best methods of cooking articles of food in general consumption among all classes. 3. That an Association should be formed with the intention of making the School self-supporting. 4. That it would be prudent to secure a capital, say 5,000*l*., which might be raised by means of donations giving the privilege of nominating students in the School, as well as by means of a guarantee fund; it is estimated that an expenditure of about 1,000*l*. would be required to fit up a practical school or laboratory. The Provisional Committee, containing several Royal and noble names, were authorised to take the necessary measures to establish the school by means of shares, donations, and guarantees. Assuming the necessary capital to be provided—and we hope there will be no difficulty nor delay in doing so—the Executive Committee hope that they may be able, before the end of the year, to establish courses of practical instruction in the kitchen, as well as lectures. Arrangements will be made so that courses may be severally attended by pupil-teachers in training for public education, by domestic servants, and by ladies. The experiment of this school will be first tried in London, and if it succeeds, similar schools will be established in the large towns. We sincerely hope such a laudable scheme will meet with perfect success. All communications on the subject of the school should be addressed to the Secretary (*pro tem.*) of the school, Annual International Exhibitions, Kensington Gore, London, S.W.

ARRANGEMENTS have been made with Mr. P. Simmonds for the delivery each day of six short lectures on the industries illustrated in this year's International Exhibition. These lectures will be commenced on Saturday next.

ON Saturday a deputation from the Trades' Guild of Learning which was formed for the promotion of technical education in the various trades and industries of the United Kingdom, waited upon the Marquis of Ripon at the Privy Council Office, with a view of urging upon the Government the desirability of taking further steps to promote a higher technical education. The deputation included Sir A. Brady, Mr. H. Solly, and others. Sir A. Brady said what the working-men wanted was not money but a fair start. They felt that enough had not been done in utilising the resources of the South Kensington Museum. The Chancellor of the Exchequer had acted very penuriously in the matter. One way in which they could be assisted was by the establishment of a class of instructed teachers and the attaching art schools to the museums. The Rev. Mr. Solly said that the great body of the intelligent artisans, who were largely represented on the council, found that the benefit of the services they received from the Educational Department almost wholly failed to reach themselves. This failure arose principally from the following causes:—First, because the sources of information were not readily accessible as to what the Department really aimed at with a view to assist them. Secondly, the workmen in the East-end of London found the cost of the journey to the South Kensington Museum to be too great in time and money, and therefore they desired that two or three other well-furnished museums should be established in other parts of the metropolis. The next point was that the Department should not only assist classes which had made some progress, but classes in their incipient stages, and which required nursing. The last and most important point of all was, that however able the Government teachers were to instruct in Science and Art, they were not able to give that practical instruction in any trade which the workman might pre-eminently need and desire. The apprenticeship system had practically broken down. The Marquis of Ripon

said that if Mr. Solly's paper were sent in it should receive careful consideration.

NOTWITHSTANDING the vast importance of St. Paul's Cathedral and the impossibility of making up for its loss were it destroyed, until recently it was in imminent danger of being shattered by every thunderstorm that passed over it. The lightning-rods that were supplied to it 120 years ago have long been utterly useless, and from its position, size, and certain peculiarities of structure, the noble building formed a tempting object of attraction to the destructive stroke of lightning. Happily, we learn from the *Telegraphic Journal*, this is no longer the case. The authorities, dissatisfied with the electrical state of the building, upon the report of Mr. John Faulkner, Associate of the Society of Telegraph Engineers, of Manchester, commissioned him to prepare a plan for the fitting of the cathedral with an efficient system of conductors. The plan submitted was approved, and the fitting is now completed. In metallic connection with cross and ball and scrolls are eight copper conductors, each being a ½-inch strand of copper wires. The octagonal strand has been adopted as giving most metal in the least space. These eight conductors then pass to the metallic railing of the Golden Gallery, with which they are in metallic connection. Thence they are carried down to the dome, to the metallic surface of which they are again connected at several portions of their length. Then down the rain-falls, over the leaden roofs of the aisles, in the angles formed by the aisles themselves, again down the rain-falls to the sewers. Further, the choir and nave roofs are connected together by a saddle or conductor stretching over them both, and joined to the conductors proceeding from the summit of the west towers. Even this did not satisfy the zealous care of Mr. Faulkner, who tested, sheet by sheet, the electrical condition of the leads, connecting the worse insulated sheets by copper bands to the better conducting surfaces. Thus the dome, aisle-roofs, and ball and cross, and the two west towers, form one immense metallic conductor, and the danger arising from interior gas-piping is removed; for Coulomb and Faraday have proved beyond doubt that electricity accumulates upon the surface only of bodies. In the sewers, which always afford a moist earth connection, the copper strands are riveted to copper plates, and these again are pegged into the earth. By this means as good an earth connection is obtained at the top of the cross, at the very summit of the Cathedral, as is found in the sewers at its base.

THE Examinations in the Crystal Palace School of Practical Engineering, for the Easter term, commenced last Saturday, and will close on Friday, August 9th. The Autumn Term will commence on Monday, September 8. The Principal will attend in the school from 10 till 4 each day, from Saturday, August 2nd, to Friday, the 8th, to pass Candidates for admission.

AN earthquake occurred at Jamaica at 0.30 A.M. on July 1, which created much alarm. It lasted nearly five seconds.

AMONG Mr. Murray's announcements of forthcoming works are—"Personal Recollections, from Early Life to Old Age," by Mary Somerville; "The Geography of India, Ancient and Modern," by Colonel Yule, C.B.; "The Naturalist in Nicaragua," by Thomas Belt, F.G.S.; and a popular edition of Mr. H. W. Bates's "The River Amazons."

A NEW and cheap edition of Mr. James B. Jordan's "Elementary Crystallography" has been published by Mr. Murby as one of his series of science manuals. To any one commencing the study of crystallography this manual will be very useful, especially as appended to the letterpress is a series of carefully drawn nets for the construction of models illustrative of the simple crystalline forms.

THE report of the annual meeting of the Perthshire Society of Natural Science shows that Society to be in a prosperous and good working condition. The number of members is large, and among them is a fair proportion of workers. We are glad to see that excursions have been started, and hope they will be continued; no richer field, we are sure, than the County of Perth, especially for Botany, exists in this country. The Society, under the energetic management of Dr. Buchanan White, of Dunkeld, is publishing a Fauna and Flora of Perthshire, and it is under its auspices the *Scottish Naturalist* is brought out. During the last summer Mr. J. Allen Harper turned out, for the purpose of acclimatisation, about 7,000 living specimens of the following molluscs: *Helix virgata*, *H. pisana*, and *Bulimus acutus*. The annual address of the president, Col. Drummond Hay, occupies the greater part of the report, and gives many interesting details concerning the birds of Perthshile. The Society has entered on the seventh year of its existence.

THE following are the chief additions to the Brighton Aquarium during the past week:—4 Corkwing Wrasse (*Crenilabrus melops*); 7 Pogge (*Agonus cataphractus*); 1,000 Prawns (*Palæmon serratus*); several groups of *Serpula contortuplicata* and *Alcyonium digitatum*. Four young rough-hounds (*Scyllium canicula*) have been hatched from eggs laid during the last week in January. The period of their development in *ovo* is therefore six months. A large number of young Squid (*Loligo vulgaris*) have also been hatched from spawn brought in by fishermen.

THE additions to the Zoological Society's Gardens during the last week include an Ocelot (*Felis pardalis*) from America, presented by Mr. A. B. Keymer and Mr. C. C. Lovesy; a Togue Monkey (*Macacus pileatus*) from Ceylon, presented by the Sergeants of the 1st Batt. Scots Fusiliers; a grey Ichneumon (*Herpestes griseus*) from India, presented by Mr. G. S. Daintry; a starred Tortoise (*Testudo stellata*) from India, presented by Capt. C. S. Sturt; two lesser black-backed Gulls (*Larus fuscus*), presented by Mr. C. W. Wood; two crested Pigeons (*Ocyphaps lophotes*), hatched in the Gardens; a Hoffmann's Sloth (*Cholopus hoffmanni*) from Panama, and a black-eared Marmoset (*Hapale jacchus*) deposited.

METEOROLOGY IN HAVANNA *

TO judge from the pamphlets mentioned below, the practical study of Meteorology seems to be pursued at the Cuba Observatory with diligence and a harvest of good results. The care and skill with which they are compiled must lead to the conclusion that science will receive very valuable aid both in meteorological and magnetic research from this station of the West Indies.

The observatory is situated at a height of 19·297 metres above the sea level, in N. lat. 23° 8′ 14″·5, its longitude being 76° 9′ 42″·8 west of San Fernando, and therefore 82° 22′ 6·95 west of Greenwich. The first volume is a yearly meteorological and magnetic report, and consists entirely of monthly tables and curves of the daily mean results of the barometer, thermometer, tension, humidity, wind, evaporation, rain, and state of sky. For each month the daily maximum, minimum, and mean values are given, and then follows a table of the monthly means for every even-hour of the day and night. The direction and force of the wind are shown on a circular diagram, and the mean daily values of the barometer, thermometer, tension, and humidity are exhibited by broken lines. Rain curves are added from May.

Regular two-hourly observations of the Magnetic Declination were commenced on April 1, 1871, and the same details are given as for the barometer, &c. To these were added at the

* Observaciones Magneticas y Meteorologicas del real Colegio de Belen de la compania de Jesus en la Habana, de 30 Nov. 1870 a 30 Nov. 1871.
Memoria de la Marcha regular o periodica, et irregular, del Barometro en la Habana des de 1858 a 1871 inclusive, por el R. P. B. Vines, S.J.
Observaciones correspondientes al mes de Octubre de 1870, con la descripcion de los huracanes ocurridos en la Isla en dicho mes.

commencement of the following month similar observations of the horizontal magnetic force. For these elements of terrestrial magnetism two-hourly, as well as daily mean, curves are traced for each month.

In the general table that closes the report, we notice that the prevailing wind never deviates, in any season, more than 13° 31′ from the east, and in spring it is only 3° 36′ N. of E. The rainfall for the seasons given in millemetres was in winter, 71·1; in spring, 181·0; in summer, 480·0; and in autumn, 547·2; the number of rainy days being respectively 13, 15, 33, and 39.

The coincidence of magnetic disturbances with local storms, with hurricanes in Florida and St. Thomas, with Auroras visible in distant lands, and with similar magnetic perturbations in England, was remarked in August, September, and November. The frequent disturbances of the needle noted in October certainly do not agree with photograghic records in England, this month having been remarkably free from perturbations of this nature.

The second book contains the results of a continued series of barometric observations between the years 1858 and 1871. The reliance we may place on the accuracy of the work can be estimated from the fact, that the correction of 1·07mm. for sea level was the result of 2,000 comparisons.

A very regular double period is apparent in the daily range, which may be represented by the expression $h = k \sin (a+t) + k' \sin (b+2t)$; but the range for the day hours is somewhat in excess of that of the night. The minima occur at 2—4 AM. and 3—4 P.M., and the maxima at 9—10 A.M. and 10 P.M., the times varying slightly with the seasons.

In December, January, and February, the amplitude of the daily range is greatest, and then gradually decreasing it attains its minimum in June and July. This confirms the law of Ramond, cited by Kaemtz, that the amplitude of the barometric range within the tropics is least in the rainy season. This annual variation of the daily range is, remarks our author, the more worthy of note, as it is directly opposed to what has been observed in Europe, where the range is greatest in summer. This remark appears to me to require some modification, for on turning to the monthly mean range observed, for instance, at Stonyhurst, during the last quarter of a century, I find a perfect agreement with the annual variation for Cuba. The mean values for the several months at Stonyhurst are 1·448, 1·415, 1·378, 1·167, 0·970, 0·896, 0·869, 0·927, 1·217, 1·323, 1·451, 1·449. These means are, it is true, obtained from the extreme monthly maxima and minima, but our author informs us that the amplitude of the extraordinary oscillations, if we eliminate the four greatest which were due to hurricanes, resembles the mean annual variation of the range, being greatest in January and least in July. The mean values of the extraordinary oscillations being almost identical in November, December, February, and March, give this annual daily range curve at Cuba a singular symmetry. The periodic recurrence of summer storms at fixed hours will account for the diminution of the range in that season.

The mean values of the Daily Range have been deduced by several methods: 1. From the absolute maxima and minima, by which the irregular oscillations are not sufficiently eliminated. 2. By Humboldt's method, from the maxima and minima at fixed hours. 3. By Kaemtz's method, from the arithmetical means of the maxima and minima. 4. From Bravais formula, $R = \sqrt{\frac{d^2 + d_2^2 + .. d_n^2}{n}}$; d, d_2 . . . being the differences between the monthly mean and those of certain fixed hours. There is a striking agreement in the results from all these methods, but the second shows in certain cases signs of a suspicious irregularity.

Besides the Daily Range, and an annual variation of this range, there exists a yearly variation of the mean value analogous to the diurnal, having its principal maximum and minimum in January and October, and secondary ones in July and May. This double inflexion of the mean annual curve is peculiar to Cuba, since there is generally in the same latitude only a single maximum in January, and a minimum in July.

The abnormal inflexion occurs during the month of June, July, August, and September. Kaemtz, in his "Météorologie," who is followed by Marie Davy, fixed the principal minimum in August, but this and other lesser differences arise probably from not eliminating extraordinary perturbations, and from the confessed imperfection of his series of observations.

The observations of fourteen years are insufficient to determine any certain law respecting the years of hurricanes; but an inspection of the yearly curves shows that 1865 and 1870 are distinguished from the rest by the almost identity of the means for February, March, and April, followed by a rapid rise from May to July, a fall from July to October, and a still more marked rise from October to January.

The third pamphlet gives a very interesting and detailed account of the terrible hurricanes that caused such wide-spread desolation in the October of 1870. The first storm occurred on the 7th and 8th, the second on the 19th and 20th.

The author adopts the theory of cyclones first enunciated by Redfield in 1831, and since accepted and modified by many eminent meteorologists. Situated N. of the Equator he considers the storm to be rotating in the direction from E. to W. through N. and the centre to be at the same time moving N.W. within the tropics, and N.E. in higher latitudes. The resultant path he finds to be a spiral wrapped round a parabola, the folds of the spiral being closest at the apex of the curve. The position of the centre or vortex is given at any moment by the height of the barometer and the direction of the wind. The barometer being lowest at the centre, the reading of the mercurial column, corrected for daily range and for the particular wind, furnishes data for determining the distance of the centre, whilst the angular bearing of the latter is known from its being at right angles to the direction of the wind, and to the rigtht hand of an observer facing the wind. This follows necessarily from the circular motion of the cyclone, and falls, as a particular case, under the general law of Buys Ballot, since we know that the barometer is lowest at the vortex. The latter is thought to move in a cycloidal curve with loops at the cusps, which just fall on the parabolic trajectory. The vortex is thus almost always to the E. of the parabola. The double motion of translation and rotation causes the effects of the hurricane to be much more disastrous in the N. hemisphere to the E. of the parabolic path than on the W. side, and the velocity of the wind at a given distance from the vortex for any points of the compass may be found from the formula $V = \sqrt{t^2 + r^2 + 2tr \cos \theta}$, where t and r are the velocities of translation and rotation, and θ is measured from the E. point when the storm is moving N. The calm at the centre of the cyclone gives a ready means of estimating the velocity of translation. The storm of the 7th was felt from the 4th to the 13th, the maximum humidity lasting till the 12th. The rate at which the vortex crossed the island was only four miles an hour, and this remained almost constant throughout. The second storm was much more sudden and rapid, and the increasing rate, from 9½ to 20 miles an hour, at which the vortex was travelling, showed that the second branch of the parabola had been reached before passing Cuba.

Equal heights of the barometer combined with the directions of the wind enable the meteorologist to lay down the parabolic trajectory with considerable accuracy, either from observations at a single station, or at several. Thus on the 7th at 2 P.M. the corrected barometer read the same at Havannah and at Cienfuegos, the wind being S. by W. at the latter, and N.E. at the former station, the vortex was therefore at that time S.E. of Havannah, and a few degrees N. of W. from Cienfuegos, but equally distant from the two places. The more rapid changes and greater fall of the barometer, together with the increase in the velocity of the wind, show that the storm passed more centrally over Havannah than over Cienfuegos. The discharges of electric fluid were very intense, and at Cardenas an appearance similar to the aurora borealis was visible for ten minutes. The magnetic needles were much disturbed. The inundations from the rising of the sea were very destructive, and on the 7th the existing wind favoured the rise. This rise under the centre of the cyclone seems to follow from the removal of pressure, and the inrush of air of different temperatures fully accounts for the heavy rainfall. The diminution of atmospheric pressure is also offered as a probable explanation of the slight shocks of earthquake, due perhaps to the violent expansion of certain gases confined within the cavities that abound in the island.

A careful consideration of the accounts published in the local papers, and a personal inspection of the localities, tended strongly to confirm the results of theory.

Cuba, from its situation just within the Tropic of Cancer, and at the entrance to the Gulf of Mexico, is admirably placed for the study of these cyclonic storms, and eight of those which have been best observed are traced on a map appended to the pamphlet, showing that in most cases the apex of the parabolic curve is not far from the island. It is a subject of congratulation that an observatory so well conducted, and so situated, has, by

the kind assistance of Sir E. Sabine, been provided with a set of magnetic instruments by which the connection of terrestrial magnetism with the most violent of our tropical storms may be thoroughly investigated.

SCIENTIFIC SERIALS

THE *Monthly Microscopical Journal* for this month commences with a paper by Mr. W. H. Dallinger and Dr. Drysdale, entitled "Researches on the Life History of a Cercomonad: a lesson in Biogenesis,"—in which they describe, as the result of a very thorough and long-continued series of observations, the life history of a new Cercomonad, which is thus summarised:—"When mature, it multiplies by fission for a period extending over from two to eight days. It then becomes peculiarly amœboid; two individuals coalesce, slowly increase in size, and become a tightly distended cyst. The cyst bursts, and incalculable hosts of immeasurably small sporules are poured out, as if in a viscid fluid, and densely packed; these are scattered, slowly enlarge, acquire flagella, become active, attain rapidly the parent form, and once more increase by fission." They show also that the granules can withstand a temperature much higher than can the mature forms.—Dr. Royston-Pigott makes remarks on the Confirmation given by Dr. Colonel Woodward to the "Colour test," which comes into play in proving that spherical aberration is reduced to a minimum in objectives.—Dr. Dawson remarks on Mr. Carruthers' views of Protataxites, the latter author having described it as a gigantic seaweed, called by him *Nematophycus*. Dr. Dawson gives further reasons for maintaining his original opinion that it is phænogamous.—Prof. Rupert Jones continues his excellent papers on Ancient Water-fleas of the Ostracodous and Phyllopodous tribes (Bivalve Entomostraca). This is followed by an article on the pathological relations of the diphtheritic membrane and the croupous cast, by Mr. Jabez Hogg, which would have been more in place in a medical journal. The Wenham-Toller controversy is maintained by the latter and some others, and there are abstracts of several interesting papers, with notices of Vol. III. of Stricker's Histological Manual and Dr. Frey's work on the microscope.

Poggendorff's Annalen der Physik und Chemie: No. 4, 1873.—In this number appears the sixth of the series of papers on internal friction of gases, by O. E. Meyer and F. Springmühl. The authors, having formerly examined the transpiration of atmospheric air through capillary tubes, have further observed that of carbonic acid, of oxygen, and of hydrogen, and find the Poiseuille law to hold good for these gases also. In most of the experiments the gas streamed from one vessel into another containing the same gas at lower pressure; but the case of a gas streaming into a vessel containing another kind of gas was also examined. The velocity of transpiration proved the same, and there was no countercurrent of the second gas through the capillary tube, as in the case of diffusion. In an appended note the authors criticise some experiments of von Lang.—Dr. Röntgen gives details of a careful determination of the relation of specific heat at constant pressure to that at constant volume, for the gases, air, carbonic acid, and hydrogen; the mean numbers obtained being 1·4053, 1·3052, and 1·3852 respectively. The writer discusses these results in their bearing on the mechanical equivalent of heat, and the velocity of sound, and compares the work of previous experimenters on the subject.—The concluding part of a paper by F. Rudorff on solubility of salt mixtures appears in this number; and A. Potier replies to certain strictures, by Quincke, on some recent observations of his, as to reflection from metals and glass. Among the remaining matter may be noted an important memoir by G. Rose (communicated to the Berlin Academy), on the behaviour of the diamond and graphite on being heated. The author describes and illustrates the regular forms produced in the diamond through combustion, treats of the general heating effects where air is excluded and where it is not, the natural blackening of diamonds, the so-called carbonate, and connected topics.—A note by F. Zöllner, detailing further experiments to show that electrical currents are produced by current water (a statement which was questioned by Beetz a short time since), also deserves attention.

Der Naturforscher, June 1873.—Among the more important papers in this issue we may note the account of Pettenkofer and Voit's recent researches on the value of fat as a nutritive substance. They find that fat is very largely absorbed from the alimentary canal, but after long feeding with great quantities of fat the absorption becomes less; also that (contrary to a common opinion), fat is much more readily decomposed into simpler products than albumen. The decomposition of food-fat depends on that of albumen, on the amount of albumen present, and on the proportion of it fixed in the organs, to what is in circulation. The results given in this memoir have an important practical bearing. Another physiological paper treats of the influence of food on the structure of digestive organs: the experimenter, H. Crampe, thinks that the nature of food, alone, affords no sufficient explanation of the differences found in these.—An article on the loss of free nitrogen in putrefaction describes some interesting experiments by Messrs. König and Kiesow. In physics and chemistry we find notes on the change of length and electricity produced by the galvanic battery, on the action of electricity on carbon compounds, on Dr. Gladstone's new air battery, on the action of electrical force on non-conductors, &c.—There are two French astronomical papers, one on an attempt to measure the diameter of Sirius; the other, on MM. Cornu and Baille's new determination of the mean density of the earth. Geology, meteorology, and other branches of science, are also represented.

SOCIETIES AND ACADEMIES

PARIS

Academy of Sciences, July 28.—M. de Quatrefages, president, in the chair.—The following papers were read:—On the exponential function, by M. Hermite.—An examination of the theory of the thrust of earthworks against their sustaining walls, by M. de Saint-Venant. This was a criticism on M. Curie's late papers on this subject.—On a proposed regular service of train transports between Dover and Calais, by M. Dupuy de Lôme. The author, in conjunction with Mr. Scott Russell, has devised a method of transporting entire trains by means of large steamers. Part of the paper was devoted to a project of a new port west of Calais, as that place is useless for the purpose; at Dover everything is ready for such a purpose, there being now 40 ft. of water at the end of the Admiralty pier at low tide. The proposed scheme would be able to carry 800,000 passengers, and 870,000 tons of goods annually.—On electric cauterisation applied to surgery, by M. Sédillot.—New researches on the solar diameter, by Father Secchi. The author had found the sun's diameter, observed spectroscopically in the lines C and B, to be less than that given by the Nautical Almanac; he hence advocated the use of monochromatic images for making such determinations, and replied to some objections of S. Respighi, who, on repeating these experiments, agreed with the almanac.—M. Ledieu's paper on thermo-dynamics was continued.—On a new method of condensing liquefiable bodies held in suspension in gases, by MM. THE ENDOWMENT OF RESEARCH

V.

ALTHOUGH it is not within the purpose of these articles to propose an elaborate scheme in which the Endowment of Research in all its branches may be completely provided for, yet it may be reasonably expected that some suggestions should be now put forward to serve as an answer to those who urge the hopeless impracticability of the attempt, and as a foundation upon which a definite plan may be constructed, by the help of criticism, from those who can speak with authority in their own particular subjects.

In the first place, it is above everything important that the need of a systematic organisation of a central character with entire freedom of action should be at once recognised. It is absurd to suppose that the lack of pecuniary means can be the main difficulty which has hitherto, in the richest country in the world, hindered original investigation in the Sciences. The natural harvest of scientific discoveries which England ought annually to reap has rather been checked by the irregularity with which the labourers have been rewarded, and the comparative indignity with which they have been treated. For a certain class of scientific investigations of a strikingly practical character the public will always be willing to sanction large parliamentary grants; but for the permanent Endowment of Research, and the continuous support in a worthy position of the researchers, not only the aid of the nation at large, but the wealth and the prestige of our ancient Universities are required. There is, of course, no reason for any interference with the valuable work at present accomplished by the London Societies, but their work is of a different character. The new organisation would not grow into a monopoly, but would naturally take to itself those departments of knowledge which are least cared for, and in which the benefits of endowments will be most felt. Its wealth would enable it to be liberal, and its public position would impose just that amount of responsibility which should protect it from those dangers to which its wealth might render it exposed.

It is impossible to give a precise account of the actual manner in which the endowment should be distributed. To advance a crude scheme would be disadvantageous to the cause at heart, and to descend into detail would be to offer an unnecessary advantage to the enemy. Much must be left for the future to develope, and much must be left to the men to whom the administration is entrusted. If a scheme were to be worked out in detail in accordance with the demands of Science as understood at the present day, and if strict rules were to be adopted for its application, it might very well happen that before many years have gone our new Foundation would become an obstruction rather than a help to the advancement of Science. That a system may be vague, and yet eminently useful, and that its managers may safely be trusted with powers almost irresponsible, may be learnt from the example of the Smithsonian Institution in the United States. It is there found that to the Secretary of that institution, who at present is Professor Henry, may be confided the management of about 8,000*l.* a year, subject only to the nominal control of a board of American politicians, upon the trust to further "the advancement and diffusion of knowledge." Many incidental lessons may be gathered from the manner in which the funds of this Institution are applied. There are no professors, and no oral instruction of any kind: money is advanced to individual investigators, not to support them while engaged in their scientific labours, but merely to provide the apparatus and the materials necessary for their researches; but the largest part of the funds would appear to be devoted to the publication of the work which they have encouraged, and which under the title of "Smithsonian Contributions to Knowledge," are well known all over Europe. In this case, therefore, Research is indirectly endowed by means of a moderate pecuniary assistance to the investigators, whereas in Germany it is indirectly endowed through the professoriate; but our proposal is that nothing but a direct endowment will satisfy the peculiar wants of this country.

There is yet a further reason why any plan now put forward should be purposely indefinite and incomplete. The funds which the colleges will ultimately yield can only fall in very gradually. It is, according to the modern practice, quite impossible to make anything out of the present holders of fellowships, who are in most cases young men, who may retain their appointments if they choose up to the limit of their lives. It would also, for manifest reasons, be inexpedient to divert each several fellowship as it becomes vacant from its present destination. The machinery of the University organisation is so delicate that the occasions for introducing changes into it must of necessity be left to those who are best acquainted with the manner in which it works. Many years must elapse before that portion of the College revenues to which original research is now putting in a claim can be handed over to this account. In the meantime it is the duty of all those who support this claim not to dispute about details, but to force a hearing for that principle which they advocate in common, and which, when once publicly recognised, will render easy the remainder of the task.

It is not, however, difficult to point out roughly the lines in which the endowment will have to proceed, and so to meet by anticipation the apparent objections which are certain to be alleged. The form the endowment should take, the persons who are to be entrusted with the distribution, and the guarantee that the appointments shall not degenerate into sinecures, are all matters which require explanation. With regard to the first question, it is necessary to clear away a prevalent misunderstanding, which would seem to be based upon the existing system of Fellowships. It is not an essential part of the new scheme that a given number of Research Fellowships should be forthwith founded, to be awarded to young students who have passed successful examinations in Science. The very opposite course is the one which would commend itself to those who are aware of the evils of the present practice. The number of the new appointments should not be fixed; at first it should be small, but capable of increase as the suitable candidates come for-

ward: and above all, the principle of selection should be other than that of competitive examination. The man with the peculiar talents and proved industry which are wanted for the post must be carefully sought for, and the place must be made for him, rather than the man manufactured for the place. The managing body must be allowed perfect liberty either to found a new Fellowship for the particular man, or to refuse to fill up a vacant appointment. All our Research Fellows will be, according to the German system, in extraordinary posts. From this it will follow that direct endowment of this kind, though the ultimate aim of our efforts, and by far the principal part of our scheme, is not the manner in which a beginning should be made. This form of endowment, so far as can at present be foreseen, must be comparatively exceptional, and therefore, when the right man is found, his position should be made one of handsome emolument, and it ought to be rendered impossible that he should be negligently passed over.

The other ways in which research should be endowed may be regarded in the ultimate scheme as chiefly subsidiary to this, but in the order of time they must come first. The funds of the Colleges which are not wanted for teaching purposes, may at once be utilised for our object in an infinite number of indirect ways. They ought to be regarded as an abundant reservoir, from which may be continually drawn generous encouragement and ready help for those who happen to be carrying on some special investigation in any branch of Science. The Colleges should take the place which was occupied in England some century ago by those noble and wealthy patrons to whom Science, Art, and Literature all owe so much. They should give in no grudging spirit, for they may be assured that an apparent waste in one direction will be amply compensated by the unlooked-for returns which they will reap in another. By throwing open their libraries, by building museums and laboratories, by supplying instruments or needful materials, by paying for laborious calculations or expensive publications, as well as by subsidising any particular investigation, they would breed up, so far as any artificial means can, that race of men from whom the selection must afterwards be made for their new Fellowships. To those who have had unfortunate experience of the management of college business, and of the sort of matters which come before a college meeting, such a reform as has been sketched out will doubtless appear as a visionary ideal; yet it might be realised with very little trouble if the richest Colleges would transfer some of the attention which they now bestow upon ecclesiastical and educational interests, to the cause of original research, and when realised, the result would be more nearly akin than the present, to that which the original statutes contemplated.

To answer the two other questions proposed need not take long, for an implicit reply to them has already been given. Fortunately, modern Science has taken such definite shape, and is pursued in such full publicity, that each branch has even now, at its head, certain acknowledged leaders, to whose judgments and recommendations in their special subjects, all deference is due. Until the Universities and the Colleges become sufficiently penetrated with the new scientific spirit, it will be natural that they should endow research under the guidance of the scientific societies, and of course it will be always necessary that they should be fully conscious of their responsibilities to the public for the appointments they confer upon the candidates, however selected. The analogy of the Smithsonian Institution will here again come in, for its assistance is never given in any case unless after a favourable report from a Commission of scientific men, who are experts in the particular matter submitted to them.

With regard to the objection that the plan will inevitably tend to the foundation of a new store of sinecures, it is not incumbent to say more than that scientific posts, where the duty itself is of absorbing pleasure, are the least likely to degenerate in the way suggested, and that the in sinuation comes with an ill grace from those who are the present recipients of benefactions which they do so little to deserve. C.

ON LOSCHMIDT'S EXPERIMENTS ON DIFFUSION IN RELATION TO THE KINETIC THEORY OF GASES

THE kinetic theory asserts that a gas consists of separate molecules, each moving with a velocity amounting, in the case of hydrogen, to 1,800 metres per second. This velocity, however, by no means determines the rate at which a group of molecules set at liberty in one part of a vessel full of the gas will make their way into other parts. In spite of the great velocity of the molecules, the direction of their course is so often altered and reversed by collision with other molecules, that the process of diffusion is comparatively a slow one.

The first experiments from which a rough estimate of the rate of diffusion of one gas through another can be deduced are those of Graham.* Professor Loschmidt, of Vienna, has recently† made a series of most valuable and accurate experiments on the interdiffusion of gases in a vertical tube, from which he has deduced the coefficient of diffusion of ten pairs of gases. These results I consider to be the most valuable hitherto obtained as data for the construction of a molecular theory of gases.

There are two other kinds of diffusion capable of experimental investigation, and from which the same data may be derived, but in both cases the experimental methods are exposed to much greater risk of error than in the case of diffusion. The first of these is the diffusion of momentum, or the lateral communication of sensible motion from one stratum of a gas to another. This is the explanation, on the kinetic theory, of the viscosity or internal friction of gases. The investigation of the viscosity of gases requires experiments of great delicacy, and involving very considerable corrections before the true coefficient of viscosity is obtained. Thus the numbers obtained by myself in 1865 are nearly double of those calculated by Prof. Stokes from the experiments of Baily on pendulums, but not much more than half those deduced by O. E. Meyer from his own experiments. The other kind of diffusion is that of the energy of agitation of the molecules. This is called the conduction of heat. The experimental investigation

* *Brande's Journal* for 1829, pt. ii., p. 74, "On the Mobility of Gases," Phil. Trans., 1863.

† Sitzb. d. k. Akad. d. Wissench, 10 März. 1870.

of this subject is confessedly so difficult, that it is only recently that Prof. Stefan of Vienna,* by means of a very ingenious method, has obtained the first experimental determination of the conductivity of air. This result is, as he says, in striking agreement with the kinetic theory of gases.

The experiments on the interdiffusion of gases, as conducted by Prof. Loschmidt and his pupils, appear to be far more independent of disturbing causes than any experiments on viscosity or conductivity. The interdiffusing gases are left to themselves in a vertical cylindrical vessel, the heavier gas being underneath. No disturbing effect due to currents seems to exist, and the results of different experiments with the same pair of gases appear to be very consistent with each other.

They prove conclusively that the co-efficient of diffusion varies inversely as the pressure, a result in accordance with the kinetic theory, whatever hypothesis we adopt as to the nature of the mutual action of the molecules during their encounters.

They also show that the co-efficient of diffusion increases as the temperature rises, but the range of temperature in the experiments appears to be too small to enable us to decide whether it varies as T^2, as it should be according to the theory of a force inversely as the fifth power of the distance adopted in my paper in the Phil. Trans. 1866, or as $T^{\frac{3}{2}}$ as it should do according to the theory of elastic spherical molecules, which was the hypothesis originally developed by Clausius, by myself in the Phil. Mag. 1860, and by O. E. Meyer.

In comparing the co-efficients of diffusion of different pairs of gases, Prof. Loschmidt has made use of a formula according to which the co-efficient of diffusion should vary inversely as the geometric mean of the atomic weights of the two gases. I am unable to see any ground for this hypothesis in the kinetic theory, which in fact leads to a different result, involving the diameters of the molecules, as well as their masses. The numerical results obtained by Prof Loschmidt do not agree with his formula in a manner corresponding to the accuracy of his experiments. They agree in a very remarkable manner with the formula derived from the kinetic theory.

I have recently been revising the theory of gases founded on that of the collisions of elastic spheres, using, however, the methods of my paper on the dynamical theory of gases (Phil. Trans. 1866) rather than those of my first paper in the Phil. Mag., 1860, which are more difficult of application, and which led me into great confusion, especially in treating of the diffusion of gases.

The co-efficient of interdiffusion of two gases, according to this theory, is—

$$D_{12} = \frac{1}{2\sqrt{6\pi}} \frac{V}{N} \sqrt{\frac{1}{w_1} + \frac{1}{w_2}} \; \frac{1}{s^2_{12}} \qquad (1)$$

where w_1 and w_2 are the molecular weights of the two gases, that of hydrogen being unity.

s_{12} is the distance between the centres of the molecules at collision in centimetres.

V is the "velocity of mean square" of a molecule of hydrogen at 0° C.

$$V = \sqrt{\frac{3p}{\rho}} = 185{,}900 \text{ centimetres per second.}$$

* Sitzb. d. k. Akad., Feb. 22, 1872.

N is the number of molecules in a cubic centimetre at 0° *C.* and 76 cm. *B.* (the same for all gases).

D_{12} is the co-efficient of interdiffusion of the two gases in $\frac{(\text{centimetre})^2}{\text{second}}$ measure.

We may simplify this expression by writing—

$$a^2 = \frac{1}{2\sqrt{6\pi}} \frac{V}{N}, \quad \sigma_{12}{}^2 = \frac{1}{D_{12}} \sqrt{\frac{1}{w_1} + \frac{1}{w_2}} \qquad (2)$$

Here a is a quantity the same for all gases, but involving the unknown number N.

σ is a quantity which may be deduced from the corresponding experiment of M. Loschmidt. We have thus—

$$s_{12} = a\,\sigma_{12} \qquad (3)$$

or the distance between the centres of the molecules at collision is proportional to the quantity σ, which may be deduced from experiment.

If d_1 and d_2 are the diameters of the two molecules.

$$s_{12} = \tfrac{1}{2}(d_1 + d_2).$$

$$\text{Hence if } d = a\,\delta \;.\;.\;.\; \sigma_{12} = \tfrac{1}{2}(\delta_1 + \delta_2). \qquad (4)$$

Now M. Loschmidt has determined D for the six pairs of gases which can be formed from Hydrogen, Oxygen, Carbonic Oxide, and Carbonic Acid. The six values of σ deduced from these experiments ought not to be independent, since they may be deduced from the four values of δ belonging to the two gases. Accordingly we find, by assuming

TABLE I.

$\delta(H) = 1{\cdot}739$
$\delta(O) = 2{\cdot}283$
$\delta(CO) = 2{\cdot}461$
$\delta(CO_2) = 2{\cdot}775$

σ_{12}	Calculated $\frac{1}{2}(\delta_1 + \delta_2)$	Observed $\sqrt{\frac{1}{D}\sqrt{\frac{1}{w_1} + \frac{1}{w_2}}}$
For H and O	2·011	1·992
For H and CO	2·100	2·116
For H and CO_2	2·257	2·260
For O and CO	2·372	2·375
For O and CO_2	2·529	2·545
For CO and CO_2	2·618	2·599

NOTE.—These numbers must be multiplied by 0·6 to reduce them to (centimetre-second) measure from the (metre-hour) measure employed by Loschmidt.

The agreement of these numbers furnishes, I think, evidence of considerable strength in favour of this form of the kinetic theory, and if it should be confirmed by the comparison of results obtained from a greater number of pairs of gases it will be greatly strengthened.

Evidence, however, of a higher order may be furnished by a comparison between the results of experiments of entirely different kinds, as for instance, the coefficients of diffusion and those of viscosity. If μ denotes the co-efficient of viscosity, and ρ the density of a gas at 0° C. and 760 mm. B, the theory gives—

$$\frac{\mu}{\rho} = a^2 \sqrt{\frac{2}{w}} \quad \frac{1}{d^2} \qquad (5)$$

so that the following relation exists between the viscosities of two gases and their coefficient of interdiffusion—

$$D_{12} = \frac{1}{2}\left(\frac{\mu_1}{\rho_1} + \frac{\mu_2}{\rho_2}\right) \qquad (6)$$

Calculating from the data of Table I., the viscosities of the gases, and comparing them with those found by O. E. Meyer and by myself, and reducing all to centimetre, gramme, second measure, and to 0° C.—

TABLE II.

Coefficient of Viscosity

Gas.	Loschmidt.	O. E. Meyer.	Maxwell.
H	0·000116	0·000134	0·000097
O	0·000270	0·000306	
CO	0·000217	0·000266	
CO_2	0·000214	0·000231	0·000161

The numbers given by Meyer are greater than those derived from Loschmidt. Mine, on the other hand, are much smaller. I think, however, that of the three, Loschmidt's are to be preferred as an estimate of the absolute value of the quantities, while those of Meyer, derived from Graham's experiments, may possibly give the ratios of the viscosities of different gases more correctly. Loschmidt has also given the coefficients of interdiffusion of four other pairs of gases, but as each of these contains a gas not contained in any other pair, I have made no use of them.

In the form of the theory as developed by Clausius, an important part is played by a quantity called the *mean length of the uninterrupted path of a molecule*, or, more concisely, the *mean path*. Its value, according to my calculations, is

$$l = \frac{1}{\sqrt{2}\,\pi s^2 N} = \frac{\sqrt{12}}{\sqrt{\pi}\,V}\frac{1}{\delta^2} * \qquad (7)$$

Its value in tenth-metres (1 metre × 10^{-10}) is

TABLE III.

For Hydrogen . .	965	Tenth-metres at 0° C. and 760 B
For Oxygen . .	560	
For Carbonic Oxide	482	
For Carbonic Acid	430	

(The wave-length of the hydrogen ray *F* is 4,861 tenth-metres, or about ten times the mean path of a molecule of carbonic oxide.)

We may now proceed for a few steps on more hazardous ground, and inquire into the actual size of the molecules. Prof. Loschmidt himself, in his paper "Zur Grösse der Luftmoleciile" (Acad. Vienna, Oct. 12, 1865), was the first to make this attempt. Independently of him and of each other, Mr. G. J. Stoney (Phil. Mag. Aug. 1868), and Sir W. Thomson (NATURE, March 31, 1870), have made similar calculations. We shall follow the track of Prof. Loschmidt.

The volume of a spherical molecule is $\frac{\pi}{6} s^3$, where s is its diameter. Hence if N is the number of molecules in unit of volume, the space actually filled by the molecules is $\frac{\pi}{6} Ns^3$.

This, then, would be the volume to which a cubic centimetre of the gas would be reduced if it could be so compressed as to leave no room whatever between the molecules. This, of course, is impossible; but we may, for the sake of clearness, call the quantity—

$$\epsilon = \frac{\pi}{6} Ns^3 \qquad (8)$$

the ideal coefficient of condensation. The actual coefficient of condensation, when the gas is reduced to the liquid or even the solid form, and exposed to the greatest degree of cold and pressure, is of course greater than ϵ.

Multiplying equations 7 and 8, we find—

$$s = 6\sqrt{2}\,\epsilon\, l \qquad (9)$$

where s is the diameter of a molecule, ϵ the coefficient of condensation, and l the mean path of a molecule.

Of these quantities, we know l approximately already, but with respect to ϵ we only know its superior limit. It is only by ascertaining whether calculations of this kind, made with respect to different substances, lead to consistent results, that we can obtain any confidence in our estimates of ϵ.

M. Lorenz Meyer† has compared the "molecular volumes" of different substances, as estimated by Kopp from measurements of the density of these substances and their compounds, with the values of s^3 as deduced from experiments on the viscosity of gases, and has shown that there is a considerable degree of correspondence between the two sets of numbers.

The "molecular volume" of a substance here spoken of is the volume in cubic centimetres of as much of the substance in the liquid state as contains as many molecules as one gramme of hydrogen. Hence if ρ_0 denote the density of hydrogen, and $\mathfrak{b}$ the molecular volume of a substance, the actual coefficient of condensation is—

$$\epsilon' = \rho_0\,\mathfrak{b} \qquad (10)$$

These "molecular volumes" of liquids are estimated at the boiling-points of the liquids, a very arbitrary condition, for this depends on the pressure, and there is no reason in the nature of things for fixing on 760 mm. B. as a standard pressure merely because it roughly represents the ordinary pressure of our atmosphere. What would be better, if it were not impossible to obtain it, would be the volume at − 273° C. and ∞B.

But the volume relations of potassium with its oxide and its hydrated oxide as described by Faraday seem to indicate that we have a good deal yet to learn about the volumes of atoms.

If, however, for our immediate purpose, we assume the smallest molecular volume of oxygen given by Kopp as derived from a comparison of the volume of tin with that of its oxide and put

$$\mathfrak{b}(O = 16) = 2{\cdot}7$$

we find for the diameters of the molecules—

TABLE IV.

Hydrogen	5·8 tenth-metres.
Oxygen	7·6
Carbonic Oxide . .	8·3
Carbonic Acid . .	9·3

The mass of a molecule of hydrogen on this assumption is

$$4{\cdot}6 \times 10^{-24} \text{ gramme.}$$

The number of molecules in a cubic centimetre of any gas at 0° C. and 760 mm. B. is

$$N = 19 \times 10^{18}.$$

Hence the side of a cube which, on an average, would contain one molecule would be

$$N^{-\frac{1}{3}} = 37 \text{ tenth-metres.}$$

J. CLERK-MAXWELL

* The difference between this value and that given by M. Clausius in his paper of 1858, arises from his assuming that all the molecules have equal velocities, while I suppose the velocities to be distributed according to the "law of errors."

† Annalen d. Chemie u Pharmacie V. Supp. bd. 2, Heft (1867).

THE LAST GLACIAL EPOCH

On the Cause, Date, and Duration of the Last Glacial Epoch of Geology, and the Probable Antiquity of Man. With an investigation and description of a new movement of the Earth. By Lieut.-Colonel Drayson, R.A., F R.A.S. (London: Chapman and Hall, 1873.)

THE author of this work allows the existence of the motion of rotation of the earth on its axis and its revolution round the sun. That motion, however, of the axis of the earth, to which is due the precession of the equinoxes, is to him a great stumbling block. He denies the possibility of this motion as generally accepted, and gives us a theory of his own, which is very novel, and the results of which are startling in the extreme.

Lieut.-Colonel Drayson either knows nothing of dynamics or despises the science: the one key he makes use of to unlock the secrets of astronomy is geometry; he does not believe in the existence of a change in the plane of the ecliptic, and apparently is not aware that the attractions of the other planets on the earth *must* produce periodic changes in the plane of the earth's orbit. In consequence of this he persuades himself that all astronomers teach (and perhaps believe) that while the pole of the earth is describing a circle round the pole of the ecliptic, the obliquity of the ecliptic, which is the angular distance between these poles, is constantly changing. He calls this a geometrical impossibility, and nobody would hesitate to agree with him that it is; but astronomers would at once deny that they either teach or believe anything of the kind. The popular belief is that the pole of the earth describes a circle of radius 23° 28′ round the pole of the ecliptic as a centre, and that the whole circle would be described in something over 25,000 years.

Lieut.-Colonel Drayson tells us that the true motion of the pole of the earth is in a circle whose radius is 29° 25′ 47″, and whose centre is at a distance of 6° from the pole of the ecliptic. He attempts to prove this, and, we believe, has succeeded in persuading himself that he has proved it. He does this by showing that this particular circle will satisfy all the necessary conditions, as he puts them, and also (we assume) as he understands them. The author next proceeds to deduce the consequences of this motion. His circle would be described in 31,840 years, so that at intervals of 15,920 years the obliquity of the ecliptic would vary as much as 12°. The consequence of this would be that about 13,700 B.C., Great Britain would have had during the winter an arctic climate, the sun in lat. 54° not being 1° above the horizon at the winter solstice, and during the summer a tropical climate. This is supposed to have been the last glacial epoch, and the author has such confidence in his theory that he promises us glacial epochs every 31,840 years.

The book, as a whole, we look upon as most unsatisfactory. Had the author mastered the principles of dynamics, he probably would not have been led by a mistaken interpretation of movements which he only partly understood, into the fatal error of attempting to solve one of the most abstruse problems in astronomy by mere geometry. The days of such attempts were, we hoped, past for ever.

The motion of the earth's axis is well illustrated by the motion of a boy's top when it is spinning with its axis inclined to the vertical. Every one has seen a top while spinning on its own axis, revolve round the vertical with approximately constant speed, while its axis remained inclined to the vertical at an approximately constant angle: but who has seen a top spinning so that its axis revolved with constant speed round a line inclined to the vertical at an angle of 6°, or any other angle? Till Lieut.-Colonel Drayson produces a top which will do this, thereby proving experimentally that such a motion is possible, or till he demonstrates by analysis the possibility of such a motion, we shall feel confident in rejecting his theory of the earth's motion, as the theory of a paradoxer, and in regarding the cause of the last glacial epoch as a secret still unknown.

DR. SMITH ON FOODS

Foods. By Edward Smith, M.D., F.R.S. (Henry S. King and Co.)

THE tendency during the last thirty years or so to the equalisation, throughout the country, of the prices of the several articles employed as food, has done much to make the subject of Foods one of much greater interest to a larger class of the community than heretofore. The products of a district being now scarcely, if at all, cheaper than those that can be obtained from a considerable distance, a knowledge of the relative nutritive value of foods becomes essential to a larger number. We therefore look with great interest to the results of Dr. Edward Smith's considerable experience, especially with regard to some of the articles of more modern introduction.

The classification adopted is the following. Foods are first divided into solid, liquid, and gaseous, an arrangement which has the disadvantage of separating closely-allied substances from one another, milk having to be considered removed from cheese and butter. The solid foods are then divided into animal and vegetable, and each of these are subdivided into nitrogenous and non-nitrogenous. The source, composition, and alimentary properties of each article are then discussed in detail. The analyses are mainly those of Fresenius, Frankland, Wanklyn, and other well-known chemists. The author in most cases is able to introduce the results of his own observations on the physiological action of each substance, which are also to be found in the Transactions of the Royal Society. Taking arrowroot as a fair example of the manner in which the subject is treated, after a short account of its origin we find that "the proximate elements in 100 parts are water 18·0, and starch 82·0; so that it is or should be free from nitrogen. There are 2,555 grains of carbon in 1 lb. . . . Ten grains of arrowroot when thoroughly consumed in the body produce heat sufficient to raise 10·06 lbs. of water 1° F., which is equal to lifting 7,766 lbs. one foot high." The author observes that when eaten alone on an empty stomach it gives no sense of satisfaction, but one of malaise. Eating 500 grains increased the emission of carbonic acid 0·154 grains per minute. The rate of respiration was somewhat lessened, and the pulse was increased four beats per second (*sic*). As each subject is similarly described, it is evident that

there is a large amount of needless repetition, for the estimation of the heat of combustion is a simple calculation, which might have been made once for all with reference to each proximate principle, especially since the bare facts, as they are put, convey but little idea to the general reader. The chemistry of foods is very superficially and imperfectly treated, not nearly so full as it deserves; and the botany would have been better if a more thorough study of materia medica had been undertaken. There is one sentence we have in vain attempted to understand. When speaking of the sweet chestnut, the author, after remarking that at present it may be regarded as a luxury, says, "The first step to a great extension of its use would be to make the ordinary horse-chestnut a safe and agreeable food, since it grows in our climate, and could be obtained in large quantities." How this can be, seems extremely difficult to understand; as is well known, the two fruits having nothing whatever to do with one another.

The descriptions of the various methods that have been proposed for the preservation of meats which have to travel long distances and through hot climates is very complete and clear. The preference is given to the method of heating, and that adopted by Mr. Jones, in which the meat is heated in vacuo, to 280° F., in the cans, is fully described. It is shown, however, that by this process the meat is stewed, and over-stewed, not roasted nor boiled. In this, and all similar processes, it is found impossible to expel all the air without over-cooking the meat.

Another subject of particular interest which is discussed is the preservation of milk. Two methods, it appears, are adopted in America, one in which the milk is simply evaporated to one-fourth its original volume, when it will often keep for a month, and another in which sugar is added; by the latter process it remains good for an indefinite time, and contains about one-third of its weight of sugar. The author agrees sufficiently with Dr. Daly in his condemnation of the employment of this preserved milk for infants, to quote an article by him which appeared last year in the *Lancet*.

Extract of meat, especially Liebig's, occupies the greater part of one chapter, and we think the author has done good service in setting in a clear and unmistakable light the true value of that expensive luxury. He shows that its chief value depends on the meaty flavour it is capable of imparting, and that its nutritive value is *nil*. He remarks—"Its proper position in dietetics is somewhat more than that of a meat-flavourer, but all that is required for nutrition should be added to it. . . . Used alone for beef-tea it is a delusion." That this is correct is evident from a consideration of the method by which it is prepared, for "during the process, all the fat and as much of the gelatin and albumen as can be extracted are removed from the solution of flesh, whilst the fibrin, being insoluble, is necessarily left behind. Hence there remain water, salts, osmazone, and the extractives of flesh, or, in general terms, the flavouring matters and the salts of meat—thus leaving out all that is popularly (and correctly) regarded as nutritious."

Many tables are given to show the effects of different substances on the respiration, pulse, exhalation of carbonic anhydride and aqueous vapour. There seems to be a want of association between the great mass of facts, which must have been the result of long and continuous labour; and they are undoubtedly put forward in a way which is not best suited to convince the scientific student. For example, the effects on the pulse, &c., of tea dissolved in water is given in full, but under the head of water no mention is made of its physiological action, though decidedly, by itself it changes the pulse rate, if nothing else.

Several recipes of the fourteenth century are quoted from "Cury," a copy of ancient manuscript recipes of the master cook of Richard the Second. There are also many scriptural references, and a very inappropriate abstract of an incident which occurred at the Worship Street Police Court.

OUR BOOK SHELF

A Manual of Metallurgy. By George Hogarth Makins, M.R.C.S., F.C.S., &c. (Ellis and White, 1873.)

THE present edition of this work presents a marked improvement over those which have preceded it, but it is still far from being all that even a small manual might be. In the preface the author expresses a hope that the volume, "in which the leading points connected with the principal metals are set forth, may be found useful," and as there are singularly few metallurgical works in the English language, we have but little doubt that this hope will be realised. Mr. Makins has long enjoyed the reputation of being a most accurate assayer, and the descriptions of the processes of assaying gold and silver are careful and valuable. The portion of the work which is the least satisfactory is that devoted to iron.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. No notice is taken of anonymous communications.*]

The Huemul

THE Huemul of Chili and Patagonia, referred to in NATURE, pp. 253 and 263, was *first* recognised in modern scientific literature by MM. Gay and Gervais, who in the *Annales des Sciences Naturelles* for 1846 (v., p. 91), showed that the so-called *Equus bisulcus* of Molina, was a species of Deer (*Cervus*), which they proposed to call *Cervus chilensis*.

In Gay's "Fauna Chilena" (plates 10 and 11), the female and skull are figured. Concerning the nomenclature of species, I have published some remarks in the last volume of the "Annals of Natural History" (ser. 4, vol. vi. p. 213), to which I beg leave to refer such of your readers as are desirous of further information on this subject.

Perception and Instinct in the Lower Animals

IN answer to Mr. George J. Romanes (NATURE, August 7) I beg to say that I particularly inquired of my friend whether he had been to or near his old house on the day the dog returned, or shortly before, and he assured me that "he had never been near it since he left." I ought to have stated this in my account of the circumstance.

I shall make no further remarks on the subject, because I believe that nothing satisfactory can be arrived at till experiments of the nature indicated in my last letter have been systematically carried out.

ALFRED R. WALLACE

Collective Instinct

THE writer of one of the books on Indian sport relates how he saw a herd of antelopes, driven backwards and forwards by four wolves, which surrounded the herd, each guarding a diffe-

rent side, until at length the antelopes passed over a ditch in which a fifth wolf lay concealed. This wolf, jumping up as the antelopes crossed, secured one of them, upon which his four companions joined him, and assisted in making a meal of the captured animal.

A civilian of the N.W.P.* told me that he witnessed a very similar occurrence in Oudh. He saw two wolves standing together, and shortly after noticing them was surprised to see one of them lie down in a ditch, and the other walk away over the open plain. He watched the latter, which deliberately went to the far side of a herd of antelopes standing in the plain, and drove them, as a sheep dog would a flock of sheep, to the very spot where his companion lay in ambush. As the antelopes crossed the ditch, the concealed wolf jumped up, as in the former case, seized a doe, and was joined by his colleague.

Here are two well-authenticated instances of an action or series of actions requiring the exercise of combined sagacity of a high degree on the part of two or more individual animals, being performed in exactly the same way by different members of the same species. Was the method employed by the wolves to secure their food, which they could not have caught single-handed, the result of separate experience or of inherited habit? The identical character of the stratagem employed in the two cases points to the latter.

I have noticed some similar instances of collective action on the part of other animals which I believe to be as much inherited as the habitual actions of individual animals. I have constantly seen a flock of pelicans when on the feed form a line across a lake, and drive the fish before them up its whole length, just as fishermen would with a net. The capture of the fish is rendered doubly easy by this method. I have witnessed exactly a similar plan pursued by a large number of Ganges crocodiles which had been lying or swimming about all day in front of my tent, at the mouth of a small stream which led from some large inland lakes to the Ganges. Towards dusk, at the same moment, every one of them left the bank on which they were lying, or the deep water in which they were swimming, and formed line across the stream, which was about twenty yards wide. They had to form a double line, as there was not room for all in a single line. They then swam slowly up the shallow stream, driving the fish before them, and I saw two or three fish caught before they disappeared.

Where a large number of individuals constantly repeat in continuation the same action, it is possible that the younger members may merely copy the older members of the species, and so carry on the habit generation after generation. This is less likely where few are concerned, as in the case of the wolves. A pair of wolves are probably of the same age. It is a marked habit of some species of birds to hunt in pairs, and assist each other in the capture of their prey. The *wokhab*, or common eagles of the Indian plains, hunt in this way. When one of the pair misses in its swoop, the other descends on the victim before it has time to make a fresh attempt to escape. The circumstance that some species of birds of prey are in the habit of combining for the capture of their food, while others hunt singly, would tend to prove that the combined habit is as much inherited as the habits of individuals are known to be.

Gregarious actions, which require combination of purpose on the part of two or more individuals, entail the exercise, if not of a higher degree of intelligence, at any rate of a greater number of intelligent qualities than the isolated actions of single individuals. This class of actions possesses, therefore, a special interest. Those instances in which different individuals perform totally different acts for the attainment of the same end, as in the case of the wolves, are the most interesting, as requiring the most intelligent qualities. I should be glad to learn if any of your readers have ever witnessed or heard of the stratagem described above being employed by wolves for the capture of their prey.

Ants and "the Taint of the Hand"

IN NATURE, July 24, Mr. James D. Hague, writing on the habits of ants, attributes their dislike to the place across which a finger has been drawn to "the taint of the hand."

Now, Sir, I have frequently drawn a line with a piece of chalk across the track of ants, and observed in them the same symptoms of dislike as Mr. Hague's ants showed to the finger-mark.

I have also drawn a small circle with chalk round one or more ants, who will seek a spot untouched by the chalk through which to make their escape; but should there be no such opening, they will presently cross the circle. If, however, this enclosure be made upon a perpendicular wall, &c., they will frequently drop to the ground rather than walk across the line.

Now, as I have never observed this same dislike—exhibited by dropping—of the "taint" when ants have been running over my hands, and as the chalk-line has the same effect as the finger-mark, may it not be something else than the "taint of the hand" to which the ants object when their usual track is interfered with?

Stamford, Aug. 8 G. E. C.

Venomous Caterpillars

WITH reference to a paper published by Mr. Murray in NATURE, vol. viii. p. 7, on Venomous Caterpillars, I wish, in corroboration, to add my testimony from personal experience, that a species of caterpillar has the power of inflicting a very painful sensation (I will not say wound, as such was not visible) by its sting.

In 1868, when travelling in company with Capt. Street in the Burmese forests on a botanical trip, and whilst in the act of detaching a specimen plant of *Dendrobium farmerii*, from the naked branch of a tree, I felt a severe and painful sting on my thumb. On examination I noticed I had seized hold of a large caterpillar lodged amongst the roots of this orchid. It was about two inches long, clothed with erect hairs; its colour was a reddish brown, the lower part of the abdomen being darker, with well-developed legs.

My thumb continued painful for three days; it was considerably swollen, the skin having a drawn glazed appearance.

The Burmese told me that this kind of caterpillar was exceedingly venomous, and one fellow was particularly consoling by informing me that unless the pain subsided in three days the sting might prove fatal. I am inclined to think that the caterpillar for self-protection has the power of detaching these hairs; whether any propelling force is present at the time of detachment it would be difficult to prove.

I found steeping my thumb in Eau de Cologne gave me the greatest relief.

Whether these hairy caterpillars have a special venom or otherwise I do not feel qualified to express my opinion either one way or the other; but I lean towards the conclusion that the irritation is set up by the mechanical action of the spine during its penetration of the skin, and my reason for inclining towards this opinion is because we have a somewhat parallel case in the irritation caused by the hairs of the prickly pear.

I was present when an officer was thrown off his horse into a prickly pear hedge; he suffered the greatest pain, and could not bear the parts, where these minute spines had penetrated the skin, to be touched. On his being placed in a warm bath the relief was almost immediate, especially to those parts capable of total immersion, and this I attribute to the prickles or hairs floating and becoming removed from the skin by the oscillatory motion of the water.

Madras, July R. BENSON

Abnormal Ox-eye Daisy

IN 1868 I gathered among the ruins of Pompeii a very curious monstrosity of the common ox-eye daisy. The flower and flower-stalk were confounded into a strap-shaped mass which was fringed with the florets. I showed it to Prof. Wyville Thomson, who told me it was an instance abnormal in this species, of the form of inflorescence which is normal in the coxcomb.

JOSEPH JOHN MURPHY

Old Forge, Dunmurry, Aug. 1

Canarese Snakes

FAM. *Erycidæ*, Gen. *Gongylophis*? Sp. ?—Captured in Mangalore, December 2. Gape wide; fangs in sup. and inf. maxillaris.

Body moderate, tail short, obtuse scales, smooth, 48;—ventrals narrow, 197, terminating with three rows of scales between last ventral and anal; latter entire. Subcaudals single, 24, last forming conical point.

Head flat, not very distinct from neck, scaled, with following exceptions:—Rostril, anterior frontals; nasals (double, with the nostril between); mental; upper (12) and lower labials.

Gular depression; small groove anterior to orbit; orbit surrounded by scales; eye small, pupil vertical, iris silver grey, with dark longitudinal streak.

Rudimentary hind limbs, scales small, greatly increasing in size as they approach ventrals; colour above greyish brown, vertebral series of dark brown irregular spots, confluent towards neck; lateral series of dark brown spots. Belly whitish, mottled with dark brown; post orbital dark brown streak.

Length of specimen 21 in. A sand snake of sluggish disposition, especially during day-time.—Did not attempt to bite when handled.

Fam. *Elapidæ*. Gen. *Ophiophagus*. *O. Elaps*.—The Hamadryad, a male specimen caught by snake charmers at Agumbi, Western Ghauts, South Canara. Since dead, the skin having been secured by a member of the Basil Mission. I measured the snake when alive, and found it to be 10 ft. 6 in. but it was probably more, as it strongly resisted being stretched out. Colour brownish black, with about thirty bands on fore part of body, formed by dull yellowish interstitial skin. A yellow V mark with the apex towards head on upper part of hood: dark band beneath hood.

The Canarese call the snake "Kalinga havre," and state it to be common in the jungles along the Ghauts. I hope before long to procure a live specimen.

Fam. *Crotalidæ*. Gen. *Trimesurus*. Sp.—Scales 21, ventrals 153, subcaudals 58. Head scales strongly heeled. Colour dark reddish brown, irregularly marked with pale reddish brown, forming pale centred lateral ocelli. A series of pale yellow irregular dots arranged in a lateral stripe. This specimen has been forwarded to Dr. J. Shortt, F.L.S.

A specimen of the *Daboia elegans*, the Tic Polongo of Southern India and Ceylon, was lately brought me having the belly pure white, unmarked with the usual brown spots.

A Tahsildar in a Northern Talug reports the occurrence of a large venomous snake, black above and red beneath. This I think will prove to be *Callophis* (*Elaps*) *nigrescens*.

Mangalore. E. H. PRINGLE

BRITISH MEDICAL ASSOCIATION.—ABSTRACT OF DR. SANDERSON'S ADDRESS ON PHYSIOLOGY

IN his address on Physiology before the British Medical Association, Dr. Sanderson gave a *résumé* of the most important physiological work that has been done during the past year. Commencing with the circulation of the blood, he considered it to be resolved into several constituent processes, such as arterial pressure, velocity of blood-current, and contraction or relaxation of muscular fibre. He referred to a very elegant method adopted by Dr. Marey of Paris, and illustrated by him to the members of the Association, by which the influence of arterial resistance on the heart's rapidity may be demonstrated on the excised heart of the tortoise, the number of pulsations being proved to vary inversely as the *resistance* and not as the blood pressure, a fact previously known, but not before so clearly illustrated. He then referred to the observations of Mr. Dewar and Dr. M'Kendrick, in which they have shown that the normal electromotive force in the optic nerve is reduced in intensity when it is receiving the impression of light, a "negative variation" of the current being the result. Dr. Jackson's and Dr. Ferrier's pathological and physiological studies as to the localisation of the sources whence originate some of the voluntary movements in certain parts of the surface of the brain were shown to have a very important bearing on the progress of cerebral physiology; Dr. Ferrier having arrived at a method by which one at least of the highest functions of the nervous system can be brought under the control of experimental investigation. With reference to the part played by Bacteria in the living organism, Dr. Sanderson remarked that observations respecting them were, though very numerous, not sufficiently connected to allow of a ready summary; the facts added during the year being, first, that in certain persons apparently healthy, and in many animals, organisms belonging to this class are always found in the blood; secondly, that in all acute inflammations which are attended with the destruction of living tissue, Bacteria are to be found in the exudation liquids; and thirdly, that in relapsing fever living beings are present in the blood, which exhibit characteristic forms.

Dr. Sanderson in the latter part of his address gave many reasons in favour of the combination of the study of medicine with that of physiology. It has been said that theoretical physiology has led to injurious medical treatment, *e.g.*, to the over-feeding and over-stimulating treatment of disease; to the unreasonable disuse of venesection; to the neglect of antimony and other so-called antiphlogistics, and to the purgative treatment of cholera. But are the theories on which these changes of treatment have been based, physiological in the proper sense? Decidedly not. Taking the action of mercury as an example. It has been proved to have no influence in increasing the secretion of the liver; nevertheless, blue-pill is of undoubted value in certain well-defined disturbances of the digestive organs. From these facts, however, it is not right to assume that mercurial remedies are useless, or that they act beneficially by exciting the secretion of bile; such inferences are not physiological, but result from the manner in which practical men throw undeserved discredit upon Science by attempting to apply its facts without any sufficient knowledge of their bearing. Therefore it is highly desirable for the welfare of both Medicine and Physiology that a distinct line of demarcation should be drawn between them.

The speaker then entered upon subjects of a more purely medical nature, giving an excellent *résumé* of the present position of our knowledge respecting the nature of fever and pyrexia generally.

LAKES WITH TWO OUTFALLS

SOME years ago a discussion took place concerning the possible or actual existence of lakes possessing outlets into two distinct watersheds, so as to render one watershed continuous with the other. If even one such lake could be shown to exist, the question would of course be resolved in the affirmative. I have frequently heard mentioned as an instance a certain lake at the summit of the Romsdal in Norway, and having lately spent a day or two at each end of this lake, I have taken advantage of the opportunity to examine each of the outlets with care. I have thus convinced myself that it ought not to be quoted as a proof of the natural existence of such lakes.

The piece of water in question is called the Læsöskougens Vaud, or sometimes the Lesje Værks Vaud; it lies between the posting stations of Mölmen and Lesje Jernværks, at an elevation of 1,992 Norwegian feet, or 2,050 English feet above the sea level, occupying, for a length of about seven miles, the highest part of the great valley which in its south-eastern part is known as the Gudbrandsdal, and in its north-western part as the Romsdal. There can be no doubt that from the eastern extremity of the lake flows a small stream, which forms one of the sources of the Laagan or Logen River, while from the western extremity descends a much larger stream, which is the principal source of the river Rauma. Since the Logen, after passing through Miösen Lake, becomes a part of the great river Glommen, and thus falls into the Skaggerat at Frederichshald, while the Rauma reaches the sea through the Romsdal Fjord, it follows that the whole of the south-western part of Norway is encircled by water.

On examining the eastern exit of the lake, however, it soon becomes apparent that the outflow is artificially regulated. The water is retained at this end by a great

barrier of boulders, gravel, and sand, which has doubtless been heaped up by glacial action. At the north-eastern extremity this barrier is narrowed until it resembles an artificial embankment, and at this point a channel has apparently been cut for the purpose of supplying water power to the works situated immediately below. The actual stream of water forming the first source of the river Logen had a depth at the time of my visit of three feet, with a width of about six feet; it flowed through a rectangular channel, paved at the bottom and sides with large boulders, and sustained by timbers. Although these timbers are now nearly rotted away, it is evident that the channel had at some time or other been carefully formed. The water power is at present used for a saw-mill, but it was, no doubt, originally employed to furnish the blast for an old iron furnace, which has given the name of Lesje Jernværks to this place. The furnace has been abandoned, as I was informed, for the last eighty years, and from the dates upon the ironwork of a neighbouring house I think it likely that the works were erected at least 150 years ago, a length of time which would perhaps be sufficient to account for the natural appearance of the stream below the works.

I also examined the western exit of the lake with care. The first break in the level of the water occurs at a wooden bridge which slightly restrains the outflow. The stream flows strongly here, with a width in all of about 45 ft., a maximum depth of about 2 ft. 9 in. at the time of my visit, and an average depth of about 2 ft. After falling about 9 in. at this point, the river flows in a steady deep stream through a perfectly natural channel for about an English mile, with a very slight fall, after which its descent becomes gradually accelerated. I have no doubt that this considerable stream forms the natural outlet of the lake, but that a lowering of the water in the lake to the extent of three or four feet would stop this outflow altogether.
